LIST OF MAPS IN VOLUME II.

	PAGE
BELGIUM AND LUXEMBURG	48
DOMINION OF CANADA AND NEWFOUNDLAND	696
EASTERN CANADA AND NEWFOUNDLAND	704
WESTERN CANADA	705

Among the more important articles in this Volume are the following :

BEE.. . . .	Professor J. ARTHUR THOMSON.	BRIDGE (Game).. .	R. F. GREEN.
BEECH, BIRCH . . .	JOHN NISBET, D.Cec.	BRIDGE (Engineering)	Professor SIR T. HUDSON BEARE.
BEE-KEEPING.. . .	R. STEELE.	BRIQUETTES	Professor W. A. BONE.
BEER	A. L. STERN, D.Sc., F.I.C., Chemist and Brewer to Messrs Bass, Ratcliff, and Gietton, Limited.	BRISBANE.....	W. A. JOSE.
BEETHOVEN....	SIR GEORGE GROVE.	BRITISH MUSEUM.....	ARUNDELL ESDAILE.
BELTS.. . . .	Professor SIR T. HUDSON BEARE.	BROADS... ..	WALTER RYE, G. A. STEPHEN.
BENEDICTINES..	Rev. E. G. CODY, O.S.B.	BROCHS, BRONZE AGE.	JOSEPH ANDERSON, LL.D.
BERGSON	HENRY BARKER.	BROWNE, SIR THOMAS	Rev. THOMAS DAVIDSON.
BERKELEY	Professor A. CAMPBELL FRASER.	BROWNING.. . . .	G. K. CHESTERTON.
BERLIOZ.	CHARLES L. GRAVES.	BUCHANAN, GEORGE...	Professor P. HUME BROWN, LL.D.
BETTING, BIGAMY.....	Sheriff J. M. IRVINE, K.C., LL.D.	BULGARIA... ..	Dr E. J. DILLON.
BEWICK	J. M. GRAY.	BUNYAN... ..	Rev. JOHN BROWN, D.D.
BIBLE.. . . .	Rev. Professor H. T. ANDREWS, D.D.	BUOY	Messrs D. & C. STEVENSON.
BIBLICAL CRITICISM	Rev. Professor A. S. PEAKE, D.D.	BURGESS.	Sheriff J. M. IRVINE, K.C., LL.D.
BILHARZIA.. . . .	Professor J. ARTHUR THOMSON.	BURKE	THOMAS KIRKUP.
BILLIARDS....	SYDENHAM DIXON.	BURMA	JOHN NISBET, D.Cec.
BIMETALLISM... .	Professor J. SHIELD NICHOLSON; MARY T. RANKIN, Ph.D.	BUTER, SAMUEL.. .	R. A. STREATFIELD.
BIOLOGY.. . . .	Professor PATRICK GEDDES.	BUTTER	JAMES B. LOVE.
BIRD	Professor J. ARTHUR THOMSON.	BUTTERFLY.. . . .	Professor J. ARTHUR THOMSON.
BIRMINGHAM..	CHARLES LINNELL.	BY-LAWS... ..	Sheriff J. M. IRVINE.
BLAKE.	J. M. GRAY.	BYRON... ..	Professor SAINTSBURY.
BLASTING, BOMB.	Col. Sir H. W. BARLOW, Bart., C.B., C.M.G.	BYZANTINE ART....	DAVID MACGIBBON.
BLEACHING.	A. B. STEVEN.	C....	Dr HENRY BRADLEY.
BLEACHING POWDER .	W. INGLIS CLARK, D.Sc.	CABBALA.. . . .	Professor W. E. ADDIS.
BLIND.....	Principal Sir FRANCIS J. CAMPBELL, Lady CAMPBELL.	CAGE-BIRDS, CANARY.	C. W. GEDNEY.
BLOCKADE.....	Captain H. M. JOHNSTONE, R.E.; Admiral Sir R. TUPPER, K.C.B.	CAIRO	Professor STANLEY LANE POOLE.
BLOOD.. . . .	Dr ALEXANDER GOODALL.	CALCULATING	MACHINES .. Major-general BARBAGE.
BOAT	J. R. BARNETT of Messrs G. L. Watson & Co.	CALCULUS	A. Y. FRASER.
BOCCACUOIO. . . .	WALTER WHYTE.	CALDERON.....	FRANCIS HINDES GROOME.
BOILER	Professor SIR T. HUDSON BEARE.	CALENDAR.....	J. S. MACKAY, LL.D.
BONE	Professor DAVID HEPBURN.	CAMBRIAN SYSTEM...	Professor JAMES GEIKIE.
BOOKBINDING.	GEORGE A. STEPHEN.	CAMEO.....	JAMES PATON.
BOOK-KEEPING.....	JOSEPH PATRICK, C.A.	CAMOENS.	Professor P. HUME BROWN, LL.D.
BOOTS AND SHOES .	JAMES PATON.	CANAL	Professor SIR T. HUDSON BEARE.
BOROUGH.. . . .	Prof. HENRY GOUDY, D.C.L., LL.D.	CANCER	Dr E. F. BASHFORD.
BORROW.	FRANCIS HINDES GROOME.	CANDLE.. . . .	WILLIAM LOVE.
BOTANY... ..	Professor PATRICK GEDDES.	CANNON, CARTRIDGE...	Col. Sir H. W. BARLOW, Bart., C.B., C.M.G.
BOTHWELL.. . . .	FRANCIS HINDES GROOME.	CANOE... ..	JOHN MACGREGOR and T. H. HOLDING.
BOULDER-CLAY.....	Professor JAMES GEIKIE.	CANONISATION... .	T. G. LAW, LL.D.
BOWLS....	J. R. FAIRMAN.	CANON LAW....	Rev. R. F. LITTLEDALE, LL.D.
BOYS' BRIGADES...	SIR WILLIAM A. SMITH.	CANTICLES.....	Rev. Professor H. T. ANDREWS, D.D.
BRAIN.....	Dr ALEXANDER BRUCE, Dr A. NINIAN BRUCE.	CAPE OF GOOD HOPE,	CAPE TOWN
BRAKES.. . . .	Professor SIR T. HUDSON BEARE.	CAPE TOWN	J. LIDDELL GEDDIE.
BRAXY	Professor J. R. U. DEWAR.	CAPILLARITY.....	Professor WILLIAM THOMSON.
BREAD, BISCUITS.....	Dr DRINKWATER.	CAPITAL.	THOMAS KIRKUP.
BREAKWATER. . . .	Messrs D. & C. STEVENSON.	CAPITAL PUNISHMENT.	Sheriff J. M. IRVINE, K.C., LL.D.
BREECH-LOADING. . .	Col. Sir H. W. BARLOW, Bart., C.B. C.M.G.	CARBON.. . . .	W. INGLIS CLARK, D.Sc.
BREED	Professor J. ARTHUR THOMSON.	CARBONIFEROUS	SYSTEM.....
BRIBERY.	Sheriff J. M. IRVINE, K.C., LL.D.	CARBONIFEROUS	SYSTEM.....
BRICK.	JAMES PATON.	CARDS.....	HENRY JONES ('Cavendish').
		CARLYLE.....	W. WALLACE, LL.D.
		CAROL.. . . .	A. H. BULLEN.
		CARPETS.....	ALEXANDER GALLETT, JAMES PATON.
		CARVING.....	W. SCOTT MORTON.
		CASTLE.....	DAVID MACGIBBON.
		CATARACT.....	Dr R. A. LUNDIE.

A great many of the articles named above are new; others written for earlier issues of this Encyclopædia have been so thoroughly revised by their authors as to be virtually new. In addition to these many other revisers have taken part, including Professor J. A. S. WATSON (on Agriculture), Mr CHARLES MORRIS (on America), Mr C. INGLIS CLARK and Mr WILLIAM MORISON (Chemistry), Dr MARY T. RANKIN (Economics), Sir ANDREW FRASER and Mr G. E. SHEPHERD (India), Sheriff IRVINE and Sheriff DUNBAR (Law), Professor WILLIAM PEDDIE (Mathematics and Physics), Dr JOHN D. COMRIE (Medicine), Mr R. C. MOSSMAN (Meteorology), Captain H. M. JOHNSTONE, R.E. (Military subjects), Admiral Sir REGINALD TUPPER, K.C.B. (Naval subjects). The article BULGARIA makes use of unpublished official sources.

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Beaucaire, a town in the French department of Gard, on the right bank of the Rhone, opposite Tarascon, with which it is connected by a suspension-bridge, 14 miles SSW. of Avignon. Vessels enter its harbour by a canal communicating with the Mediterranean. A great

fair, established in the 13th century, was once one of the principal occasions of trade between France, Italy, and the East, and was attended by 300,000 strangers. The fair is still the scene of a brisk trade in silks, wines, oil, southern fruits, and leather. Pop. 7000.

Beauce, a district of France, partly in the departments of Loir-et-Cher and Eure-et-Loire, contains some of the finest corn-land in France, and in early summer shows an almost uninterrupted plain of waving corn. Its capital is Chartres.

Beauchamp, ALPHONSE DE, historian and publicist, born at Monaco in 1767, entered the Sardinian military service, but in 1792, on the outbreak of the war with France, refused to bear arms against the republic, and obtained his discharge. Being, however, suspected of treasonable designs, he was imprisoned for some months. After his liberation he returned to Paris, where, on the fall of Robespierre, he obtained a situation in the office of the minister of police, and had the surveillance of the press. Here he commenced his *Histoire de la Vendée et des Chouans* (3 vols. Paris, 1806; 4th ed. 1820), for which Fouché supplied the materials. As this work displeased the emperor, Beauchamp was banished to Rheims, but was recalled in 1811, and again received a subordinate appointment, which he lost in 1814. At the Restoration he received a small pension, and he died 1st June 1832. Beauchamp's numerous historical works include histories of Brazil, Peru, the campaign of 1814-15, and a life of Louis XVIII.; and to him have also been ascribed the *Mémoires de Fouché*.

Beauclerk, TOPHAM (1739-80), who figures in Boswell's *Johnson* as the loved and intimate friend of the lexicographer, was the only son of Lord Sydney Beauclerk and a grandson of the first Duke of St Albans. He had the easy air of a man of the world who had seen much and who could describe what he had seen; his conversation was lively, and his tastes in science and literature wide and eclectic. During his friend's last illness Johnson said he 'could walk to the extent of the diameter of the earth to save Beauclerk,' and after his death wrote to Boswell, 'Poor dear Beauclerk, his wit, his folly, his acuteness and maliciousness, his merriment and reasoning are now over. Such another will not often be found among mankind.' In 1768 he had married DIANA (1734-1808), eldest daughter of the second Duke of Marlborough, two days after her divorce from Lord Bolingbroke. An artist of ability, she is known through Bartolozzi's engravings. See Birkbeck Hill's various works on Dr Johnson and his circle (1878-90), and Miss Steuart Erskine's *Lady Diana Beauclerk* (1903).

Beaufort, an Angevin town of 4000 inhabitants, in the French department of Maine-et-Loire, 19 miles E. of Angers. Its ancient castle came into the hands of the Lancaster (q.v.) family at the end of the 14th century, and gave name to the natural and afterwards legitimated sons of John of Gaunt. The Tudor (q.v.) claim to the throne arose from the marriage of the Earl of Richmond with Margaret, daughter of John Beaufort, Duke of Somerset, whose son ascended the throne as Henry VII. Charles Somerset, natural son of the third Duke of Somerset, was created Earl of Worcester in 1514; the fifth earl was raised in 1642 to the marquissate of Worcester, and the third marquiss in 1682 to the dukedom of Beaufort.

Beaufort, (1) a town and port, North Carolina, at the mouth of Newport River, has a good harbour, and some trade in rosin and turpentine; pop. 3000.—(2) A town and port of South Carolina, on Port Royal Island, and terminus of Port Royal Railroad, 14 miles from the ocean. It

has a good harbour, and is a favourite summer-resort. Pop. 2800.

Beaufort, HENRY, Cardinal, born in 1377, was a natural son of John of Gaunt, Duke of Lancaster, by Catherine, widow of Sir Hugh Swynford, and was thus half-brother to Henry IV. His parents were married in 1396, and their children were legitimated next year by Richard II. He studied at Oxford and at Aix-la-Chapelle, was consecrated Bishop of Lincoln in 1398, and in 1405 succeeded William of Wykeham in the see of Winchester. He thrice filled the office of chancellor, and was involved in all the most important political movements of his times. At the Council of Constance (1417) he voted for the election of Pope Martin V., by whom in 1426 he was made a cardinal. He strongly opposed Henry V.'s proposition to levy a new impost on the clergy, in order to raise money for carrying on the war against France; but nevertheless he lent the monarch, out of his own private purse, £28,000—in 1416 £14,000, and as much in 1421—an almost incredibly large sum in those days, and one which justifies the belief that he was the wealthiest subject of his time in all England. In 1427 the pope sent him as legate into Germany, there to organise a crusade against the Hussites. This undertaking failed; and the cardinal, having expended, in levying an English army against France, the moneys granted from Rome for other purposes, fell under papal displeasure. In 1431 he conducted the young king, Henry VI., to France to be crowned in Paris as king of France and England. Here, too, he endeavoured, but vainly, to reconcile the Duke of Bedford with the offended Duke of Burgundy. He died at Winchester in 1447, within seven weeks of the murder of his great political rival, the Duke of Gloucester. He ruled England when self-government was first being tried successfully, and was enlightened in his foreign policy; after his death all went wrong. He and his official Lyndwood held the pope to be above the council. See a work on him by L. B. Radford (1908).

Beaufort, JANE, Queen of Scotland, was a daughter of John Beaufort, first Earl of Somerset and Marquess of Dorset, son of John of Gaunt and Catherine Swynford, and was therefore niece to the Cardinal. She married James I. of Scotland, and was wounded in defending him against his murderers, whom she punished with ferocity. As guardian of her son James II. she came into conflict with Crichton and Livingston, and married Sir James Stewart of Lorne. She died in 1445. See JAMES I., JAMES II.

Beaufort Scale. See WINDS.

Beaufort West, a town of the Cape Province, South Africa, stands near the foot of the Nieuwveld Mountains, 339 miles by rail NW. of Capetown, and is the largest town (pop. 6000 in 1921) in this part of the Karroo. Its staple industries depend on the wool produced in the district, throughout which, on account of scanty rainfall, agriculture is possible only with ample irrigation.

Beaugency, an ancient town of France, in the department of Loiret, on the right bank of the Loire, 16 miles SW. of Orleans by rail. It was successively in the hands of the Huns, Saxons, Normans, and English; and it sustained great damage during the religious wars of the 16th century. Here the French army under General Chanzy was severely defeated in a series of desperate struggles, 7th to 10th December 1870, by the German force under the Grand-duke of Mecklenburg. Pop. 3000.

Beauharnais, ALEXANDRE, VICOMTE DE, born in 1760 of an ancient French family in the

island of Martinique; served, under Rochambeau, in the American War of Independence; and in 1789 eagerly embraced the French Revolution, voting, on the night of 4th August, for the abolition of privileges and the political equality of all citizens. As a reward for his constancy to the cause of liberty he was named Secretary of the National Assembly and subsequently member of the military committee, but largely forfeited his popularity by venturing to praise and defend the conduct of General Bouillé in his sanguinary suppression of the insurrection at Nancy. The flippant manner in which he received the news of the flight of Louis XVI. was eminently characteristic of the man. He merely rose and said to the Assembly: 'Gentlemen, the king has just gone off; let us pass to the order of the day.' In 1793 he declined the office of Minister of War, and tendered his resignation as general of the Army of the Rhine, because it had been determined to exclude the nobility from the service. During the Reign of Terror his enemies revived the report that he had participated in the surrender of Mainz, because he had remained idle with his troops for 15 days. In consequence of this accusation he was brought to Paris, tried, and sentenced to death by the revolutionary tribunal. He submitted to his fate with firmness, and died on the scaffold, 23d July 1794. In 1779 he had married Josephine (q.v.), afterwards wife of Napoleon, and his daughter Hortense in 1802 married Napoleon's brother Louis, so that he was the grandfather of Napoleon III. See BONAPARTE, and Miss Taylor's *Queen Hortense and her Friends* (1907).

Beauharnais, EUGÈNE DE, son of the preceding, was born in 1781, and after his mother Josephine's marriage (1796) with Napoleon, accompanied him to Italy and Egypt. He rapidly rose to the highest military rank, and in 1805 was made a prince of France and viceroy of Italy. In 1806 he married the Princess Amelia Augusta of Bavaria, and not long afterwards was created Prince of Venice, and declared by Napoleon his adopted son, and heir of the kingdom of Italy. Although his political power was much limited, he conducted himself in Italy with great prudence, energy, and moderation, and throughout his life maintained an honourable and virtuous character. His military talents were great, and were displayed particularly in the Italian campaigns, in the wars against Austria, and in the retreat from Moscow, in which he divided with Ney the honour of saving the French army from total destruction. The victory of Lützen was decided by his conduct. Napoleon sent him from Dresden to Italy, which he ably defended, even after Austria had joined the coalition, and Murat had deserted the cause of the French Empire. In the Hundred Days he took no part; and in the Treaty of Fontainebleau and Congress of Vienna he was allowed to retain his possessions in the March of Ancona; and large sums were granted to him in compensation for his other Italian possessions, with which he purchased the landgraviate of Leuchtenberg and principality of Eichstadt, taking his place as Duke of Leuchtenberg among the nobles of Bavaria. He died at Munich on the 21st February 1824. See the Lives by Aubriet (1825), Baudoucourt (1827), Montagu (1913), and his *Mémoires et Correspondance*, by Du Casse (10 vols. 1858-60).—His second son, MAX EUGÈNE JOSEPH NAPOLEON (1817-52), who in 1835 succeeded his elder brother as Duke of Leuchtenberg, married a daughter of the Emperor Nicholas of Russia; and since 1852 his descendants have borne the name of Romanowski, and ranked among the members of the late Russian imperial family.

Beaujolais, a subdivision of the old province

of Lyonnais, France, which now forms the northern part of the department of Rhône, and a small part of Loire. Its fine vineyards yield the wine called Beaujolais, of which large quantities are exported. Beaujeu was the capital. It formed at first a separate barony, came into the hands of the Bourbons in 1400, was afterwards united to the crown by Francis I., and next passed into the hands of a nephew of the Constable de Bourbon. It came by marriage to the House of Orleans in 1826, with whom it remained until the Revolution.

Beaulieu (pronounced *Bewley*), a village of Hampshire, at the head of a creek, on the verge of the New Forest, 6 miles NE. of Lymington. A Cistercian abbey was founded here by King John in 1204.

Beaully (pronounced *Bewley*), a village, 10 miles W. of Inverness, with remains of a priory founded in 1232. Beaully Firth (7 by 2 miles) is the upper basin of the Moray Firth, and receives the river Beaully, winding 10 miles north-eastward.

Beaumarchais, DE, the name assumed by PIERRE AUGUSTIN CARON, next to Molière the greatest French comic dramatist. Born in Paris, 24th January 1732, son of a watchmaker, he was brought up to his father's trade, and at twenty-one invented a new escapement for watches, which was pirated by a rival. The vigour with which he assailed him soon brought him into notice at court, where his handsome figure and fine address quickly procured him advancement. He was engaged to teach the harp to the daughters of Louis XV., and ere long the wealthy widow of a court official married him, whereupon he assumed the title by which he was known thenceforward. Duverney, a rich banker of Paris, also befriended him substantially and helped him to some business speculations which realised a handsome fortune, ere long largely increased by another prudent marriage with a wealthy widow. His first plays, *Eugénie* (1767) and *Les Deux Amis* (1770), had but a moderate success. The death of his benefactor Duverney in 1770 now involved the versatile but hitherto unpopular upstart in a long lawsuit with his heir, Count Lablache, in the course of which he became the idol of the populace, as the supposed champion of public rights against the corrupt tribunals of the old régime. In the first trial Beaumarchais gained his cause, but an appeal to the *parlement* formed by the chancellor Maupeou was decided against him, principally through the exertions of Gozman, one of its members. Beaumarchais carried his appeal to the public by publishing his famous *Mémoires du Sieur Beaumarchais par lui-même* (1774-78; new ed. by Sainte-Beuve, 1873), a work which united the bitterest satire with the sharpest logic, and gained for him a reputation that made even Voltaire uneasy. It fitted in with the popular feeling of dissatisfaction with existing institutions, and did much to help on the Revolution. The same brilliant satire burns in his two famous comedies, *Le Barbier de Séville, ou la Précaution Inutile* (1775), and *La Folle Journée, ou le Mariage de Figaro* (1784). The latter had a most unprecedented success, and indeed for brilliant wit it may almost be put beside the masterpieces of Molière. Figaro was a permanently enduring creation worthy to be compared with the hardly more famous Tartuffe. These plays are still popular acting plays in France, but in England are chiefly known through the adaptation of them in the grand operas of Mozart and Rossini. The later works of Beaumarchais are hardly worthy of his genius. By furnishing the American colonists with arms and money he did much to make the revolution successful. Two later law-suits cost him

his popularity, and in the troubles of the French revolution the not over-scrupulous author lost his fortune, and, suspected of an attempt to sell arms in Holland to the enemies of the republic, had even to flee from Paris for his life. In *Mes Six Époques* (1793) he has given us an account of his sufferings during that period. In his last years he became quite deaf; he died on the 19th May 1799.

See the Lives and monographs by Loménie (trans. 1857), Lindau (1875), Lintilhac (1887), and Hallays (1897); Marsan, *Beaumarchais et les Affaires d'Amérique* (1919); Elizabeth S. Kite, *Beaumarchais and the War of American Independence* (1920).

Beaumaris, a seaport and chief town of Anglesey, North Wales, is situated on the west side of the picturesque bay of Beaumaris, near the north entrance to the Menai Strait, 3 miles N. of Bangor, and 239 miles NW. of London. It has the ivy-covered remains of a castle (now preserved as an ancient monument) erected by Edward I., and a free grammar-school, and is a favourite sea-bathing resort. The bay is a safe anchorage in stormy weather. Up till 1885 Beaumaris united with Amlwch, Holyhead, and Llangefni in sending one member to parliament. The trade is inconsiderable, but there are some exports of copper and other ores, slates, marble, &c. Pop. 1800.

Beaumont, a city of Texas, on the Neches River, 84 miles E. by N. of Houston. Its excellent communications by rail and water, and the neighbourhood of forests and ricefields, had already made it a great centre of the lumber and rice trade, when rich finds of oil raised its population from 9427 in 1900 to 20,640 in 1910 and 40,422 in 1920.

Beaumont, ÉON DE. See ÉON DE BEAUMONT.

Beaumont, FRANCIS, and **Fletcher**, JOHN, a pair of the greater dramatists of the Elizabethan age, whose joint work is the result of the most famous of literary partnerships. Beaumont was the younger of the two by about five years, but he died nine years earlier than his friend. He was the third son of Sir Francis Beaumont, one of the justices of the Common Pleas, and was born at Gracedieu, in Leicestershire, in 1584. He was admitted in 1597 as a gentleman-commoner to Broadgate Hall, Oxford (now Pembroke College), and in 1600 to the Inner Temple. Two years thereafter he published *Salmacis* and *Hermaphroditus*, an expansion of Ovid's version of the story. Ere long he became an intimate friend of Ben Jonson and the other men of genius who assembled at the Mermaid Tavern, and here no doubt he met the poet with whom he was to form so memorable a friendship. John Fletcher was born at Rye in Sussex, in December 1579. His father was that Dean of Peterborough who disturbed the last moments of Mary Stuart with his ill-timed exhortation, and afterwards as Bishop of London, died either of chagrin at the queen's displeasure on account of his second marriage, or of the immoderate use of tobacco. The boy entered Bene't (now Corpus) College, Cambridge, at twelve, and found himself at seventeen in poverty on his father's death. We know nothing of him until 1607, when he produced the *Woman Hater*. The intimacy which now commenced was one of singular warmth, even for that age when friendships were of a more romantic cast than at present. The two lived in the same house, and had clothe and cloak and everything in common. Aubrey ascribes the 'deariness of friendship between them' to a 'wonderfull consimilitude of phansy.' Beaumont married in 1613, but died 6th March 1616. Fletcher wrote on until his death, in his last four years producing no less than eleven new plays. He died in August 1625.

Till well on in the 19th century critics failed to

distinguish differences of style between the two dramatists; but, applying metrical and other tests, modern scholarship confidently—and often convincingly—awards to each his share in the joint works. Of over fifty tragedies and comedies indiscriminately attributed to Beaumont and Fletcher, about a third are now generally assigned to Fletcher alone; another third to Fletcher and Massinger (after Beaumont's death); one sixth to Beaumont and Fletcher, and the rest to Fletcher with other collaborators (Shakespeare, Jonson, Field, &c.).

Modern opinion on the authorship of the various plays is fairly summarised by Mr G. C. Macaulay thus. The *Woman Hater* (1607) and a *Masque* (1613) are by Beaumont alone. Besides *The Knight of the Burning Pestle* (mostly Beaumont's), *The Scornful Lady*, *The Coxcomb*, *Philaster*, *The Maid's Tragedy*, *A King and No King*, *Cupid's Revenge*, and *Four Plays in One* are by Beaumont and Fletcher—all seemingly acted between 1609 and 1612. Of Fletcher's unaided works (sixteen or seventeen) most noteworthy are: *The Faithful Shepherdess*, a pastoral drama of high poetic beauty, though a stage failure (? 1609); *Valentinian* and—perhaps with Field—*Bonduca*, tragedies (by 1614); *The Loyal Subject* (1618) and *Humorous Lieutenant* (1619), tragi-comedies; *Monsieur Thomas*, *The Pilgrim* (1621), *The Wildgoose Chase*, *Rule a Wife and Have a Wife*, *The Chances* (acted 1625 or 1626), comedies. Massinger has belatedly been credited with a hand in the framing and writing of over a dozen plays, including *The Bloody Brother* (or *Rollo, Duke of Normandy*), *Thierry and Theodoret* (1617), *Sir John Van Olden Barnavelt* (1619), *The False One*, historical tragedies; *Little French Lawyer* (c. 1619), *Beggar's Bush*, *Spanish Curate*, and *Elder Brother* (staged after Fletcher's death), comedies.

Beaumont's verses are more severe and regular in form than those of Fletcher, whose versification has many peculiar features which make his verse distinguishable from that of his contemporary dramatists. The chief of these is the frequency of double or feminine endings, in which he may be safely said to exceed any other writer of our old drama. Ward observed that the double-endings, particularly as used by Fletcher in combination with the practice of stopping the sense at the end of the verse, give so peculiar a cadence to the lines, and constitute a manner of versification from which when once adopted a poet is so unlikely incidentally to diverge, that their frequent employment in scenes of joint plays and their sparse employment in other scenes, may be fairly regarded as favouring the antecedent supposition of the presence or absence of Fletcher's hand. At the same time, too much may well be made of such mechanical tests, and it may be permitted to leave a problem that so acute a critic as the late Mr W. B. Donne regarded as insoluble in the pious uncertainty of the stationer's address to the courteous reader in the first folio edition of 1647 (the earliest, though that of 1679 was the first complete edition): 'It was once in my thoughts to have printed Mr Fletcher's works by themselves, because single and alone he would make a just volume; but since never parted while they lived, I conceived it not equitable to separate their ashes.' Fletcher undoubtedly had a share in Shakespeare's *Henry VIII*. The touch of Shakespeare is felt with considerable certainty in *The Two Noble Kinsmen*. There is a tone of music and a tread of thunder in some of the passages, to which no parallel can be found in any of the companion dramas. Only three plays were, during Fletcher's lifetime, published as joint productions. Two of these—*Philaster* and *The Maid's Tragedy*—are (not to reckon the great passages in *The Two Noble Kinsmen*)

the glory of the collection. The question has been often discussed, why these plays are called by the name of Beaumont and Fletcher, thus giving precedence to the younger and less voluminous writer. Dyce's opinion was that of the three plays published as joint productions during Fletcher's life, Beaumont either had the greater share, or that, through feelings of natural courtesy, Fletcher placed the name of his deceased associate before his own, and that future editors naturally followed the arrangement which they found to their hand. From all that can be gathered, it would appear that Beaumont possessed the deeper and more thoughtful genius; Fletcher the gayer and more idyllic. There is a strength as of granite rock in *The Maid's Tragedy*; there is a glad exuberant music, and a May-morning light and freshness in *The Faithful Shepherdess*, which Milton did not disdain to accept as a model in the lyrical portions of *Comus*, and of which the *Endymion* of Keats is but an echo. The plays of Beaumont and Fletcher never sound the deep sea of passion; they disport themselves, dolphin-like, on its surface. They are poets first and dramatists after; and indeed display but little power of serious and consistent characterisation, while they are much too fond of unnatural and violent situations. Morally, little can be said in their praise. Even that most delightful pastoral *The Faithful Shepherdess* is marred by deformities that interfere with its harmonious beauty. 'A spot,' says Charles Lamb, 'is on the face of this Diana. Nothing short of infatuation could have driven Fletcher upon mixing with this "blessedness" such an ugly deformity as Cloe, the wanton shepherdess!'

Weber's edition (1812) and Dyce's (11 vols. 1843-46) were superseded by Bullen's edition (1904 *et seq.*, incomplete) and the edition by Glover and Waller (10 vols. 1905-12). Mr St Loe Strachey gave the best plays in the 'Mermaid' edition (2 vols. 1904). See Sir A. W. Ward's *History of English Dramatic Literature* (2 vols. 1875); G. C. Macaulay's *Francois Beaumont* (1883); C. M. Gayley, *Francois Beaumont* (1914); Swinburne, *Contemporaries of Shakespeare* (1919).

Beaumont, SIR GEORGE HOWLAND, landscape painter and patron of art and artists, was born at Stonehall, Dunmow, Essex, 6th November 1753, and studied at Eton and New College, Oxford. He was an intimate friend of Sir Joshua Reynolds; entertained Wordsworth at his house of Coleorton, in Leicestershire, where Scott, Rogers, and Byron met; befriended Coleridge and the painters Wilkie, Haydon, and Landseer; and presented his valuable collection of pictures to the National Gallery. He died 7th February 1827.

Beaumont, JEAN BAPTISTE ÉLIE DE, born in 1793 at Canon, in Calvados, taught geology in the Ecole des Mines and Collège de France, was elected to the Academy in 1835, and became in 1856 its perpetual secretary. He died 22d September 1874. With Dufrénoy he prepared a great geological map of France (1840; 2d ed. 1855). See MOUNTAINS.

Beaumont, SIR JOHN, baronet (1582-1628), elder brother of the dramatist. Grosart edited his *Bosworth Field* and other poems (1869).

Beaumontague is a composition of iron borings, brinstone, pitch, sal-ammoniac, rosin, and beeswax, which is used to fill up cracks and flaws in an iron casting, to give an appearance of solidity.

Beaune, a well-built town in the French department Côte d'Or, 23 miles SSW. of Dijon by rail, with a fine parish church, Notre Dame (13th century); a splendid hospital, founded in 1443 by Nicholas Rollin; and a bronze statue (1849) of Monge the mathematician. It manufactures serges, woollen cloth, and cutlery, and is a chief seat of the Burgundy wine trade, Beaune giving name to

one of the best Burgundies. During the Franco-German war in 1870 the town was several times occupied by the Germans. Pop. 10,000.

Beaune, FLORIMOND DE, a mathematician and friend of Descartes, born in 1601 at Blois, in France, served as a soldier, and died at his native place in 1652. His labours and discoveries contributed greatly to the improvement of the modern analytical geometry first introduced by Descartes. He is well known through 'Beaune's Problem,' solved with the help of the integral calculus by Jean Bernoulli in 1693, which turns on the determination of the nature of a curved line from a property of its tangent.

Beauregard, PIERRE GUSTAVE TOUTANT, Confederate general, was born in 1818, near New Orleans, graduated at West Point in 1838, served with distinction in the Mexican War, and after its close superintended the engineering works on the Lower Mississippi and the Gulf of Mexico. He joined the secession with his native state, and was appointed by the Confederate government to the command at Charleston, S.C., where, April 12, 1861, he commenced the war by the bombardment of Fort Sumter. He was virtually in command at the first battle of Bull Run, July 21, 1861; and sent to the west in the spring of 1862 as second to General A. S. Johnston, he succeeded to the command when the latter was killed in the first day's battle of Shiloh or Pittsburg Landing. Defeated on the second day's fighting, he retreated to Corinth, Miss., where he reorganised his division; but on the approach of the Union troops he evacuated the place, and was superseded by General Bragg. After a period of inactivity he was placed (1864) in command of the military division of the west, but failed to check Sherman's march to the sea. After the war, he was president of a railway, and manager of the Louisiana State Lottery. He died 21st February 1893.

Beausobre, ISAAC DE, Huguenot preacher and writer, was born at Niort, in Poitou, in 1659, studied theology at Saumur, and after his ordination had charge of a church at Châtillon-sur-Indre. The revocation of the Edict of Nantes, in 1685, obliged him to flee to Holland. In 1694 he went to Berlin, became chaplain of a French Protestant church there, and councillor of the royal consistory. Among his works were an *Essai critique de l'Histoire de Manichéisme et du Manichéisme* (1734-9), which Gibbon characterises as a rich treasury of facts and opinions; and along with M. Lenfant, a translation of the New Testament, with notes. He was a chief contributor to the voluminous *Bibliothèque Allemande*. He died at Berlin in 1738.

Beauty. See *ÆSTHETICS*, ART.

Beauvais, a town of France, capital of the department Oise, situated in the valley of the Thérain, 55 miles NNW. of Paris. Among several fine buildings the most noteworthy is the unfinished cathedral, begun in 1225, the choir of which, 153 feet high, is the loftiest as well as one of the finest specimens of Gothic in France. The industries include the weaving of Gobelin tapestries (since 1664), and the manufacture of cotton, woollen cloths, shawls, carpets, and toys. Population, 20,000. Beauvais was known by the Romans as *Cæsaromagus*, afterwards as *Bellovacum*. In 1472 it was besieged by Charles the Bold of Burgundy, with an army of 80,000 men, when the women of Beauvais, under the leadership of the heroine Jeanne Hachette, displayed remarkable valour. The standard which the Burgundians had planted on the wall was torn down by Jeanne, and borne off by her in triumph. The banner is borne every year by young girls in a procession, and a statue of Jeanne was erected in 1851.

Beaver (*Castor*), a familiar rodent mammal, allied to squirrels and marmots, and represented by a single widely distributed species (*Castor fiber* or *canadensis*). It is widely known for its aquatic habit, its sagacious architectural devices, its glossy fur, and its fatty castoreum glands.

Form and Structure.—The beaver is usually about 2½ feet in length, and is thus hardly surpassed by any other rodent except the Capybara (q.v.). It stands rather under a foot in height, and the broad, flat, scaly tail is about 10 inches long. The body is plump, the back arched, the neck thick, the hind-feet webbed, and all the digits clawed. The strong wrist has an accessory bone. The fur varies considerably in colour, but is usually reddish-brown above, and lighter or grayish below. The short head runs out into a naked muzzle; the external ears are short and scaly, and admit of being folded, so as almost to shut the opening; the eyes are small; and the nostrils closable. The skull is massive, with marked ridges for fixing the muscles which work the jaws, and both size and ridges increase throughout life. The two front teeth on either jaw are like those of other rodents, wearing away more rapidly behind so as to leave a sharp enamelled chisel edge. They have a bright orange colour. They grow as usual from persisting pulps, so that what is worn away in gnawing is continually being replaced at the root. The four grinding teeth on each side of each jaw are nearly equal to one another, and exhibit two or three infoldings of the enamel coating. The stomach has near its commencement a peculiar glandular structure; the external relations of anal and urinogenital apertures resemble those of marsupials; and the male bears on its groin a pair of glands which secrete a substance known as *Castoreum*.

Distribution.—The beaver, though represented only by a single species, is widely distributed in the northern parts of both eastern and western hemispheres. It is rapidly disappearing from countries where it previously flourished, being now, for instance, extinct in Britain, and apparently also in Scandinavia. An attempt has been made to reintroduce it in Bute. Isolated colonies of beavers are still to be seen where they have been protected from molestation on the Elbe and a few other rivers in Germany and Austria; but they can hardly be said to be really at home in Europe except in Russia and Poland, and 'especially on the streams of the Ural Mountains, and those emptying into the Caspian Sea.' They are also abundant in Siberia. The American beaver, which is probably only a variety, and not a distinct species, is found to the west of the Mississippi, between Alaska and Mexico, and more sparsely to the east of the same river, to the south of the Great Lakes, in the Maine and Adirondack wildernesses, and yet more sparsely southward to Alabama and Mississippi. They are also frequent in some parts of Virginia and Pennsylvania (see Heilprin, *Distribution of Animals*, International Science Series). Several extinct species of beaver have been dug up from Miocene and Pliocene strata. *Castoroides ohioensis* was an allied giant rodent about as big as a black bear. Another large extinct rodent, which Owen described under the title 'Trogotherium,' is regarded by some as a giant beaver.

Habits.—Beavers are well known to be aquatic animals, and are never found far away from river or lake. Their webbed hind-feet make them capital swimmers. They also dive well though noisily, and can remain two minutes under water. They feed mainly on the bark of trees, such as willows, magnolias, poplars, and birches, but also on the roots of the water-lily and other plants, and

on their inland excursions during the warm season on fruits, corn, and the like. They often sit on their hind-feet and tail, eating with their fore-paws like squirrels. They are, however, pre-eminently bark-eaters, and large quantities of wood are stowed up in the autumn for winter use. When the streams are frozen, they may remain for as long as a fortnight comfortably provided with supplies within their burrows. Most of the beavers' active life is during the night, except when floods force them to abandon their homes. They may be readily tamed, but cannot of course be kept in wooden houses. They may be seen in the London Zoological Gardens, and occasionally in aquariums.

Family-life.—Beavers are social animals; a family of about half a dozen is frequently found within a single house, and where food is abundant and the locality secluded, a large number of families occur congregated in a community. The young beavers leave the parent house in the summer of their third year, find mates for themselves, and establish new homesteads. When increase of population brings about difficulties of subsistence, a migration takes place, some going up and others down the stream. The old houses are never left vacant, however, but are simply transferred by the emigrants to some related new couple. Isolated males or terriers, apparently expelled from a colony for laziness or misbehaviour, are often found living alone.

Homes.—The simplest beaver home is merely a burrow, and when their tenure seems insecure, as in populous countries, the beavers may remain contented with this mode of life. These burrows open outwards under the water, and are thus effectively concealed. Mr L. H. Morgan, in his work on the American beaver, regards the burrow as the primitive and normal residence from which 'in the progress of experience, by a process of natural suggestion,' the more elaborate homes have been gradually evolved. Beaver architecture, as well as human, has had its history. Above the burrow a surface-pile of sticks is often found, perhaps to keep the snow loose enough overhead to admit air, and from these ventilating piles 'it is but a step to a lodge with its chamber above ground, and the previous burrow as an entrance from the water.' 'A burrow accidentally broken through at its upper end, and repaired with a covering of sticks and earth, would lead to a lodge above ground, and thus inaugurate a beaver-lodge out of a broken burrow.'

The Lodge.—However it may have arisen, the so-called beaver-lodge is a marvellous structure. Three distinct kinds can be distinguished in adaptation to different localities. The island-lodge is constructed on a small island in the pond or dam. It consists of a central chamber, with its floor a little above the level of the water, and with two entrances. One of these—the 'wood entrance'—is a straight incline rising from the water, and opening neatly into the floor of the hut. Up this the pieces of wood used for winter food are passed. The other approach—the 'beaver entrance'—is more abrupt in its descent to the water, and often tortuous in its course. Both approaches, which are often many feet in length, are neatly lined and finished off, especially where they open into the central chamber. The lodge itself is an oven-shaped house of sticks, grass, and moss, woven together and plastered with mud, increasing gradually in size with year after year of repair and elaboration. They are not only comfortable, but efficiently protective against beasts of prey. The room inside may measure 8 feet in diameter, and 2 or 3 feet in height. The floor is very comfortably carpeted with bark, grass, and wood-chips, and

there are sometimes special store-rooms adjoining. The entrances open into a specially deep moat surrounding the home, and as this is too deep to freeze readily, the inmates are not apt to be imprisoned even by very keen frost. Another kind

Beavers and Beaver-lodge.

of lodge is built on the bank of a stream or pond, either a short way back from the edge, or partly hanging over, with its front wall built up from the bottom of the pond. A third type—the so-called 'lake-lodges'—are built on the shelving shores of lakes, with a large part of the hut built out upon the water. The various forms of house, all apparently modifications of the primitive burrow, are of much interest, as illustrating the beaver's power of adapting its constructive powers to different local conditions. Mr Morgan also directs attention to the 'beaver-slides' or cuttings seen on the Upper Missouri, where the banks are too vertical to admit of the ordinary construction without some previous surface-work. In certain localities—for instance, in California—the animals have either relapsed from their ordinary architectural labours, or have never fully developed the constructive habit. Hunters often break into the lodges so as to drive the beavers into the holes or burrows.

Wood-cutting.—Some of the most interesting habits of beavers are connected with the way in which they procure and store their food-material. That they are bark-eaters has been already noticed, and it is an equally familiar fact that in order to procure this they cut down trees by gnawing a ring round the base. This they cut all round, but more towards the side nearest the water, so that the tree may fall as conveniently as possible. They can cut down a tree 10 inches or so in diameter. The smaller branches with more palatable bark are cut off in the same way, and cut into lengths convenient for transport and storage. The heavier pieces are ingeniously rolled along, often for a considerable distance, to the water-edge. Sometimes the tree is near enough to fall at once into the water, and is simply left till required, but such a convenient supply is soon exhausted. When a block has been rolled to the water-edge it is floated out to the lodge, and either anchored by means of brushwood stuck into the bottom of the pond, or sunk to the mouth of the 'wood entrance,' and conveyed up into the lodge. Barked branches from which the nutritive portion has been eaten away, may be further used, as already indicated, for building the lodges.

Beaver-dams.—Yet more marvellous are the dams

by which beavers widen the area and increase the depth of water round about their homes. These vary in structure according to the nature of the locality. They are either made of sticks and poles, with a slight embankment of earth, not enough to prevent the surplus water flowing freely through, or they are constructed more firmly and solidly of mud, brushwood, and stones, with a special outlet on the ridge for the discharge of the overflow. Though beavers do not hammer in poles, nor use their tails as trowels, they exhibit marvellous ingenuity in the construction of their dams. The stones and mud are cleverly carried by the fore-paws, the burden being pressed against the chest; the curvature of the dam is adjusted to the direction of the current; a constant level of water is secured by modification of the outlet sluice; the wear is continually remedied by fresh building; auxiliary dams are constructed to all appearance simply for the purpose of breaking the flow of water in the main dam, and so on. Some of these dams have prodigious dimensions. Mr Morgan describes one structure '1530 feet in length, of which 530 feet in two sections is artificial, and the remainder natural bank, but worked here and there where depressions on the ground required raising by artificial means.'

Canals.—Mr Morgan has also discovered and described the construction of waterways or canals, which the beavers dig between their ponds and the sources of timber-supply. When the trees near the water are exhausted, and when the uneven character of the ground makes the rolling of the logs a difficult task, canals are cut for convenience of transport. In certain cases the construction of a big dam may bring the water-edge quite near enough the trees, but this is not always so. The construction of canals becomes as necessary as it is marvellous. They may be hundreds of feet long, increasing in length as the trees are gradually cut away, and are usually about a yard or more in breadth, and 3 feet or so deep. Sometimes, however, the ground rises suddenly at a certain distance from the pond, so that a continuous canal becomes impossible. In such a case an engineer constructing a canal would make a 'lock.' This is exactly the solution of the difficulty which has been arrived at by beavers. Mr Morgan describes a case where three water-collecting crescent-shaped dams have been made, at three successive sudden ascents of the ground, and the principle of locks ingeniously combined with that of collecting reservoirs. In another case the canal bifurcates at the foot of the woodland slope, and thus presents a maximum water-edge. Or again, these acute engineers have been observed to make a short-cut waterway across the ground inclosed in a loop of the river, so as to lessen considerably the distance of transport.

Geological Interest.—All this work of burrowing, timber-felling, dam-building, canal-cutting, carried on continuously by generation after generation of beavers, must in no inconsiderable way have affected the minuter features of a landscape. Agassiz has estimated the age of one of these beaver dams at a thousand years. As the result of beaver work, large tracts once covered with trees have become bare, and what was once dry meadow has been flooded with water. Acres of what once was forest land are represented now by peaty clearings, and still remain as 'beaver meadows' in countries from which the busy foresters have long since disappeared.

Practical Uses.—The beaver has for long been hunted for the sake of its fur, from which both hats and gloves were made. Chaucer speaks of a 'Flandrish bever hat' about 1386, and we have 'brown beaver gloves' in Dickens' *Sketches by Boz* (1836). * An act of the English parliament, in

1638, prohibiting the use of any other material for hat-making, contributed to the rapid diminution of the number of beavers in the parts of North America from which their skins were then obtained (see HAT). During a great part of the 18th and the earlier part of the 19th century, the number of beaver skins annually exported from America appears to have been not less than 200,000. It is now greatly diminished, but is still large. From very ancient times the secretion of the gland, on the groin of male beavers, has been valued on account of its curative properties. So far as the beavers are concerned, the strong-smelling substance is apparently subsidiary to sexual attraction. Hunters are said to utilise it as bait for their traps. The so-called castoreum contains oily and resinous substances, along with a crystallisable component known as castorine, once largely employed in medicine as a nervous stimulant. Mythical stories are told of the way in which beavers throw themselves on their backs when pursued by hunters, so as to expose the wished-for glands, with a hint that their lives might be spared; according to the credulous they may even bite off the glands and leave them as a ransom. The oily flesh is said also to be esteemed by the trappers. The fat tail is a special delicacy, and the animal being popularly regarded as a fish, may be eaten during Lent.

Intelligence.—Enough has been said to show that the habits and labours of beavers exhibit more marks of sagacity than can possibly be the result of instinct alone. For they do much more than follow a hard-and-fast path of orderly and purposeful action—they can adapt their actions to varying conditions in a manner which can only be described as rationally intelligent. The Indians go further, and invest the beaver with immortality.

See L. H. Morgan, *The American Beaver and his Works* (1868); Harbing, *British Animals Extinct within Historic Times* (1880); Romanes on *Animal Intelligence and on Mental Evolution in Animals* (1886); and Horace T. Martin's *Castorologia* (1892); E. Thompson Seton, *Life-histories of Northern Animals* (1910).

Beaver Dam, a city at the outlet of Beaver Lake, Wisconsin, U.S., 65 miles NW. of Milwaukee, in the centre of a fertile district, has flour-mills, cotton and woollen mills, iron-works, and machine-shops; pop. 8000.

Beaver Falls, a borough of Pennsylvania, U.S., near the junction of the Beaver River with the Ohio, 31 miles NW. of Pittsburg, in a region abounding in coal and natural gas, with manufactures of iron, steel, machinery, glass, and pottery; pop. 13,000.

Beaver Islands, a group of small islands in the south-east corner of Lake Michigan, 40 miles west of its outlet the Straits of Mackinac, with several lighthouses on them. Here the Mormons tried to make a settlement in 1846.

Beaver-rat. See HYDROMYS.

Beaver State. See OREGON.

Beaver-wood. See MAGNOLIA.

Bebeerine, or BEBERINE, is an alkaloid obtained from the greenheart bark or *bebeeru* of British Guiana, sometimes used as a substitute for quinine; but it is not so powerful in its action as a tonic and febrifuge, and has not therefore come into popular use. Bebeerine is always prescribed in the form of sulphate, a dark amorphous substance, obtained in thin translucent laminæ by spreading the syrup solution on sheets of glass, and allowing it to dry. See GREENHEART.

Bebek, a lovely bay on the European side of the Bosphorus, with a palace, known as the *Humayunabad*, and built in 1725. Here are an American school, and a college of the French order of Lazarists.

Bebel, FERDINAND AUGUST (1840–1913), social democrat, born at Cologne, came in 1860 to Leipzig, where four years later he established himself as a master turner. As an orator, writer, and member of the Reichstag he was an influential representative of Socialism, his popularity being only increased by his imprisonment more than once. He wrote much on the Socialist movement, on the peasants' war, on the status of women, on Sunday labour, and an autobiography (1910).

Bec Abbey, the ruins of which are at Bec-Hellouin, Normandy, 2½ miles from Brionne, was at the height of its fame as a great Benedictine monastery in the middle of the 11th century, when the famous Lanfranc was prior. His fame as a scholar had made it one of the most renowned seats of learning in Western Europe, students flocked thither from all parts, and gifts were bestowed upon it by the great men of Normandy. The great Anselm, entering it in 1060, was abbot from 1078 to 1093, when he succeeded Lanfranc in the see of Canterbury.

Beccafico (*Sylvia hortensis*, or *Curruca hortensis*), a little bird of the family of the Sylviadæ, or Warblers (q.v.), sometimes called the Petty-chaps, and sometimes the Garden Warbler, rather rare in Britain, but abundant in some of the more southern parts of Europe, and in great demand for the table in Italy, its flesh being regarded as of peculiar delicacy. It is a mere summer bird of passage, however, not only in Britain, but even in the south of Europe. The upper parts are mostly of a brown colour, the lower parts whitish. It is a bird of very pleasing song. Beccafico is an Italian name signifying 'fig-pecker,' and is sometimes extended to other birds of the same family used for the table.

Beccamoschino (Ital., 'fly-catcher'; *Sylvia casticola*), a little bird of the family of Warblers, found in Italy. It is remarkable for its nest, which resembles that of the tailor-birds, and is usually placed in a bush with long leaves, which are neatly sewed together with some kind of vegetable fibre so as to form roof and floor.

Beccaria, CESARE, MARCHESE DE BECCARIA-BONESANA, a political and philanthropic writer, was born at Milan, March 15, 1735 (or in 1738). His opinions were formed by study of the French encyclopædists and Montesquieu. His chief work was his *Dei Delitti e delle Pene* ('On Crimes and Punishments'), first published anonymously at Monaco in 1764, in which he argues against the severities and abuses of criminal law, especially capital punishment and torture. The work became extremely popular, and was translated into all the European languages. It was hailed with enthusiasm by the French school, and commentaries were published by Voltaire and Diderot. A translation of it, with a life of Beccaria, was published by J. A. Farren in 1880. It is marked by eloquence, sensibility, and lively power of imagination. Kant unfairly accuses the author of an affected humanity, though it must be admitted that the German philosopher has exposed the invalidity of some of the arguments brought forward. On the whole, however, the work of Beccaria is acknowledged to have done great good, and the subsequent reforms in the penal code of European nations have generally taken the direction he has pointed out. He was among the first to advocate the beneficial influence of education in lessening crime. Both his arguments and his popularity made him many enemies, but their malice was frustrated by the efforts of Count Firmian, the Austrian governor of Lombardy, a man of liberal and enlightened sentiments. In 1768 Beccaria was appointed professor of Political

Philosophy at Milan, and achieved great success as a lecturer. In 1791 he was made a member of the board for the reform of the judicial code, and had the triumph of seeing several of his abused suggestions adopted. He died of apoplexy, November 28, 1794.—GIACOMO BATTISTA BECCARIA (1716–81) from 1748 was professor of Physics at Turin, and did much to forward the science of electricity, though himself he made no important discovery.

Beccles, a Suffolk market-town, on the Waveney, 8 miles W. of Lowestoft. It has a fine church with a detached belfry, a good grammar-school, and large printing-works. Pop. 7000.

Bec-fin, the common French name for different species of birds of the family Sylviadæ, or Warblers (q.v.).

Bêche de Mer. See TREPANG.

Becher, JOHANN JOACHIM, chemist, was born at Spire in 1635. He acquired an extensive knowledge of medicine, physics, and chemistry, and became professor at Mainz. He subsequently lived at Vienna, Munich, Würzburg, Haarlem, and finally London, where he died in 1682. He was accused of charlatanism, but unquestionably he rendered important services to chemistry. His *Physica Subterranea* (1669) was the first attempt made to bring physics and chemistry into close relation. He began to construct a theory of chemistry, and investigated the process of combustion. In this and his other works (including *Institutiones Chymicæ*, 1662) lies the first germ of Stahl's phlogistic theory.

Bechuanaland, an extensive tract in South Africa, inhabited by the Bechuanas, extending from 28° S. lat. to the Zambesi, and from South-west Africa to the Transvaal and Matabeleland; besides, the Bechuanas also still occupy a portion of the Transvaal. The territory of Bechuanaland was declared to be within the British sphere in 1885; the portion to the south of the river Molopo, British Bechuanaland, was made into a crown colony in 1885, and in 1895 was incorporated with the Cape Colony; this has an area of 51,500 sq. m. (larger than England without Wales), and a population of about 100,000—20,000 being whites. The protectorate beyond has an area of 275,000 sq. m.; that is, it is almost as large as the Cape Province itself, and is administered by its own kings or chiefs, with the help of a resident commissioner at Mafeking in British Bechuanaland, representing the king of Britain. Of the native tribes the most important are the Bamangwato. Pop. 153,000.

Bechuanaland is a portion of an elevated plateau 4000 to 5000 feet above the level of the sea, and though so near the tropics, is suitable for the British race. In winter there are sharp frosts, and snow falls in some years. The rains fall in summer, and then only the rivers are full. It is an excellent country for cattle; sheep thrive in some parts, and there are extensive tracts available for corn-lands; but it is not a wheat country on account of the summer rains. Though apparently subject to droughts, it is not more so than the Cape Province, and the greater portion will be available for farming operations when the necessary dams have been constructed. There are extensive forests to the north-east, and to the west the Kalahari Desert, which only requires wells dug to make it habitable. Cattle-rearing and the production of mealies and Kafir corn are the chief industries; gold is mined. Diamonds have also been found. The railway connecting Cape Town with Rhodesia, &c., traverses British Bechuanaland and the protectorate.

Education is provided with government assistance in the schools of the London Missionary Society and the Dutch Reformed Church. The Bechuanas are a black race, possessing a language in common

with the Bantu (q.v.) races of South Africa, extending as far north as the equator. Their ancestors are said to have come from the north, and, progressing south-west, met the Hottentots from the Cape of Good Hope journeying north. The Bechuanas have divided up within modern times, and comprise the Bahurutse, Bamangwato, Bakwena, Bangwaketse, Barolongs, Batlapins, and Batlarsos. Each tribe has an animal as an emblem or heraldic sign, which it is said they hold in esteem (see TOTEMISM). They were from 1832 at enmity with the Matabele, and later the Transvaal Boers on one pretext or another endeavoured to occupy their country. During the native risings in 1878 the Bechuanas invaded Griqualand West, and were in turn subdued by British volunteers as far as the Molopo. When the British government withdrew from Bechuanaland in 1880, the natives, being helpless, were left to the mercy of the Boers of the Transvaal, whose harsh treatment in 1882 and 1883 led to the Bechuanaland expedition in 1884. At the beginning of the 19th century the Bechuanas were further in advance in civilisation than other nations of South Africa, and they are still ahead in this respect. All important matters are decided in the public assembly of the freemen of the town, but matters are previously arranged between the chief and headmen, the chiefs exercising real control only by personal influence and adroitness. The natives pay a hut-tax. The protectorate was early included in the South African Customs Union. The short-lived Boer republics of Stellaland, on the Transvaal frontier, with Vryburg for capital, and Goshen farther north (1882-84), were broken up by Sir Charles Warren's expedition of 1884.

See Mackenzie's *Austral Africa* (1887), and his *Life by W. D. Mackenzie* (1902); Hepburn's *Twenty Years in Kham's Country* (1895); Sir H. E. Johnston's *Colonisation of Africa* (1899); and books named at CAPE OF GOOD HOPE.

Beckenham, an urban district of Kent, adjoining the county of London; pop. 33,000.

Becker, KARL FERDINAND, German philologist, was born near Treves in 1775, and in 1815 settled as a physician at Offenbach. Here he educated his own children with such success that several families induced him to take charge of theirs, and thus his house was converted into an academy (1823), which he conducted till his death in 1849. He wrote an *Ausführliche Deutsche Grammatik* (1836-39), and several other valuable treatises on the German language.

Becker, KARL FERDINAND, a German musician, born at Leipzig in 1804, at the age of fourteen made his first public appearance as a pianist. In 1843 he was appointed professor of the Organ at the Leipzig Conservatorium. His compositions for the organ have much value, but he is best known as a writer on the history of music, and as an important contributor to German musical periodicals. His collection of *Chorals* (1831), and *Die Hausmusik* (1840), are highly valued. He died October 26, 1877.—See also BEKKER.

Becker, WILHELM ADOLF, born at Dresden in 1796, studied theology and philology at Leipzig, and became in 1842 professor of Archæology there. He died at Meissen, 30th September 1846. His lively fancy, aided by a thorough knowledge of the classic languages, enabled him to make a novel use of antiquity. In his *Charicles* (1840) he ventured to reproduce the social life of old Greece, and in his *Gallus* (1838) to give sketches of the Augustan age at Rome. His *Handbuch der Römischen Alterthümer* (1843-46) was, after his death, continued by Marquardt (vols. iii.-v. 1849-68).

Beckerath, HERMANN VON, a German politician, was born at Krefeld, Prussia, 13th December 1801. He made a considerable fortune as a banker, and in 1843 was elected representative of his native town in the provincial diet. Elected to the National Assembly at Frankfort in 1848, he was appointed minister of finance, and shortly after called to Berlin to construct a cabinet; but in this he failed. He was a resolute advocate for German unity. In 1858 he was again elected a member of the Prussian second chamber; but declined the honour on account of failing health. He devoted his later years to the affairs of his native town, where he died 12th May 1870. See *Life by Kopstadt* (Brunswick, 1874).

Becket, THOMAS, Archbishop of Canterbury, was born in London in 1118 of Norman parentage, his father being a wealthy merchant. That his mother was a love-lorn Saracen is a pretty but wholly baseless tradition. Educated at Merton Priory and in the London schools, he was trained in knightly exercises at Pevensey Castle, next studied theology at Paris, and then, on his father's failure in business, was clerk for three years in a lawyer's office. About 1142 he entered the household of Theobald, Archbishop of Canterbury, who sent him to study canonical jurisprudence at Bologna and Auxerre, heaped preferments on him, including the archdeaconry of Canterbury (1154), and employed him in several important missions. At the papal court in 1152 he had promoted the cause of Henry of Anjou against that of Stephen's son, Eustace; in 1155, the year after Henry's accession, he received the office of chancellor, and thus resuscitated the hopes of the English as the first Englishman born, since the Conquest, who had filled any high office. His duties as chancellor were numerous and burdensome, but he discharged them vigorously. So magnificently liberal was he in his hospitality, that Henry himself did not live in a manner more sumptuous. He fought like any knight in the war with Toulouse (1159), and would seem in everything to have regarded himself as a mere layman, though he held deacon's orders. The change, then, was all the more sudden when in 1162 he was created Archbishop of Canterbury, an office which, as it then involved the abbacy of the cathedral monastery, had never but twice before been held by any but a monk or canon-regular. He resigned the chancellorship, threw aside all his old courtly and luxurious habits, turned a rigid ascetic, showed his liberality only in charities, and in short became as zealous a servitor of the church as ever before of king or archbishop. He figured soon as a champion of her rights against all aggressions by the king and his courtiers, several nobles and other laymen being excommunicated for their alienation of church property. Henry II., who, like all the Norman kings, endeavoured to keep the clergy in subordination to the state, in 1164 convoked the nobility and clergy to a council at Clarendon (q.v.), where were adopted the so-called 'Constitutions,' or laws relative to the respective powers of church and state. To these, curtailing clerical immunities, the primate at first declared he would never consent; but afterwards, through the efforts of the nobles, some of the bishops, and, finally, of the pope himself, he was induced to give his unwilling approbation. Henry now began to perceive that Becket's notions and his own were utterly antagonistic, and clearly exhibited his hostility to the prelate, whereupon Becket tried to leave the country. For this offence Henry charged him with breach of allegiance, in a council held at Northampton, confiscated his goods, and sequestered the revenues of his see. A claim was also made on him for not less than 44,000 marks, as the balance due by him to the crown when he

ceased to be chancellor. Becket appealed to the pope, and next day leaving Northampton in disguise, escaped to France. He spent two years in retirement at the Cistercian abbey of Pontigny in Burgundy; and then, the pope seeming disposed to take up his cause, he went to Rome, and pleaded personally before his holiness, who reinstated him in the see of Canterbury. Becket now returned to France, and thence he wrote angry letters to the English bishops, threatening them with excommunication. Several efforts were made to reconcile him with Henry, which, however, proved futile; but at length in 1170 an agreement was patched up at Freteval, on the borders of Touraine. The result was that Becket returned to England, entering Canterbury amid the rejoicings of the people, who were unquestionably proud of him, and regarded him—whether wisely or not is another question—as a shield from the oppressions of the nobility. Fresh quarrels soon broke out; excommunications were renewed; and Henry at last exclaimed: 'Of the cowards that eat my bread, is there none will rid me of this turbulent priest?' Four knights—Fitzurse, Tracy, Brito, and Morville—overheard the hasty words; and, quitting Normandy by separate ways, on the evening of 29th December 1170 entered Canterbury cathedral, and slew the archbishop before the altar of St Benedict, in the north transept. Henry was compelled to make heavy concessions to avoid the ban of excommunication. The murderers, having repaired to Rome as penitents, were sent on a pilgrimage to Palestine; and, two years after his death, Becket was canonised, and the anniversary of his death set apart as the yearly festival of St Thomas of Canterbury. In 1220 his bones were raised from the grave in the crypt where they had been hastily buried two days after his murder, and were deposited in a splendid shrine in the Trinity Chapel, which for three centuries continued to be the object of one of the great pilgrimages of Christendom, and which still lives in English literature in connection with Chaucer's *Canterbury Tales*. At the Reformation, Henry VIII. despoiled the shrine, erased Becket's name from the calendar, and ordered his bones to be burnt and scattered to the winds. Becket was violent, impetuous, stubborn, resentful of injuries, but in his great quarrel we need not doubt that he believed himself to be standing for the laws of God against the wickedness of men. He died not so much for maintaining that churchmen should not plead or be tried in the king's courts, but only in the church courts, as because he refused to take off a sentence of excommunication at the command of the men who threatened, and took, his life; maintaining thus the freedom of the church as he and Hildebrand understood it. No canonisation was more popular, and miracles at his shrine abounded; the people sympathised with his defence of the church, but glorified him mainly for a brave stand against the tyranny of king and nobles. That the question of English against Norman entered into the case is probably quite unhistorical.

See Robertson and Shephard's *Materials for the History of Becket* (Rolls Series, 1875-85); Stanley's *Memorials of Canterbury*; Freeman's *Historical Essays*; Hook's *Archbishops of Canterbury*; Stubbs in the *Constitutional History*; J. B. Adams in vol. ii. of the *Poet. Hist. of England* (1905); Lives by Morris (1885), Hutton (1889, 1910, 1926), E. A. Abbott (1898), and R. H. Benson (1908).

Beckford, WILLIAM, born in Jamaica, 19th December 1709, and educated at Westminster, became member for the city of London (1753), and twice Lord Mayor. As such he showed himself a doughty Whig. A petition from the corporation of London, presented by him, March 1770, to George III., being treated as unconstitutional, he in May presented a firm and dignified remonstrance. The

king's answer being still curt and unconciliatory, Beckford, after asking leave to speak, proceeded to argue the point with the king. His daring, or a cold, cost him his life, for just four weeks later he died in London, 21st June 1770. There is a notable statue of him in Guildhall.

Beckford, WILLIAM, son of William Beckford (q.v.), was born at Fonthill, Wiltshire, 1st October 1760. On his father's death in 1770 he inherited an enormous property, consisting for the main part of Fonthill and of estates in Jamaica, and estimated at a million of money, upwards of £100,000 a year. Young Beckford evinced unusual intellectual precocity; for in his seventeenth year he composed a satirical essay, entitled *Biographical Memoirs of Extraordinary Painters*, in which he did not spare living artists, and assailed the cant of criticism with the polished weapon of wit. In 1777 he visited the Continent, and met Voltaire at Paris. Three years thereafter he started on a grand Continental tour, and spent twelve months in rambling through Flanders, Germany, and Italy, revisiting the last in 1782. In 1783 he married Lady Margaret Gordon, daughter of Charles, fourth Earl of Aboyne, and next year entered parliament for Wells. In 1787 *Vathek* appeared in French. Beckford asserts that he wrote it at twenty-two years of age, at a single sitting. 'It took me,' he says, 'three days and two nights of hard labour. I never took off my clothes the whole time. The severe application made me very ill.' Nevertheless it is proved that he worked at it for some months. An English version of *Vathek*, made from an unpublished manuscript, had been issued in 1786. Beckford professed not to know the translator (understood to have been Samuel Henley, D.D.), but thought his work well done. In 1787 Beckford sought distraction from the loss of his young wife, a year before, in a visit to Portugal. In 1790 he sat for Hindon; in 1794 he accepted the Chiltern Hundreds, and again left England. Revisiting Portugal, he purchased an estate near Cintra, and occupied for a time that 'paradise' which Byron commemorates in *Childe Harold*. He returned to England in 1796; and in 1801 the splendid furniture of Fonthill was sold by auction, and the next year his valuable collection of pictures was disposed of in London. These dispersions were no sooner made than he began a new collection of books, pictures, furniture, curiosities, and proceeded to erect a new building at Fonthill, the most prominent feature of which was a tower 278 feet high. Beckford resided at Fonthill till 1822, when in one of those strange vagaries of feeling of which his life was so full, he sold the estate and house, with all its rare and far-gathered contents, to Colonel Farquhar for £330,000. Three years later the great tower, which had been raised on an insecure foundation, came to the ground. On the sale of Fonthill, Beckford removed to Bath, and immediately proceeded to erect another lofty tower. While residing there, he did not mingle in Bath society, and the most improbable stories concerning the rich and morose genius in their neighbourhood were circulated among the citizens. During all his life, Beckford was a hard-working student, devoured by a passion for books. Some of his purchases were perfectly imperial in their way. He bought Gibbon's library at Lausanne, to amuse himself when he happened to be in that neighbourhood. He went there; read in the fierce way that he wrote, three days and two nights at a sitting; grew weary of his purchase; and handed it over to his physician, Dr Scholl. Up till 1834 he had published nothing since *Vathek*, but in that year the literary silence of half a century was broken by the appearance of a series of letters, entitled *Italy, with Sketches of Spain and Portugal*, in two volumes. In the same year he republished

his *Memoirs of Extraordinary Painters*; and in 1835 he issued another volume, entitled *Recollections of an Excursion to the Monasteries of Alcobaca and Batalha*, made in June 1794. From the period of this last publication till his death, which took place on the 2d of May 1844, he lived in the deepest retirement. Beckford, since the publication of his Arabian tale, has been a power in English literature. His wit, his sarcasm, his power of graphic description, may be seen in his journal and letters; and his higher faculties of imaginative conception reign in the passages that shadow forth in gloom and glory the 'Hall of Eblis.' His library was sold by his great-grandson, the twelfth Duke of Hamilton, in 1882-83.

See the reprint of *Vathek* by Mallarmé (Paris, 1876), and the English edition by Garnett (1893); the *Life* by Cyrus Redding (1858); Whibley in *The Paganry of Life* (1900); the *Life and Letters* of Beckford by Lewis Melville (1910); and *The Episodes of Vathek*, three tales designed for the original edition by Beckford, but first published by Marzials and Melville in 1912.

Beckmann, JOHANN, born in 1739 in Hanover, was in 1766 appointed professor of Philosophy, and in 1770 of Political Economy, at Göttingen, where he died, February 4, 1811. In Germany he was the first scientific writer on agriculture. In England he is known by his *History of Inventions* (5 vols. 1780-1805; Eng. trans. 1814).

Beckwith, J. C. See WALDENSES.

Beckx, PETER JOHN, general of the Jesuits, was born at Sichem, in Belgium, February 8, 1795. He was early employed on various delicate missions, and was for many years confessor to the Duke of Anhalt-Köthen. In 1847 he was appointed procurator for the province of Austria, and on the expulsion of the society in 1848, returned to Belgium, and became rector of the college at Louvain. He was named provincial of Austria in 1852, and as head of his order from 1853, displayed an ability and tact that did much to advance the status of Jesuits in non-Catholic countries. He died at Rome, March 4, 1887.

Becquerel, ANTOINE CÉSAR, a distinguished French physicist, was born in 1788, at Châtillon-sur-Loing, in the department of Loiret. In 1808 he entered the French army as an officer of engineers, and served with distinction in Spain. On his return to France, he was appointed inspector of the *École Polytechnique*; was attached to the general staff of the army in 1814, but at the peace of 1815 retired from the service. His researches and discoveries were mainly in the fields of electricity and magnetism, and he may fairly be regarded as one of the creators of electro-chemistry. His labours in this branch of science opened to him in 1829 the doors of the Académie des Sciences. Among his works were the *Traité de l'Électricité et du Magnétisme* (7 vols. 1834-40); *Éléments d'Électrochimie* (1843); *Traité de Physique*; *Éléments de Physique terrestre et de Météorologie* (1847). He died on the 19th January 1878.—His son, **ALEXANDRE EDMOND**, also an eminent physicist, was born at Paris, 24th March 1820. He was decorated with the cross of the Legion of Honour in 1851; and was appointed professor of Physics in the *Conservatoire des Arts et Métiers*, in 1853. He died 13th May 1891. Besides his conjoint labours with his father, he made important researches on light, on phosphorescence, and on the conductivity and magnetic properties

of many substances.—His son, **ANTOINE HENRI** (1852-1908), was, even before he became professor at the *École Polytechnique*, recognised as one of the greatest physicists of his time. For the Becquerel Rays, see RADIUM.

Becse, a town of Yugoslavia, on the Theiss, and 45 miles S. of Szegedin; pop. 20,000.

Becskerek (NAGY), a town of Yugoslavia (till 1920 Hungary), on the Bega Canal, 45 miles SW. of Temesvár by rail; pop. 26,000.

Bed, an article of furniture made up of diverse materials on which persons rest and sleep. In ancient Palestine the bed seems to have been a simple kind of couch for reclining on during the day, and sleeping on at night, and readily removable from place to place, as is referred to in different parts of Scripture. About the heat of the day, Ishbosheth lay on his bed at noon (2 Sam. iv. 5). In receiving visitors, the king bowed himself upon the bed (1 Kings, i. 47). Jesus saith, 'Take up thy bed, and go unto thine house' (Matt. ix. 6). Yet, in these early times, beds or couches must, in some instances, have been highly ornamented: thus, 'I have decked my bed with coverings of tapestry, with carved works, with fine linen of Egypt' (Prov. vii. 16). In Persia, even at the present day, every person sleeps on a rug or piece of carpet laid on the floor, or commonly, during the summer, laid on the flat roof of a house. The pillows are similar to those used in Europe, but rather larger. It is the custom in India, on the other hand, to sleep on a bed or couch raised on four feet, called a *charpoy*. In hot climates few bed-clothes are used—there being in general only a single sheet employed; care is taken, however, to use mosquito-curtains, without which rest would be impracticable. See GNAT.

Greek and Roman Beds.—Representations of ancient Greek beds and sofas are found on painted vases and on some pieces of sculpture. These beds plainly differed but little from the simpler modern forms, while the sofas or couches were in shape, in some cases at least, exactly like those now used. We are enabled to form a more perfect idea of ancient Roman beds than can be got from pictures and bas-reliefs. In the wonderful collection of Pompeian bronzes forming part of the great museum at Naples, there are three of these beds. They are partly of bronze and partly of wood, but the wooden portions, which were originally of walnut, have been restored. Fig. 1 shows one of these. It will be seen that it is of the couch form, and very

Fig. 1.—Ancient Roman Bed found at Pompeii.

elegant. Its length is 7 feet 6 inches, its breadth 4 feet, and its height 1 foot 5 inches. In addition to these an ancient trundle or truckle-bed was found at Pompeii in 1868; it is shown in the museum under one of the three larger bedsteads. The Etruscan Museum in the Vatican at Rome contains an ancient bronze bed on six feet, with a bottom

formed of strips of metal exactly like those put on brass and iron beds at the present time, only they are placed diagonally in the old example. In short, the bedsteads we now prefer are more closely like those made in Italy 2000 years ago than any which have been in use during the long interval.

In Homer's time the bedding even of the richer classes consisted of a long fibred woollen blanket or mattress, and that of the poor of a simple hide spread on the hard floor. Linen sheets were used as covers. Later on, when Greece had introduced more luxurious habits from Asia, mattresses stuffed with wool or feathers became common, and of the same materials pillows were made. The Romans also stuffed their bedding with wool as well as with the soft down of geese, swans, and other birds. Their blankets and sheets were sometimes elaborately ornamented with patterns in colours either woven or embroidered.

Medieval and later Beds.—In Anglo-Saxon times, ordinary beds appear to have been plain wooden benches fixed in recesses, and having sometimes at least curtains in front—a kind of bed not yet entirely obsolete in Scotland. The bedding consisted, no doubt, of a large sack filled with straw, together with a sheet or sheets and coverlet. Mr T. Wright, in his *Homes of Other Days*, gives an illustration of a Saxon double bed of this nature with curtains. He also gives two woodcuts, after drawings in the Harleian manuscript, No. 603, of two Saxon bedsteads, box-shaped, with short corner pillars terminating in balls, and with the head end like that of a couch, but rather higher. The sides of one have thin balusters, but in the other they are plain. It is believed that these bedsteads were only used by persons of rank. The same author gives two figures of Norman beds. One of these so far resembles the isolated Saxon bedsteads, but it has a high panelled foot-board, and the sleeper lies on a slope with an oval disc at his head. The second illustration shows that the tent-bed with a top frame and side curtains was now in use. Louandre's *Les Arts Somptuaires* contains pictures of five beds, taken from a French illuminated manuscript of the 12th century. In these the bedstead takes the oblong form, with four short posts and balls, and much resembles the Anglo-Saxon ones referred to above. Except in the deep closed sides, and that in two of them the sleeper lies in a sloping position, these scarcely differ in general appearance from many plain modern beds; but at the top end there is a large flat disc, apparently swung on pivots, to enable the head to rest at any angle.

In the 13th century, beds were furnished much as at present, with a stuffed quilt, bolster, pillows, sheets, and coverlets. Among the rich, down was used; but feather-beds did not come into general use till the 15th century. All classes appear to have begun in the 13th century to take a pride in the appearance of the bed, while those who could furnished it with handsome curtains and coverings. In the 15th century the canopy, curtains, and other parts had together the general appearance of a modern half-tester or canopied bed; but the tester or back and the *celure* or roof were fixed to the wall and ceiling. In France especially from the 16th century till the Revolution the bed was a sumptuous object, and for state and ceremonial purposes it almost vied with the throne.

The large four-post bed was introduced in the 16th century, and continued in use till the middle of the 19th. Many of these beds, especially of the earlier time, were elaborately and beautifully carved, and furnished with rich hangings. Interesting examples of them are still preserved in old mansions and castles in England and on the Continent. The Great Bed of Ware, in Hertfordshire, now at Rye House, is of this age, and is one of the

curiosities of England. It is referred to in the *Twelfth Night* of Shakespeare. It measures 12 feet square (see fig. 2). A kind of camp-bed was also in use in the 16th century, which was carried about on journeys, and was frequently used in residences in place of a stationary bed. Some of

Fig 2. —The Great Bed of Ware.

these beds were luxuriously decorated. Francis I. made a present to Henry VIII. of England of a rich camp-bed of crimson velvet, embroidered with bands of leaves in gold, and with fruit of large and small pearls, which had cost him 13,500 livres.

Modern Beds.—The heavy four-post bed, which was so long characteristic of a well-furnished English bedroom, is becoming a thing of the past. The comparatively recent and scarcely less massive half-tester bed, which suited so well for the display of the more handsome furniture-woods, has also gone out of fashion. Even the much lighter four-post tent-bed, or its later form without the curtained roof, called the French bed, that was so recently to be seen in nearly every well-to-do working-man's house in Great Britain, is fast disappearing.

The modern aim in the construction of beds is simplicity of form, freedom from encircling curtains, hangings, and all impediments to ventilation and circulation of air. To discourage the harbouring of insect pests and the lodgment of noxious bacteria is also an important consideration. The use of metal bedsteads, iron and brass, undoubtedly most effectively conduces to these purposes, and that fact, combined with the moderate price at which they can be produced, has led to the predominant adoption of metal as against wood for beds.

Most serviceable and cheap beds are formed of strong iron angle-bars dovetailed together at the four corners, having tubular corner posts with head and foot pieces of rod-iron, all painted in enamel-colour. Formerly the bed-bottom was made of laced hoop-iron, which in use gradually sagged in the middle; but now there are numerous woven wire devices employed which form at once spring-mattresses and are not liable to sag. More costly bedsteads are made in lacquered brass in elaborate designs enriched with inlays of oxidised silver and coloured stones.

The headquarters of the British metal bedstead industry is Birmingham, but Wolverhampton, London, Manchester, and Glasgow also share in the now huge industry, finding its outlets not only in

the United Kingdom, but in all British colonies and dependencies and in foreign markets.

Bed Furnishings.—An entire bed equipment is composed of diverse elements. The bed proper is either a bag of linen 'tick' filled with soft loose material or an upholstered mattress. The contents of the linen bag may be downs, feathers, rag-flock, or oaten chaff; but such bag beds are not now nearly so much used as in earlier days when feather beds were almost universal in the houses of the well-to-do, and chaff beds were in Scotland the common equipment of rural households. Mattresses are now, however, generally preferred, and these are made up of hair, wool, and rag-flock. The most comfortable and luxurious mattresses are made with an under-structure of steel springs upholstered with a covering of hair. Bolsters and pillows for head-rests are filled with downs or feathers. Sheets, generally of linen, but sometimes of cotton or wool, cover the bed and its occupant. Warmth for the sleeper is provided by woollen blankets (sometimes with a down quilt added), and in the day-time the surface is overspread with a coverlet (*Fr. couvre-lit*).

In Continental countries the bed is generally fitted for the use of a single person, and though more spacious structures fitted for two—sometimes more—are commonly found in the United Kingdom, the more healthful single bed is increasing in favour.

The use of filthy materials in the filling of cheap beds and the stuffing of mattresses became so grave a menace to public health early this century that legislative action to abate the evil became necessary. Accordingly the 'Rag-flock Act' was in 1911 passed by the British parliament, the principal provision of which was to prohibit the sale and use of rag-flock for bedding, &c., which contains more than 30 parts of chlorine per 100,000 parts of flock. The act, though not very satisfactory, has had the beneficial effect of bringing the flock industry under the supervision of sanitary authorities throughout the country.

Mats and Pillows in Warm Countries.—In most parts of Africa, and the tropical and subtropical islands of the Pacific Ocean, it is a common custom

Fig. 3.—Various forms of Pillows:

a, pillow used by the natives of the Zambesi Delta; b, from Swaziland, South-east Africa; c, ancient wooden pillow from the Tombs of Thebes; d, Japanese lacquered wooden pillow with cushion; e, wooden pillow from Fiji Islands.

to sleep on mats of some vegetable fibre, but sometimes skins are used for this purpose. Many South American Indians sleep on hammocks suspended

from the roofs of tents or from trees. At least one form of the ancient Egyptian bedstead appears to have been like the one still common in that country, namely, a low frame formed of wicker-work of palm-sticks. Much more curious, however, is the pillow used in Egypt in ancient times, since it forms the type of many used at the present time in far-distant countries. These Egyptian pillows or head-rests were generally made of wood, but sometimes of alabaster or earthenware. Fig. 3, c, represents one of wood, from the Tombs of Thebes. The same kind of wooden pillow or support for the head is still found in Abyssinia, the delta of the Zambesi, and in that direction as far south as Swaziland. It is also used in the country around Lake Tanganyika, in Ashanti, and in other parts of Africa. Much the same form of head-rest is made in the Fiji Islands, in Tahiti, and in New Guinea; while in China and Japan we find a somewhat similar pillow of wood, lacquered it may be, with a small cylindrical cushion on the top (see fig. 3).

The word *bed* is probably from the Indo-Germanic root *bhōdh* ('dig'), and thus originally applied to a dug-out sleeping-place. *Bed* in gardening may go back directly to the notion of digging, or may be an extension of the ordinary use.

In geology *bed* is synonymous, or nearly so, with *Stratum* (q.v.); and see GEOLOGY, also the articles BALA BEDS, BEMBRIDGE BEDS, MAESTRICHT BEDS, PURBECK, EOCENE, &c.

See also articles BED-SORES, BED OF JUSTICE.

Bédarieux, a town of France, department of Hérault, situated on the river Orb, 27 miles NNW. of Béziers by rail; pop. 5000.

Bedawi. See BEDOUINS.

Bed-bug. See BUG.

Bedchamber, LORDS OF THE, or lords in waiting, officers in the British royal household, who wait in turn upon the sovereign's person. They are under the groom of the stole, who attends the king only on state occasions. There are also grooms of the bedchamber, or grooms in waiting, who take their turns of attendance. These offices in the reign of a queen are performed by ladies. Corresponding to the groom of the stole is the mistress of the robes, and to the lords and grooms in waiting are ladies of the bedchamber and bed-chamber women. These offices are objects of high ambition, from the access they give to the person of the sovereign, and are for the most part filled by 'the prime nobility of England.' In 1839 the queen's refusal to part with the ladies of her bedchamber, on the occasion of a change in government, led to Sir Robert Peel's declining to form a ministry, and to Lord Melbourne's return to office. The incident was playfully called 'The Bedchamber Plot.' See HOUSEHOLD (THE KING'S OR QUEEN'S), and Mrs Armytage, *Old Court Customs* (1883).

Beddard, Dr FRANK EYERS (1858-1925), zoologist, was born at Dudley, educated at Harrow and Oxford, and was Professor to the Zoological Society from 1884-1915.

Beddgelert ('grave of Gelert'), a Carnarvonshire village, a great tourist centre, near Aberglaslyn Pass, 12 miles SE. of Carnarvon. The grave of the legendary hound of Llewellyn (see GELLERT) is marked by a few stones. The ascent of Snowdon is often made from this 'gem of Welsh villages,' which is the principal scene of Southey's *Madoc*.

Beddoe, JOHN (1826-1911), anthropologist, born at Bewdley, Worcestershire, was educated at Bidgorth, University College, London, and Edinburgh University, graduating M.D. in 1853. He served as a civil surgeon in the Crimean war, and afterwards established himself in practice at Clifton. He was the author of *Stature and Bulk of Man in the*

British Isles (1870), *The Races of Britain* (1886), and other anthropological and ethnological works.

Beddoes, THOMAS, physician, born at Shifnal, Shropshire, in 1760, passed from Bridgnorth grammar-school to Pembroke College, Oxford, and afterwards studied medicine at Edinburgh and London. In 1788, after taking his M.D. at Oxford, he was appointed reader in chemistry there, but his sympathies with the French Revolution rendered his post so uncomfortable that he resigned it in 1792, and retiring into the country, wrote his work *On the Nature of Demonstrative Evidence*. Several patriotic pamphlets followed, and the *History of Isaac Jenkins*, in which he laid down, in a popular style, rules of sobriety, health, &c. for the working-classes. Of this work 40,000 copies were sold in a short time. He married Anna, sister of Maria Edgeworth. In 1798, after careful study of the use of artificial or medicated gases in the cure of diseases, especially consumption, aided by his father-in-law, Mr Edgeworth, and peculiarly assisted by his friend, Thomas Wedgwood, he opened a 'pneumatic' hospital at Clifton. It did not succeed in its main object, which was to show that all diseases being referable to an undue proportion or deficiency of some elementary principle in the human organism, could be cured by breathing a medicated atmosphere; and Beddoes, whose zeal had abated, retired from it in 1801. He died 24th December 1803. The chief result of Beddoes' enterprise was the introduction to the world of Sir Humphry Davy, who was the superintendent of the institution, and who says of Beddoes: 'He had talents which would have exalted him to the pinnacle of philosophical eminence, if they had been applied with discretion;' and Southey wrote on hearing of his death: 'From Beddoes I hoped for more good to the human race than any other individual.' See the Life of Beddoes by Dr Stock (1811).

Beddoes, THOMAS LOVELL, eldest son of the above, and nephew of Maria Edgeworth, was born at Clifton, 20th July 1803. From Bath grammar-school he passed in 1817 to the Charterhouse, and thence in 1820 to Pembroke College, Oxford. In 1822 he published *The Bride's Tragedy*, which achieved a brilliant success. In 1825 he went to Göttingen to study medicine, and thenceforth led a strange wandering life as doctor and democrat, in Germany and Switzerland, with occasional visits to England. From 1825 he was engaged in the composition of a drama, *Death's Jest-book*, which, with his poems and a memoir by Kelsall, appeared in 1850-51. The story of his death by suicide at Basel (26th January 1849) was told for the first time in Mr Gosse's memoir prefixed to his edition of the *Poetical Works* (2 vols. 1890). The poems of Beddoes, almost all nominally dramatic, exhibit no power of characterisation, no ability in the conduct of a story; but the fullness of thought and image, the tone of music, and the depth of colour are marvellous.

Bede, or BĒDA, the VENERABLE, the greatest name in the ancient literature of England, was born in the neighbourhood of Monkwearmouth, in the county of Durham, about the year 673 A.D. He was educated under the care of the learned and liberal abbot, Benedict Biscop, and his successor, Ceolfrid, in the Benedictine abbey at Monkwearmouth, to which the young scholar came an orphan child in his seventh year. Ultimately he entered the monastery at Jarrow, an offshoot of the same foundation, and here he remained until his death. Here he took deacon's orders in his nineteenth year, and was ordained priest in his thirtieth, by John of Beverley, then Bishop of Hexham. In the shelter of his quiet and sacred retreat he devoted

himself to study, while he was diligent in observing the discipline of his order, as well as in the daily service of the monastery church. His industry was enormous, and he was continually employed in reading, writing, and teaching. Besides Latin and Greek, classical as well as patristic literature, he studied Hebrew, medicine, astronomy, and prosody. He wrote homilies, lives of saints, hymns (his English Death-song a valuable monument of the Northumbrian dialect), epigrams, works on chronology and grammar, and biblical commentaries. His calm and gentle spirit, the humanising character of his pursuits, and the holiness of his life present a striking contrast to the turbulent temper of his time. When near his end he translated St John's Gospel into English, dictating his version to his pupils. The well-known story of how he finished the last sentence of his version on the very day of his death casts a light on the serene and simple piety of his life. His brethren had all gone to the festival, and he was left alone with the scribe. 'Dearest master,' said the latter, 'there is one chapter wanting, and it is hard for thee to question thyself.' 'No, it is easy,' said he; 'take thy pen and write quickly.' When evening came, the young scribe said, 'There is yet one more sentence, dear master, to write out.' He answered, 'Write quickly.' Shortly after the boy said, 'Now it is finished.' 'Well,' said the aged saint, 'thou hast spoken truly "it is finished."' Then he bade them place him where he could look on the spot on which he was wont to kneel in prayer. Then he chanted the *Gloria Patri*, and as he uttered the words 'the Holy Ghost,' he breathed his last, and 'so passed to the kingdom in heaven,' on the day of the Feast of the Ascension, 26th May 735. He was buried in the monastery of Jarrow: long afterwards (in the middle of the 11th century) his bones were removed to Durham. His most valuable work is the *Historia Ecclesiastica Gentis Anglorum*, an ecclesiastical history of England, in five books, to which we are indebted for almost all our information on the ancient history of England down to 731 A.D. Bede gained the materials for this work partly from Roman writers, but chiefly from native chronicles and biographies, records and public documents, and oral and written communications from his contemporaries. It was translated into English not by King Alfred, but under his authority. At the end Bede gives a list of his thirty-seven works. His *De Sex Aetibus Mundi* was an important book in chronology. 'First,' says Green, 'among English scholars, first among English theologians, first among English historians, it is in the monk of Jarrow that English literature strikes its roots. In the six hundred scholars who gathered round him for instruction, he is the father of our national education.' He is, moreover, the first English churchman whose books were accepted as standard works by the whole Catholic Church, and carried the fame of English learning throughout Western Christendom.

Among the editions of Bede's History may be noticed those printed at Strasburg in 1473-1500; those by Smith (1722), Stevenson (1838), Hussey (1846), Moberley (1869), and Holder (Freiburg, 1882); and the standard edition of the *Opera Historica* by C. Plummer (2 vols. 1896). The complete works were published in Paris (6 vols. folio, 1544-45), Basel (8 vols. folio, 1563), Cologne (1612 and 1688), London (12 vols. 1843-44) by Giles, and at Paris in Migne's *Patrologia* (xc.-xov., 1844). The History was Englished by Stapleton (1655), Stevens (1723), Hurst (1814), Giles (1840), Stevenson (1852), Gidley (1870), and Sellar (1907). See Hodgkin in the *Polit. Hist. of Eng.* (vol. i. 1906), Stopford Brooke's *English Literature to the Norman Conquest* (1898), the short Life by G. F. Browne (1880; new ed. 1918), and Roger, *L'Enseignement Classique d'Ausone à Alcuin* (1905).

Bedeau, MARIE ALPHONSE, a French general, born near Nantes in 1804, entered the army in 1825. Sent in 1836 to Algeria, as commandant of a battalion he took part in most of the military operations, and in 1847 was for three months governor of Algeria. In 1848 he was commissioned by Marshal Bugeaud to suppress the February revolution in Paris, but failed. He took office under the Provisional Government, and was named vice-president of the Constituent Assembly, always voting with the Republican party. Along with Cavaignac and Lamoricière he was arrested in December 1851, and went into exile; he died at Nantes, 30th October 1863.

Bedeguar (Persian and Arabic *bādāwar*, literally 'wind-brought'; sometimes explained as made up of Persian *bād*, 'wind,' and Arabic *ward*, 'rose'), a remarkable gall of roundish shape, but covered with shaggy branched processes, like those familiar in the moss-rose, often found on the branches of various species of rose, particularly of the sweet-brier, upon which account it is sometimes called sweet-brier sponge. Although of course sharing the astringent properties of Galls (q.v.) in general, it has long ceased to be of any medicinal repute. See GALL-FLY.

Bedell, WILLIAM, Bishop, born at Black Notley, Essex, in 1571, was educated at Emmanuel College, Cambridge. From 1602 to 1613 he was incumbent of St Mary's at Bury St Edmunds, save that during 1607-11 he was chaplain to Sir Henry Wotton, the British ambassador to Venice, where he made the friendship of Father Paul Sarpi. In 1616 he retired to the neighbouring parish of Horningsheath, whence in 1627 he was called to become provost of Trinity College, Dublin. Two years afterwards he was promoted to the united bishoprics of Kilmore and Ardagh, the latter of which he resigned in 1633. He immediately set himself to reform the crying abuses that prevailed in his diocese, and with so happy a combination of wisdom, firmness, and charity, that even his enemies were constrained to do homage to his virtues. The translation of the Old Testament into Irish was accomplished under Bedell's direction (the New had been already translated). On the breaking out of the rebellion in 1641, his popularity for some time saved his family from violence, his being the only English house in County Cavan that was spared. At length he was seized and imprisoned in Loughoughter Castle. He was soon allowed to remove to the house of a Protestant clergyman at Drumlor, but there catching a fever, he died 7th February 1642. See the Lives by his son and by A. Clogie, edited by Shuckburgh and Mayor (1902).

Bedford, the county town of Bedfordshire, is situated on the navigable Ouse, 49 miles NNW. of London by rail, and in the midst of a broad expanse of rich pasture and corn lands. The Ouse is spanned here by two bridges—a stone one of five arches, 306 feet long, built in 1811 at a cost of £15,000, and an iron one, built in 1888 at a cost of £6000. Bedford itself is clean and well paved, and the drainage and water-supply have been greatly improved. The charitable and educational institutions are mostly due to Sir W. Harpur, Lord Mayor of London (d. 1573). He in 1566 founded a free school, and endowed it with 13 acres of land in Helborn. The enormously increased value of the property (from £150 to £15,000 a year) enables the trustees to maintain grammar, modern, and preparatory schools for boys, the same class of schools for girls, and almshouses. Under the scheme (1874) of the Endowed School Commissioners, the funds are divided thus: One-eleventh to the almshouses; two-elevenths to elementary education;

four-elevenths to the grammar-school and high-school for girls; and four-elevenths to the modern schools. The county school was opened in 1869. The chief manufacture is that of agricultural implements. Lace-making is also carried on; straw-plaiting has declined. An embankment beside the Ouse forms a pretty promenade; and a people's park was opened in 1888. Till 1885 Bedford returned two members to parliament, till 1918 one. Pop. (1851) 12,693; (1921) 40,247. Bedford is of great antiquity, and is mentioned in the *Anglo-Saxon Chronicle* under the name of Bedican-fortlia, as the scene of a battle between the Britons and Saxons in 571. The Danes burnt it in 1010. Afterwards its old castle, said to have been built by Edward the Elder, is frequently mentioned in history. Bunyan (q.v.), who was born at Elstow, near Bedford, was for twelve years a prisoner in Bedford gaol, and ministered to the Nonconformist congregation in Mill Lane from 1672 to his death in 1688. His chapel has been twice rebuilt, in 1707 and 1849; but his chair and other relics of him are preserved; whilst a colossal bronze statue of him by Boehm was erected at the cost of the Duke of Bedford in 1874. New buildings for the grammar-school were opened in 1891, and the recreation-ground of 22 acres gifted by the Duke of Bedford in 1894. In 1894 a bronze statue of John Howard (q.v.) was erected.

Bedford College. See WOMEN'S RIGHTS.

Bedford, JOHN, DUKE OF, third son of Henry IV., was born about 1389. During his father's lifetime he was governor of Berwick-upon-Tweed, and warden of the Scottish marches. In 1415 his brother, Henry V., created him Duke of Bedford; and during the war with France he was left in command of the forces in England. After Henry's death (1422), Bedford went to France to look after the interests of the infant prince, his nephew. The regency of France he offered to the Duke of Burgundy, who refused it; he then assumed it himself. On the death of Charles, a few months after Henry V., Bedford had his nephew proclaimed king of France and England, as Henry VI. In the wars with the dauphin which followed, Bedford displayed great generalship, and defeated the French in several battles—most disastrously at Verneuil in 1424. But, in consequence of the rather parsimonious way in which men and money were doled out to him from England, and the withdrawal of the forces of the Duke of Burgundy, he was unable to take full advantage of his victories. The appearance of Joan of Arc, notwithstanding his utmost energy, was followed by disaster to the English arms; and in 1435 a treaty of peace was negotiated at Rouen between Charles VII. and the Duke of Burgundy, which effectually ruined English interests in France. The death of Bedford, which took place September 19, 1435, fourteen days before the ratification of that treaty, was mainly, if not altogether, occasioned by his anxiety and vexation on account of the union thus formed. Bedford, who was a patron of letters, purchased and removed to London the Royal Library of Paris, consisting of 900 volumes. For the present dukedom of Bedford, see RUSSELL.

Bedford Level, an extensive tract of flat land in the east of England, embracing nearly all the marshy district called the Fens. It extends inland around the Wash into the six counties of Northampton, Huntingdon, Cambridge, Lincoln, Norfolk, and Suffolk, and has an area of about 750,000 acres. Its inland boundary forms a horseshoe of high lands, and reaches the towns or villages of Brandon, Milton (near Cambridge), Earith, Peterborough, and Bolingbroke. It is divided into three parts—the north level, between

the rivers Welland and Nene; the middle, between the Nene and the Old Bedford River; and the south, extending to Stoke, Feltwell, and Mildenhall. It is intersected by many artificial channels, as well as by the lower parts of the rivers Nene, Cam, Ouse (Great and Little), Welland, Glen, Lark, and Stoke. It receives the waters of the whole or parts of nine counties. This district seems to have been a great forest at the time of the Romans, who cut the forest down, formed great embankments to exclude the tide, and rendered the tract for a time a fertile inhabited region. In the 13th and other centuries violent incursions of the sea stopped the outflow of the rivers, and it became a morass. The practicability of draining this extensive region seems to have been thought of in 1436, and many partial attempts were made after this. The first effectual effort was in 1634, when Francis, Earl of Bedford, after whom the district was thenceforth called, obtained, along with thirteen others, a grant of 95,000 acres of the reclaimed land on condition of draining the level. The work was partially accomplished in three years, at a cost of £100,000; but was pronounced inadequate by government. Charles I. tried to get the work, with a greatly increased premium, into his own hands; but the civil war stopped further progress. In 1649 parliament confirmed William, Earl of Bedford, in the rights granted to his father; and after a fresh outlay of £300,000, the contract was fulfilled. In 1688 a corporation was formed for the management of the level. The middle level has always been the most difficult to manage; and the work on it, with one drain 11 miles long, was only completed in 1852 at a cost of £400,000. The St Germain's sluice, at the confluence of that drain with the Ouse, was considered perfectly secure. But in May 1862 it gave way under the pressure of a strong tide, and the western bank of the middle-level drain burst, speedily flooding about 6000 acres of fertile land. This led to the construction of a permanent cofferdam of pile-work to shut off the tidal waters; and for the drainage of the middle level, Slater's Lode sluice was taken advantage of; siphon pipes being laid over the cofferdam, the flood-waters let off by them and by drains, the siphons acting as permanent sluice.

See books by Heathcote (1876), Miller and Skertholp (1879), Miller (1890), the Duke of Bedford (1897), and *Fenland Notes and Queries* (1891-1899).

Bedfordshire, a midland county of England, surrounded by Hunts, Cambridgeshire, Herts, Bucks, and Northants. It is one of the smallest of English counties. Extreme length, 31 miles; breadth, 25; area, 461 sq. m. The general surface is level, with gentle undulations. In the south, a range of chalk hills, branching from the Chilterns, crosses Bedfordshire in a north-east direction from Dunstable, and another parallel range runs from Ampthill to near the junction of the Ivel with the Ouse. Between the latter ridge and the north-west part of the county, where the land is also somewhat hilly, lies the corn vale of Bedford. No hill in Bedfordshire much exceeds 500 feet in height. The chief rivers are the Ouse (running through the centre of the county, 17 miles in a direct line, but 45 by its windings), navigable to Bedford; and its tributary, the Ivel, navigable to Shefford. By these rivers Bedfordshire communicates with the counties of Cambridge, Huntingdon, and Norfolk. The south and south-east parts of the county consist of chalk, and the north and north-west of oolitic strata. Freestone is quarried, as well as chalk or clunch, to be burnt for lime. The soil varies greatly. In the south of the county it is chalk thinly covered with earth, and fit only for sheep-walks; but three-fourths of the county is

clay, which is very stiff between the Ivel and Ouse. A rich gravelly loam exists along the rivers. In the vale of Bedford the soil is chiefly rich clay and deep loam; and to the north the clay is stiff, poor, and wet. There are extensive market-gardens, especially on the rich deep loams. Bedfordshire is the most exclusively agricultural county in England, its cultivated area being 88.1 per cent., against 79.3 for the whole kingdom. Pop. (1891) 63,393; (1881) 149,473; (1921) 206,478. The principal proprietor is the Duke of Bedford; and his seat, Woburn Abbey, is the chief mansion. Lace-making and straw-plaiting—for which Dunstable is celebrated—are leading industries, and they are carried on almost entirely by women. Three members of parliament are returned for the county of Bedfordshire, one each for the Bedford, Luton, and Mid divisions. Many British and Roman antiquities exist in the county, as well as the ruins of several monasteries, and some fine relics of Romanesque and Gothic architecture among the parish churches. Three Roman roads crossed the county. See the 'Victoria History' (1904 *et seq.*); C. Gore Chambers, *Bedfordshire* (1917); and a book on place-names by Mawer and Stenton (1926).

Bedlam (now officially written *Bethlem*), the London lunatic asylum, originally founded in 1247 as a priory at Dishopsgate, its mother church being St Mary's of Bethlehem (or Bedleem in Wycliff's spelling). It is spoken of as a hospital for lunatics in 1472, and as such it was granted at the dissolution to the mayor and citizens of London, being incorporated as a royal foundation in 1547. In 1676 it was transferred to Moorfields, and in 1815 to St George's Fields, Lambeth, and a further change of site is projected. The present hospital was extended in 1838; but when Broadmoor was built in 1863, the criminal wings were pulled down. In the old Moorfield days the management of Bedlam was deplorable. The patients were exhibited to the public, like wild beasts, as we see in Hogarth's picture, and read in Pepps and Boswell; *Northward Ho* bears witness to the same custom in the 18th-century period. Before 1675 convalescents, wearing badges, were turned out to beg in the streets; Edgar, in *King Lear*, personates one of these 'Tom-o'-Bedlams.' Even in 1815 there was no glazing, warming, or lighting of the cells, and some inmates were kept in chains.

Bedlington Terrier, a breed originated about the beginning of the 19th century by Mr Aynsley of Bedlington, near Morpeth, in Northumberland, to which county it was almost entirely confined for many years. Its chief points are the following: Muzzle, long and fine, but very powerful; head, high in the skull and rather narrow, the hair on the top being softer and of a lighter colour than on the rest of the body; eyes, small, dark, and slightly sunk; ears, rather large and filbert-shaped, hanging close to the cheeks, and slightly feathered; neck, long, slender, but muscular; body, well proportioned, and deep chested, though rather lightly ribbed; legs, straight and somewhat long; tail, of moderate length, tapering to a point, with no feather; coat, fine but not soft, short and rather thin; colour, liver or sandy, with flesh-coloured nose, or blue-black, with black nose, the latter being the commoner colour; weight, from 16 to 20 lb.; height, 13 inches. The Bedlington terrier is remarkably high couraged, and makes a splendid vermin dog, on account of its activity and pluck, and will face even an otter or badger without flinching. It also makes a capital water-dog, and may be broken to the gun, its speed and cleverness being highly useful.

Bedmar, ALFONSO DE CUEVA, MARQUIS DE, born in 1572, won an enduring notoriety on account

of his daring and unscrupulous plot for the destruction of Venice, to which city he had been appointed ambassador from the court of Spain in 1607. He first leagued himself secretly with the Duke of Ossuna, viceroy of Naples, and Don Pedro of Toledo, governor of Milan, then purchased the services of a large number of foreign mercenaries, while Ossuna furnished him with a band of privateers, or rather pirates. The day chosen for carrying out his purpose was that on which the doge wedded the Adriatic, when all Venice was intent on beholding the august ceremony. Fortunately, the night before, one of the conspirators betrayed the plot. Several persons were executed; but curiously enough, Bedmar, the arch-delinquent, was only dismissed. The event forms the subject of Otway's *Venice Preserved*. Bedmar now went to Flanders, where he became president of the council, and in 1622 was made a cardinal by the pope. He then went to Rome, and finally returned to Spain as Bishop of Oviedo, where he died in 1655.

Bednor', BEDNUR, or NAGAR, a decayed city, now a village, of Mysore, India, situated in the midst of a basin in a rugged tableland of the Western Ghats, at an elevation of more than 4000 feet above the sea, 150 miles NW. of Seringapatam. It was once capital of a rajah, with a population of 100,000, and in 1763 it was taken by Hyder Ali, who pillaged it of property worth £12,000,000.

Bed of Justice (Fr. *lit de justice*; Lat. *lectus justitie*, *lectus* being a couch as much as a bed), literally, the seat or throne occupied by the French monarch when he was present at the deliberations of parliament. Historically, a bed of justice signified a solemn session, in which the king was present to overrule the decisions of parliament, and to enforce the acceptance of edicts or ordinances which it had previously rejected. The theory of the old French constitution was that the authority of parliament was derived solely from the crown; consequently, when the king, the source of authority, was present, that which was delegated ceased. Acknowledging such a principle, the parliament was logically incapable of resisting any demand that the king in a bed of justice might make, and decrees promulgated during a sitting of this kind were held to be of more authority than ordinary decisions of parliament. Monarchs were not slow to take advantage of this power to overawe any parliament that exhibited signs of independence. The last bed of justice was held by Louis XVI. at Versailles in September 1787, when the whole parliament were arrested and confined in prisons in different parts of France.

Bedos de Celles, DOM FRANÇOIS, a Benedictine monk of the congregation of St Maur, and the most learned and practical master of the art of organ-building in the 18th century. He was born at Caux in 1706, and entered his order in 1726 at Toulouse. He was elected a member of the Academy of Sciences in 1758; in 1766-78 was published for the academy his great work, *L'Art du Facteur d'Orgues*, in 4 vols. large folio, with 137 copperplates, beautifully executed. He died in 1779.

Bed'ouins (Arab. *Beduân*, 'dwellers in the desert') are Arabs who lead a nomadic life. The most ancient notices found in Scripture agree, in their descriptions of the manners and customs of the Bedouins, with the facts of the present time. As nomads, the Bedouin Arabs have no united history, but only a collection of genealogies. They have but seldom appeared as a united people taking a prominent part in the world's politics, and have never been entirely held in subjection by any

foreign power. The desert of Arabia is their central place of abode; but even in ancient times they had spread themselves over the deserts of Egypt and Syria; and in later times they entered Mesopotamia and Chaldea. The conquest of Northern Africa in the 7th century opened up to them still vaster tracts. At present they are to be found from the western boundary of Persia to the Atlantic, and from the mountains of Kurdistan to the negro countries of Sudan. In the cultivated lands of Mesopotamia, Chaldea, the Syrian confines, Barbary, Nubia, and the north of Sudan the Arabs are found intermingled with other nations; but in the deserts they have maintained their distinct character and independence. They form a seventh part of the population of Arabia. The characteristics of the Bedouins, as herdsmen and robbers in the desert, are intimately connected with the nature of their habitation. Their abstinent, precarious, and often solitary mode of life makes them disposed to exercise mutual hospitality; but their independence, love of liberty, and other good qualities, are associated with violent passions and an infamous love of plunder, reckless of the rights of property. They are lean, sinewy, and active, but commonly below middle stature. Their senses, especially sight, are keen; the nose is commonly aquiline; in complexion they are of various shades of brown. With the exception of certain tribes in Syria, all the Bedouins are professedly Mohammedans, but are as much Sabæans, and have, beyond a belief in one God, extremely little religion. Clergy are unknown, except where dread of the Wahabis extends. Though the Bedouins' intellectual powers are naturally good, they are miserably destitute of solid knowledge. Their endless tales and poetical effusions show a wonderful activity of imagination and an oriental love of hyperbole. The relation of the sexes to each other is less constrained than among the settled peoples of the East. Bigamy is rare, polygamy scarcely known; divorce of the wife is extremely common and easy. Their diet is principally derived from their herds, but includes rice, a few vegetables, honey, locusts, and even lizards. They manufacture their own woollen clothing. Many tribes shave the head; but among all the beard is a favourite object of cultivation. The political condition of the Bedouin is patriarchal. One or more families form the core of a tribe, and constitute a kind of aristocracy. Out of their number the superior *sheikh* is elected, who leads those of the tribe that choose to follow, and the *kadi*, who judges between such litigants as accept his award. But custom is law, and each tribesman is his own executive. This sketch of the Bedouin applies chiefly to the true nomads, or 'dwellers in the desert,' and is subject to modifications with regard to tribes in Barbary, Syria, and Mesopotamia, who practise agriculture, and dwell in houses.

Bed-sores are often a very troublesome complication of illness, to which a patient is liable when, confined for a long time to bed, he is either unable or not allowed to change his position. Their occurrence often prevents successful results in the most careful medical treatment, or the most brilliant surgical operations which would otherwise be quite successful, as their presence depletes vitality, offers an opening for the entrance of disease germs, and prevents cure, more than any other adverse circumstances can do in cases of prolonged treatment in bed. They attack the skin over bony prominences, especially the lower parts of the spine, the haunch-bones, the heel, and the elbow. The skin becomes red at first, and its surface is gradually abraded; this may end in the death of a portion of the skin, which separates

as a *slough*, and a deep ulcer appears beneath it. General debility, the continued fevers (especially typhoid), paralysis, and old age are strong predisposing causes. The immediate causes are continuous pressure on the affected parts and a lack of care in nursing, as, for instance, incomplete cleanliness, where the evacuations escape involuntarily, and where the undersheet is not kept smooth and free from irritating particles. Hence in all cases of prolonged confinement to bed the parts naturally pressed upon by the weight of the body should be carefully examined every day. When a long confinement to bed is expected, attempts should be made to thicken the cuticle, and enable it to bear pressure better, by rubbing the skin with a stimulant such as spirits or eau-de-Cologne. If the part, when first seen, looks red and rough, further damage is often prevented by covering it with a piece of lint on which vaseline has been spread; the local pressure may be removed by air-cushions specially constructed for cases of this kind, and in many instances a water-bed affords great comfort. If the case is one in which it is admissible, the patient should be made to alter his position frequently. Should an abrasion form, it must be treated by the application of dressings of damp boric lint. At this stage, also, all pressure must be removed from the part if possible. When the dusky colour of an insulated piece of skin shows that a *slough* is forming, a water-dressing must be applied, and renewed every eight hours. It consists of four layers of boric lint cut a little larger than the size of the livid portion of skin. The lint, wrung out of hot water, is covered by a piece of oiled silk that overlaps it for half an inch in every direction. When the slough separates, a similar dressing should be continued for the ulcer, on the surface of which a little iodoform is sprinkled before the water-dressing is applied. In severe cases a 'prone couch' should be used, on which the patient lies on his face. This gives great relief, and allows healing to take place.

Bedstraw (*Galium*), a genus of Rubiaceæ (q.v.). The species are very numerous, natives chiefly of the colder parts of the northern hemisphere, or of mountainous regions within or near

A, Common Great Bedstraw (*Galium elatum*);
B, Yellow Bedstraw (*Galium verum*).
a, flower; b, fruit.

the tropics. About eleven species are found in Britain, some of them very common weeds. Amongst these is Our Lady's Bedstraw, or Yellow Bedstraw (*G. verum*)—sometimes called Cheese

Rennet, because of some obscure use in cheese-making in the past (the generic name, Gr. *gálon* from *gála* 'milk,' belonged to some unidentified plant)—a small plant with linear deflexed leaves and dense panicles of bright yellow flowers, very abundant on dry banks. The flowering tops, boiled in alum, furnish the Icelanders with a bright yellow dye; while the Highlanders used to employ the root-stock for dyeing yarn red. Their colour being essentially that of the allied madder, the cultivation of the plant was attempted many years ago. Certain North American species, especially *G. tinctorum* and *G. septentrionale*, have been used in the same way. Like madder, they possess the property of imparting a red colour to the bones and milk of animals which feed upon them. Medicinal virtues were ascribed to some of the species, as *G. rigidum* and *G. mollugo*. The roasted seeds of some, as *G. aparine*, the troublesome Goosegrass, or Cleavers (q.v.), have been recommended as a substitute for coffee. Its expressed juice is in some countries a popular remedy for cutaneous disorders, and is used as a diuretic. The roots of *G. tuberosum* are farinaceous, and it is cultivated in China for food. The name *bedstraw* is due to the old legendary name of one of the species, 'Our Lady's Bedstraw,' analogous to 'Our Lady's Garters, Mantle, Slippers,' &c.

Bedworth, a market-town of Warwickshire, 3 miles S. of Nuneaton.

Bee. Bees form a group of insects in the order Hymenoptera, in the same sub-order (Aculeata) as the wasps and ants. Like other Hymenoptera, they have four membranous wings, with few nervures, and the hind-wing has a row of hooks which fix on to the fore-wing, so that the two move as one in flight; the mouth parts are suited for biting and for sucking or licking; the first ring of the thorax (the prothorax) is fused with the next segment, the mesothorax; the metamorphosis is complete. As in most other Aculeata, the females, including the workers, have a protrusible sting (a modified ovipositor) at the end of the abdomen; a narrow waist or stalk is formed between the first and second segments of the abdomen; the male has thirteen joints in its antennæ, and the female twelve; the larvæ are footless grubs which are reared in special 'cells.' In bees in particular (Apiariæ) the body is thick and short, and usually hairy; the hind-legs, especially the posterior pair, are usually broadened, and have a brush of hairs suited for the collection of pollen; and the first and second maxillæ are elongated so that they more readily reach the nectar in the deep cups of many flowers.

History.—Bees must have been among the first insects to engage human attention. Their comparatively large size, abundant occurrence, social life, and honey-storing habits appear to have been from very early times facts of common observation. Aristotle has gathered up some of the opinions of his contemporaries in regard to bees—opinions, however, in which much fancy is mingled with some acute observations. Virgil has described the habits of bees in his fourth Georgic with all the license of a poet and the enthusiasm of a lover of nature. Pliny repeats, as he was wont, all the floating bee-gossip of his time, but without criticism or analysis. For about fourteen centuries after Pliny, bees were unmolested by the naturalist, and were, as far as we know, only thought of as the sources of occasional luxury. With the Renaissance, however, the natural history of bees became again the subject of study. Works by Edward Wotton and Conrad Gesner contain numerous trustworthy observations, and were the preface to a series of careful studies by

various naturalists in the latter half of the 17th century. Conspicuous among these are the works of Swammerdam (*General History of Insects*, 1669); the memoirs of Maraldi (1712), who is said to have been the first to use glass-hives; and the clear observations of John Ray and his friend Willughby. On a higher plane of detailed anatomical research stands the immortal work of Réaumur (*Mémoires pour servir à l'Histoire des Insectes*, 1732-44), from which the systematic and thoroughly scientific study of bees may be said to date. His contemporary Bonnet also was the author of numerous important observations; while among the crowd of naturalists who have worthily continued the researches of Réaumur, the patient and ingenious Huber is undoubtedly pre-eminent (*Nouvelles Observations sur les Abeilles*, 1814). The more modern experimental method of investigation is well represented by Sir J. Lubbock's (Lord Avebury's) researches (see *Ants, Bees, and Wasps*).

Form and Structure.—Before noting the more important features in the anatomy of the bee, it is necessary to recall the familiar fact that many kinds of bees are social, that is to say that they live in communities. The following observations apply to the hive-bee. As in the case of ants, various sets of members have come to discharge special functions, and the result of this division of labour has been difference of form, or polymorphism. In fact, the result of restricted function has been the establishment of castes. Thus the ordinary hive contains (1) a single queen-bee—the fertile female and mother of the next brood, (2) the males or drones, and (3) the vast majority of workers or imperfectly developed females, which only exceptionally become fertile. In describing the anatomy, the ordinary hive-bee (*Apis mellifica*, L.) will be principally referred to. Like that of other insects, the body of the bee is readily divisible into three portions—head, thorax, and abdomen. The head is well defined from the body, and bears the organs of sight, touch, mastication, and honey-collecting. There are two compound eyes, borne on the sides of the head. They are largest in the males, and meet on the crown. Besides these there are, on the top of the head, three eye-spots or ocelli, concerning the exact function of which there is some difference of opinion. Below the eyes are (1) two jointed feelers or antennæ, most essential organs of sensation. The basal joint is much the largest, and the stalk formed from the eleven or twelve smaller ones extends outwards at a sort of knee-like angle (geniculate). In the antennæ of the males there are thirteen joints; in those of the females, twelve. (2) Next come the horny, toothed mandibles, freely articulated to the head, and well adapted for cutting the resinous cement or propolis into shapes, for the finer work of handling the pollen, for biting through the corollas and other obstructions of flowers, and the like. The other two pairs of head appendages are greatly modified for collecting the nectar from the flowers. (3) The first pair of maxillæ are much elongated flattened blades, embracing the second pair, and forming the outer sheath of the proboscis, as the entire collecting organ is called. They form the outer wall of a sort of suction-tube. The tips of these blades, however, remain sharp, and act as efficient piercing organs. The external portions of this first pair of maxillæ, the so-called maxillary palps, degenerate, and only remain as much-reduced structures with a few joints. (4) The fused basal portion of the second pair of maxillæ, the mentum, as it is called, is in movable membranous and elastic connection with the cardines or bases of the first pair.

This mentum bears internally the long structure known as the *ligula* or *tongue*. This is a much

elongated slender hairy organ of varying firmness throughout its course. It occupies a number of very different positions according to the business of the bee at the moment, but a description of these would involve inconvenient detail. The four main positions are very lucidly depicted in Hermann Muller's *Fertilisation of Flowers*. When at rest, the internal portion of the tongue is somewhat

Fig. 1.—Mouth Organs of Honey-bee (*Apis mellifica*):
a, tongue; b, b, labial palps; c, c, first maxillæ.

curled up and retracted into the lower end of the mentum. It is capable of very rapid protrusion and of free motion in almost every direction. The external lateral portions or labial palps are comparatively small, and consist of two long and two short joints. Their tips remain as tactile organs, while their internal joints are elongated to form a sheath for the base of the tongue. Between the palps and the tongue there are also two very small structures known as *paraglossæ*. The whole proboscis thus consists of hairy tongue, of minute paraglossæ, of insheathing labial palps (all belonging to the second pair of maxillæ), and further, of external maxillary blades and reduced palps belonging to the first pair. The hairs which cover the tongue appear to serve for the upward passage of honey. The successive whorls have been seen to be erected from before backwards so as gradually, but rapidly, to sweep the nectar to the mouth. The expanded lobe at the tip of the tongue is thrust into the nectar, and a little appears to pass up a central capillary tube to the taste organs, by which the bee determines whether the food does or does not suit its taste. The tip may also be used to lick flat surfaces. The upward passage of the nectar among the hairs on the outside of the tongue and within the outer sheath is doubtless helped by the sucking action of the sides of the body, and of the first part of the food-canal. According to a recent investigator (Breithaupt), the honey may pass up either by the great suctorial tube of the proboscis, or when that ceases to be efficient, by the capillary tube of the tongue, but the exact action of this complex and beautiful organ is not yet thoroughly understood. The tongue of the workers is twice as long as that of the queens or the drones, who do not collect honey.

The somewhat oval thorax bears the two pairs of wings and three pairs of legs, and consists of the usual three segments, of which the most anterior (the prothorax) is greatly reduced. The wings,

which are borne on the last two segments, are membranous and transparent. When at rest, they are folded together over the back; when in action, the two pairs are clasped together by means of small hooks on the fore margin of the hind pair. Perhaps it was this close union of the wings which suggested to Linnaeus the name Hymenoptera or 'wedded-wings,' though the term may simply refer to the fact that the wings are membranous. The arrangement secures a very steady and rapid flight. The many-jointed mobile legs do not differ from those of other insects, except in the high development of pollen-collecting hairs. In the workers the hind pair of legs exhibit on their central joint a spoon-shaped cavity fringed with bristles, so as to form an efficient pollen-basket. The pollen is kneaded by mouth and fore-feet, and shifted by the middle pair of legs to the safe hollow behind. The two terminal claws of the feet are used when the bees climb and hang, while the membranous lobe between the hooks probably aids in handling minute bodies and in clambering on smooth slippery surfaces.

The *abdomen*, or posterior portion of the body, is joined to the thorax by a comparatively narrow bridge. The margins of successive segments overlap, and the whole region is capable of free respiratory movements. Like other parts of the body, the abdomen has a dark-brown colour, with somewhat lighter cross bands. The females bear at the end of the body an ovipositor or sting, which consists of a median piece deeply grooved on its lower surface and of two adjacent sharply pointed structures, which being apposed to the median piece, make the groove into a canal. The internal end of the canal thus formed is in connection with the female generative aperture, so that the eggs can pass neatly down from the body of the bee into the cell prepared as a cradle.

Fig. 2.—Sting of Worker-bee (*Apis mellifica*).
(After Kraepelin);

a, poison gland; b, poison bag; c, accessory gland; d, d', outer supporting pieces; e, inner sheath inclosing sting proper. A, sting proper; B, sheath in which sting works, seen from below.

But the base is also connected with a poison-bag containing formic acid and other irritants, which are squeezed into the wound made by the sharp sting, and are the obvious causes of the familiar inflammation. In the queen-bees this specialisation of abdominal appendages forms a long, stout,

curved organ, which is occasionally used as a weapon in duels with rivals, but much more frequently for its main business as an egg-laying organ; in the workers it is rarely used except as a sting; in the drones it is represented by the external male genital organs.

The Internal Organs.—The Food-canal.—The nectar drawn up by the proboscis passes through a short pharynx into a narrow gullet. In the abdominal region this expands into a crop or honey-sac, a transparent bag, filled with honey in the bees returning heavy laden to the hive. This crop opens by a complicated funnel and stopper into the digestive stomach, which is followed by the coiled intestine. Opening into the anterior region of the food-canal there are three or four pairs of salivary and other glands. In the worker the nectar may reach the stomach and be digested, or it may be delayed in the crop and regurgitated into the cells of the comb.

The Nervous System.—As in other insects, the nervous system consists of a ganglionic mass above the gullet (the brain) and of a ventral chain of ganglia, of which the anterior are connected with the dorsal mass by means of a nerve-ring round the gullet. The two posterior ganglia in the thorax are fused into one, and beyond this are five or six abdominal ganglia. The presence of these separate nerve-centres or ganglia in the body explains the apparent vitality of bees and other insects for some little while after the removal of the head.

The circulatory, respiratory, excretory, and reproductive systems do not differ markedly from those of other insects. The usual dorsal chambered heart is present. The main stems of the tracheæ or air-tubes, by means of which the air passes throughout the whole body, are very large and dilatable, especially in the abdominal region. The buzzing of bees is partly due to the rapid movement of the wings, and partly to the vibration of the stigmatic membranes which guard the entrance to the air-tubes. The excretory system is represented by long thread-like 'Malpighian tubes' which open into the intestine. The queen is the only fertile female with fully developed reproductive organs, but the workers have vestigial ovaries and may occasionally lay eggs. It may be by accidental or by deliberate change in the nutrition that a worker becomes occasionally reproductive. The female reproductive organs of a queen-bee consist principally of ovaries, oviducts, ovipositor, and a storing-chamber for the male elements, known as the sperm-reservoir or spermatheca. The eggs are fertilised just before they are laid by spermatozoa from the spermatheca. But some are not fertilised, and these develop into drones. Thus drones have a mother, but no father. It has been reported that spermatozoa may remain alive for two or even three years in the spermatheca of the queen-bee. All the ova of the bee seem to be of the same kind, and all undergo what is called reducing division or meiotic division (see CELL) in the process of maturation or polar-body-forming. The number of nuclear bodies or chromosomes is reduced to one-half the normal number, say from

n to $\frac{n}{2}$ All the spermatozoa are said to have $\frac{n}{2}$

chromosomes. The fertilised ova have $\frac{n}{2} + \frac{n}{2} = n$ chromosomes, and develop into queens and workers—functional and arrested females. The unfertilised ova have $\frac{n}{2}$ chromosomes, and develop into males.

Functions and Habits.—It has been already noted that the social life of bees has resulted in some division of labour. At the beginning of spring the hive contains a single queen and

a much-reduced contingent of workers. Their first care is to restore the normal population. Towards this end the queen lays numerous eggs which develop into *workers*. After the stock has been thus replenished, eggs are laid which turn out males or *drones*. After they begin to appear, eggs are laid which develop into more *workers*, and also into a few *queens*. The rapid increase of population culminates in the emigration known as *swarming*, when the old queen leads off a large contingent of subjects. The date of swarming is markedly affected by the temperature and the food-supply. The symptoms of emigration are such as these—a clustering of bees in small dense crowds outside the hive, a commotion among the drones, a suspension of the labours of the workers, the excitement of the queen-mother, and, in the case of second or third swarms, the piping of the still imprisoned young queens. She is exasperated by the presence of possible rivals in her own household, and would ruthlessly kill her royal children, were they not guarded by the workers. In the case of swarms centred around an old queen, it seems customary to send out scouts to explore the land before the bees take any decisive steps towards emigration. When at length the pressure and excitement has reached a climax, the emigrants rush out with great rapidity. They form a spreading crowd, concentrating, however, round the egg-laden queen, who is rarely able to fly far. During swarming, the bees are singularly quiet, and may be safely handled. Should the queen be lost or removed, the bees soon return much depressed to their old home. The workers seem to take with them a heavy load of honey, and they at once set about building a comb, in the first cells of which the queen, losing no time, lays some eggs. The disruption of swarming obviously robs the old hive of its queen, but there are princesses ready to be liberated, and these may soon lead off fresh swarms.

A populous stock will often send off three in rapid succession. When the season and necessity for swarming is past, the young queens that remain imprisoned in the royal cells are liberated at once and allowed to fight for the sovereignty. The survivor takes her nuptial flight. By one, or perhaps several, of the males she is impregnated, though some authorities believe that the fertilisation is effected by

drones from another hive. After impregnation has been accomplished, the young queen settles down to begin her egg-laying; she continues this throughout the rest of the summer. When swarming time is over, and the supply of honey decreases, the bees commence to rid the hives of the drones, henceforth mere useless consumers. They appear to drive them into a corner, and keep them without food until their

powers of resistance are much weakened. They are then turned out of doors to perish, for the workers seem rarely to use their stings. Even the infant pupæ and the eggs are destroyed. The fact of this massacre

suggests the difficult problem of the meaning of so many males. Their number, of course, insures the fertilisation of the queen. Romanes suggests that the numerous drones represent a survival of past times when the society was less complex, and when the females were probably more numerous, and the males less idle. If there is any chance of drones being needed, when for instance the queen is barren, and fresh ones have to be reared and fertilised, they are allowed to live beyond their usual term. On the other hand, when unfavourable weather prevents swarming, the workers in their despair sometimes massacre the drones.

The queen-bees are reared from special eggs, which begin to be laid after the drones appear on the scene. According to some, the queen herself deposits in the special royal cells the eggs which develop into future queens; according to others, the workers shift the eggs into these specially large cradles. They develop very rapidly in consequence of rich nutrition, attaining their maturity in about sixteen days. The queen is always treated with much respect and care, unless she turn old or become barren. An intruding stranger-queen is not always treated with respect, but may be pulled about by the workers for hours until she dies, and is thrown out of the hive. A queenless hive, without any prospect of a new sovereign, becomes completely demoralised and restless, but in this case a stranger is gladly adopted.

Just as the drones and queens maintain the numbers of the hive so far as reproduction is concerned, so the supplies of food are collected by the myriads of workers. Among these there is some slight division of labour. Members of the community varying in age and constitution, are told off to special tasks. Thus we can distinguish the external workers who collect nectar and pollen from those who attend to more internal domestic duties. Some of the internal workers, usually the young bees, act as nurses, effecting the mastication and semi-digestion of the food for the young larvæ, and caring for all the needs of the brood; while some wait upon the queen. Others again devote their energies, for a time at least, to the architecture of the cells, for which some of the heavy eaters secrete the wax. Others attend to the ventilation of the hive, which is apt to become hot enough not only to be disagreeable, but to soften the wax. These ventilators fan industriously with their wings, and produce air-currents through the hive strong enough to blow out a lighted match. 'When they are tired they are relieved by others.'

Feeding.—Bees feed principally on the nectar and pollen of flowers. In spring they frequent the early-flowering willow, hazel, plane, apple, pear, alder, gooseberry, currant, &c. Later on they turn to the crowfoot, clover, vetch, turnip, cabbage, dandelion, buckwheat, balsam, privet, elder, bramble, and other flowers, which yield abundant nectar and are accessible to their probosces. The borage, the mignonette, the thyme, the heathers, the teasel, are also valuable sources of food. Plants like the furze, which keep flowering for a long time, are obviously of great value to bees and bee-keepers. Some flowers abounding in nectar are avoided because of their strong smell, others like the red clover and the honeysuckle are inaccessible to bees with a proboscis not larger than that of the common hive-bee. Attempts have been made in Britain to rear varieties which would be able to utilise the abundant red clover, inaccessible to the common bee.

When the bee proceeds to rob a flower of its

Fig. 3.—Honey-bee (*Apis mellifica*): keep them without food until their

powers of resistance are much weakened. They are then turned out of doors to perish, for the workers seem rarely to use their stings. Even the infant pupæ and the eggs are destroyed. The fact of this massacre

general action of the suctorial proboscis, helped by muscular contractions of the body, or by an ascent up the fine capillary tube of the tongue, the nectar is conveyed to the mouth. Thence it passes down the gullet into the honey-bag, and is partly used for the sustenance of the worker itself, being digested in the stomach, and passing thence to the body generally. A large surplus, however, remains as a contribution to the honey-store of the hive, which is stored up for consumption during the flowerless season. Where there is no real winter, as in warmer countries (Australia and California), imported European bees tend to lose their storing instinct, and to become idle.

Besides the nectar, the *pollen* of flowers is essential to the normal life of bees; it is the ambrosia of the hive, and is largely used as food for the young. As the nectar is non-nitrogenous, the necessity for some other kind of food is obvious. Drones and queens, however, never eat raw pollen, and must therefore get their nitrogen indirectly. The special food supplied to the young is formed from pollen partly digested along with honey. The pollen is collected by the hairs of the body, from which it is cleaned off by the feet and jaws, damped with dew or other moisture, mixed with a little honey ejected from the mouth, kneaded into pellets, taken up by the brushes on

the hind-legs, and deposited in the baskets in which it is carried home. The cargo thus brought to the hive may be immediately seized by the nursing bees, or may be stored up for future use. In the first case it is worked up by the nurses into a suitable state and given to the larvæ. In the other case the worker frees itself from its burden, pulling it off with its fore-

Fig. 4.

Hind-leg of Honey-bee, A; Humble-bee (*Bombus lapidarius*), B.

legs over a cell in the comb, and starts off again for more, while another bee packs the pollen into the cell, with the addition of a little honey, and covers it over with a varnish. The industrious collectors restrict themselves on each journey to a particular kind of pollen. Bees may also consume the juices of plants, and do not hesitate to suck the bodies of the deceased or murdered grubs. In periods of scarcity, large quantities of the juices ('honey-dew') of aphides, and other small insects, may be stored.

It is difficult to understand on the principles of a selfish philosophy the extraordinary industry of the workers in their food-collecting. It cannot be called greed, since it is more for the good of the society than for their own. It is also well known that the rage for plunder often prompts bees to engage in warfare. Many individual bees try robbery on their own account, attempting to sneak into neighbour hives. In other cases four or five act in concert as highway robbers, waylaying some honey-laden victim, and outrageously despoiling it. It is even said that simple intimidation sometimes results in a submissive handing over of spoil. But in other cases a whole army of bees attacks a hive probably supposed to be at once rich and weak.

Their first care is to demoralise their enemies by killing the queen. This done, the rest is generally easy, and the panic-struck owners may even help the invaders to carry home their own honey.

Bees also collect a resinous, strongly adhesive, reddish-brown substance, known as *propolis*. This is obtained chiefly from the resinous exudations of such trees as fir, poplar, alder, birch, willow, horse-chestnut, &c., and is much used by the bees as a cement. With it they varnish the combs, stop up holes, and 'strengthen the outworks of their city.' It may also be used for stranger and more occasional purposes, such as sealing up an intruding snail. The bees carry it home on their legs; other workers clean it off, and utilise it while still ductile, mixing it with various proportions of wax according to the use to which it is put. Bees also appreciate the honey-dew which appears on the leaves of many trees and herbs, usually in association with aphides.

Secretion.—The wax used in the construction of the comb is manufactured by the bees themselves. It has been shown that they are able to form it even when fed exclusively on honey. After a heavy meal, they often hang together in a small festoon, and secrete large quantities in this state of repose. The secretion is exuded from eight wax-pockets situated on the ventral surface of the abdomen. The wax projects in small flakes between the rings, is removed by the legs, shifted forward to the mouth, masticated by the jaws, and laid in heaps for the use of the comb-builders. In a young hive these wax scales may be found in thousands upon the floor.

Another secretion of a very different nature is the poison. This consists of a transparent fluid with much formic acid and other irritant components, and is secreted by workers and queens in a venom-bag situated near the end of the alimentary canal. There the waste products of honey literally form poison, which flows down between the two barbed piercing organs forming the main part of the sting. The scabbard or sheath of the sting has been already referred to as the ovipositor. The barbed form of the sting makes it very difficult for the bee to withdraw it after striking its foe, and thus death is generally the nemesis of passion, though, as we have seen, this is avoided in the massacre of the drones. The queens have longer and stouter stings than the workers, but are very slow to use them. They rarely have occasion to do so in fact, except in their duels with other rival queens. The best precaution against being stung is quietness. Of the numerous curative applications, ammonia solution (hartshorn) is one of the most serviceable. See POISONS.

In regard to secretion, it is only necessary to notice further that the bee-larvæ, like so many other young insects, secrete a certain amount of silk to form chrysalis-robes.

Hive-life.—During winter and early spring the bees remain at home, but the temperature of the hive (usually 45° F. at least) shows that they are not asleep. In March or April the work of the year begins—the hive is cleaned, the dead bodies are removed, and the queen begins to lay. We have noticed how the first eggs produce workers developing in twenty-two days; how a second set become drones developing in twenty-five days; and how in midsummer some eggs develop (in sixteen days) into young queens; how the birth of workers increases the population, much reduced during the winter; and how in a short time a swarming occurs.

Cell-building.—The bee 'combs' consist of a series of waxen cells constructed by the workers for storing honey and as cradles for the young. They hang perpendicularly within the hive, firmly fixed to the walls. Each consists of a double

row of cells disposed at right angles to the comb. Each cell of this two-sided comb is a hexagonal prism, with its internal apex lying in the depression between three adjacent cells on the opposite side. Of the three figures—the equal-sided triangle, the square, and the hexagon—which can be packed together without interstices, the hexagon is strongest and most convenient. To have the bottoms of the cells formed from three planes of adjacent cells on the opposite side economises labour and material. The amount of possible saving varies with the angle at which the three planes meet. Maclaurin showed by calculation that the angle of the bee-cell was mathematically the best. Though perfect regularity is disputable, there still remains a marvellous accuracy to be explained. On the one hand, some supposed, and one may almost say suppose, that the bees really know what they are about, and that they have by experiment solved the problem. On the other hand, others have tried to give either a mechanical or an historical explanation of the beautiful result. Thus Buffon sought to explain the hexagonal form as the result of the mutual pressure of crowded cylinders. He called attention to analogous results when soap-bubbles are crowded together, or when peas crammed into a bottle expand with boiling. While some, like Brougham, who have repeated this last experiment, denied that regular hexagons resulted, others have corroborated Buffon, and asserted that some of the figures formed are those of the bee-cells. Buffon's mechanical theory was, however, discredited, and indeed laughed at, by most authorities on bees, and the assumption which flattered the intelligence of these insects held ground till Darwin attacked the problem.

Darwin discussed the facts in the main from an historical point of view. He pointed out that at one end of a series the humble-bees either use their old cocoons for honey storehouses, or improve them slightly by the addition of short tubes, or build separate irregular rounded cells. At the other end of the series the hive-bees build their beautiful framework. But between these there are gradations, especially that exhibited by the Mexican *Melipona domestica*. This bee makes a comb of cylindrical cells for its young, and larger spherical cells for honey. These are placed so close that if the spheres were completed they would intersect. This is not, however, permitted, for the bees build flat plates between the cells which tend to intersect. Thus each cell presents an outer spherical portion and two or three or more flat surfaces. As one cell often rests against three others, a pyramid is formed by the union of three flat surfaces. Now if the *Melipona* made its spheres at a given distance from one another and of equal size, the result would be the hive-comb type. Darwin then resorted to experiment. He placed plates of wax in the hive, and on these the bees proceeded to excavate circular pits at equal distances, so that as they were completed the surfaces intersected. When this occurred, the bees built up flat walls along the lines of intersection. 'The work of construction,' he says, 'seems to be a sort of balance struck between many bees, all instinctively standing at the same relative distance from each other, all trying to sweep equal spheres, and then building up, or leaving ungnawed, the planes of intersection between these spheres.' Darwin thus called attention to the gradual evolution of the habit from less perfect expressions, and appealed, of course, to natural selection as tending to develop an instinct which was obviously economical of space, material, and labour. This account of the historical evolution of the habit does not, however, exclude the possibility of purely physical

factors having much more to do with the actual solution of the problem than Darwin supposed. A recent investigator of this much-debated point, Dr Mullenhof, reverts very much to Buffon's position. After emphasising the perfect plasticity of the wax at the temperature of comb-building (27°-37° C.), he maintains that the beautiful result is not due to any artistic dexterity on the part of the bees, nor to any direct effect of their body-form, but 'to statical pressure according to the laws of equilibrium.' The cells are such as would naturally result from pressing the maximum number of cylindrical cells into the minimum of space. They really behave, he maintains, as softish cylinders would do in conditions of mutual pressure and continued plasticity. They form equilibrium figures with the smallest surface for given contact. But at anyrate it is, on the one hand, certainly gratuitous to credit the bees with the mathematical insight of senior wranglers, and equally unnecessary, on the other, to ignore the neatness and precision of their manipulation.

Into some of the cells honey is placed for winter use. In going up and down over the full cells, bees have been seen to protrude their stings, and to deposit drops of poison on the honey. This has an antiseptic influence, due to the presence of formic acid, without which the honey would ferment. In other cells pollen is stored after being salivated and compressed by indoor workers. A pollen-cell is (frequently at least) sealed with honey, and over this a thin cream-like pellicle is formed, which can be pushed aside for the deposition of more honey, or walked over without causing overflow. But of equal importance are the brood-cells, the cradles of the future young bees. These vary slightly in size. Those for future workers are smaller and lower; those for the drones are broader and longer. In spring-time, after the drones have begun to appear, the royal cradles are formed for the young queens. These cells are usually made at the edges of the combs, have their mouths turned downwards, and are of a large size and more irregular form. In other cases they are merely modified worker-grub cells.

Life-history.—As in the majority of insects, the life-history is divisible into four chapters—the developing egg, the larva or grub, the pupa, and the perfect insect. (1) The eggs have a long oval shape, and a whitish colour. They are, barring an exception already noticed, all laid by the so-called queen. After normal fertilisation she becomes, in fact, little more than an egg-producing machine, turning them out sometimes at the rate of 100 per hour or 3000 per diem, and is often fed while at her work, so that the expenditure of living matter is to a certain extent recouped. If a young queen be not impregnated in the first three weeks of her life, she continues laying drone-eggs only, as above described. The discriminative process of fertilisation of the ova is highly noteworthy: in laying an egg in a worker-cell the queen's abdomen has to be contracted, and a drop of seminal fluid is thus brought into contact with the egg: in the case of the larger drone-cell there is no such abdominal contraction, and consequently no fertilisation of the ovum. The egg is fixed by its end to the base of the cell, and thus it remains for between three and four days, when the worm-like grub appears. (2) The grub grows like any other insect larva, and as it touches the sides of its cell, coils up in a crescent, and floats in the food which has been left in the cell. As it gains strength, however, it rears up to the mouth of the cell and eagerly devours the food supplied by the nursing workers. After the sixth day the worker-grubs only receive unmanicured food. The result is the stunting or atrophy of their reproductive

system. With the queen-grubs it is very different. The grub is seen literally wallowing in the rich and carefully elaborated royal jelly; and this abundant and stimulating nutrition is naturally believed to be the condition of the perfect development of the reproductive system exhibited by the queen-bees. (3) In several days, varying slightly with the season, the grub passes into another stage of its life-history. It has grown greatly and accumulated some reserve material to serve it throughout a period of fasting. The cell is sealed up by the nurses, and the grub becomes a *pupa*. The queen is 5½ days a larva and 8½ days a pupa, the worker 6 and 11, the drone 6 and 15 days respectively. The nursing workers seal up the cell with a cap of wax, which is more convex in the drone-cells, and in all cases different from the paler, somewhat concave, cover of the honey-cells. The imprisoned grub does not at once fall into inactivity, but proceeds first to spin its chrysalis-robes. Alternately contracting and elongating its body, it at the same time allows filmy threads to exude from the orifices of spinning-glands situated on its lower lip. There are two such organs, and the resulting thread which the grub weaves round itself is therefore double. In a day and a half the worker-grub has spun a complete cocoon, and becomes a true resting pupa or bee-nymph. The male-grubs also spin complete cocoons, but those of the queen-grubs only inclose head, thorax, and the first ring of the abdomen. In this connection it is worth noticing, as an illustration of depraved teleology, that, according to Hübner, the final cause of these incomplete cocoons is that the pupæ may be more readily exposed to the sting of the jealous first-born queen, whose instinct prompts her to kill off all possible rivals.

Within the curtain of the cocoon important changes occur. The mummy-like pupa is gradually modified into the young bee. The skin, the segments, the appendages, and the internal organs undergo most marked changes, and on the twentieth or twenty-first day after egg-laying the young insect finally bursts its swaddling-clothes, and emerges as a winged perfect insect or *imago*. They break open their cocoons with their jaws, and are assisted by the kindly workers; they clean themselves of moisture and shreds, and proceed to eat after their long fast. In some cases, after a preliminary meal, they proceed at once to gather honey, but the first flight is usually postponed for about a week, the intervening time being spent in indoor employment. The empty cells may be repeatedly used over again as cradles, or may be filled with honey. The young queens are not allowed to escape when their metamorphoses are over. In the door of their cell a small hole is made, through which the royal prisoners are fed till the tone of their piping probably intimates their complete sexual maturity. If the queen should be lost, and there be no royal grubs, a new queen may be literally manufactured. A young worker-grub is simply fed up to the required pitch in an enlarged cell of the proper spaciousness.

The different members of a bee-community enjoy lives of very varied duration. The drones live from May till August, but were it not for the massacre, would doubtless live much longer. Contrary to the opinions of the ancients, who credited bees with an existence of as much as six or even ten years, the workers seem to have in summer an extremely short but hard-working life, which probably averages about six weeks. Those born in autumn live on till the next spring, though many perish in the hard times of winter. A queen, on the other hand, will live from three to five years.

Diseases and Parasites.—There are several very

serious diseases of hive-bees, some due to bacteria, and another due to a protozoon in the same genus, *Nosema*, as the parasite which causes the silkworm disease (pebrine). 'Isle of Wight disease' has been traced to a mite (*Tarsonemus woodi*) inhabiting the first pair of spiracles. Bees are, like many other insects, subject to the attacks of parasites both on their bodies and within their nests. On the adult bee lice are common pests, while the larvæ of the ichneumon do great damage to the grubs; but the honey-bees are apparently exempted from the attacks of the latter. The adult honey-bee is greatly troubled by the Bee-louse (*Brachia caeca*) and by the Bee-fly (*Phora incrassata*). The larvæ are often devoured by a species of beetle (*Trichodes*). A hairworm of white appearance occurs abundantly inside the diones only. The wild bees are similarly infested by numerous parasites, such as the larvæ of ichneumons, the minute *Anthophorobia*, which may be obtained in hundreds on breaking open a few cells of the leaf-cutter and other species. From larval intruders found in the nest of the wall-bee Lampert reared no fewer than nine different parasites belonging to the Hymenoptera, Coleoptera, and Diptera. Parasitism also occurs between bee and bee. Thus, the 'cuckoo-bees,' *Apathus* and *Nomada*, live at the expense of hosts no larger than themselves, with which, however, they seem to preserve a curious sort of harmony. On the other hand, the larvæ of *Stelis nasuta*, found in the nest of the Wall-bee (*Chalcidodoma muraria*), seems to devour not only the food, but the lawful tenants.

Senses.—The sight of bees is well developed; they are able to distinguish objects at some distance, and show a marked preference for certain colours, as might be almost inferred from the history of bee-fertilised flowers. Lord Avebury showed by experiments with baits of honey on strips of paper of different colours that they can distinguish green, yellow, red, and blue, and prefer blue to all. Pink also appears to be a favourite colour. Like other insects, they are attracted to light. Much has been observed in regard to the power bees have of finding their way straight home. Avebury's careful experiments have shown that the so-called 'sense of direction' is not in all cases a sufficient guide, but must be aided by definite registering of landmarks over the space traversed. This they are certainly able to do, and they can also remember their visual impressions for a considerable time. The sounds made by bees at their respiratory openings or stigmata are not restricted to a monotone, but vary considerably, as in the familiar case of the responses of the queen-bee to the piping of the princess pupæ. From the variable sounds, apparently expressive of emotion, it has been inferred that bees are also able to hear. Lord Avebury was, however, unable to get them to take any notice of any sound which he could devise, though he was disposed to believe that they can hear higher notes.

Some of the mouth parts, such as the inside of the tongue, evidently act as organs of taste, and are able to discriminate between different kinds of nectar. Bees have also an acute sense of smell, but how far this is physiologically separated from taste is uncertain. It is probably by a fine sense of smell that bees are able to recognise the members of their own hive, and to detect an unwary wanderer or thievish intruder of another house. Sprinkling them with some strong scent appears naturally to obliterate this power. In connection with the recognition of strange bees, it is worth while quoting Mr Langstroth's observation that a stranger laden with honey is received with open arms, while a hungry marauder is very summarily dealt with. 'There is,' he says, 'an air of roguery

about a thieving bee which, to the expert, is as characteristic as are the motions of a pickpocket to a skilful policeman. Its sneaking look, and nervous, guilty agitation, once seen, can never be mistaken.

Lord Avebury's experiments have shown that bees possess a certain power of communication, and other observers also, such as Fritz Muller, have recorded cases where the workers were able in particular ways to bring their friends to some treasure-trove, or in some way told one another the sad news of the loss of their queen, and the like. How they can communicate any definite impression to their fellows is a mystery, but observers have noted that they tap one another with their feelers, and that the notes emitted from their respiratory apertures differ somewhat in character. The antennæ are most essential organs of sensation; and an animal deprived of them exhibits a high degree of bewilderment and incapacity virtually amounting to insanity.

Intelligence.—Bees have thus keen sight, enabling them to distinguish objects and colours; acute smell, quick to detect, for instance, stranger bees or attractive food; and presumably a fine sense of hearing, fit to discriminate between the import of slightly varying tones in one another's voices. But they have more, inasmuch as they exhibit in their actions what can only be fairly described as intelligence. Without entering into any discussion, it may be useful here to recall the rough distinction between those instinctive reasonable actions which have become habitual, and those which exhibit a power of accommodation to new conditions or change of habit in the face of new problems. This whole subject, so far as at present understood, is well discussed in Romanes's *Animal Intelligence and Mental Evolution*, on the first of which the following summary is based. To begin at a comparatively low level, bees exhibit indubitable instances of *memory*. They are not only able accurately to register visual impressions of a locality so as to be able to find their way thither, even after considerable intervals, but they can associate their impressions so as to be able, for instance, to recognise a human friend, and have in some cases been tamed and tained. Lord Avebury also tells how a bee remembered what it had been shown—that the way out of a bell-jar held with its closed end against a window was not to endeavour to get through the pane, but out at the open end.

It is obvious further, from what has been already said of the habits of bees, that many features in their domestic and social economy suggest foresight and purposeful determination. Such a conclusion must, however, be made with great caution in regard to all actions or sets of actions which are distinctly habitual and shared by the whole race. That several surplus queens are reared to make up for losses; that worker-grubs can, if occasion demand it, be promoted by feeding into queens; that the young queens are not liberated till the old one leads off her colony, and then generally in gradual succession; that the workers allow the rival queens to settle their own affair by duel in which the fitter probably survives; that they massacre their drones when these are no longer of use; and that they do a dozen similar things, is doubtless marvellous, but the marvel must not at least be exaggerated by forgetting that they have been forced and drilled into these reasonable habits throughout the very long history of their social organisation. On the other hand, when an unusual juncture in the social relations occurs, and the bees act sagaciously in extraordinary conditions, then there is purposeful intelligence to admire. Thus Romanes quotes two observations of F. Hübner to the following effect:

Two sole surviving queens, prompted by their instinctive jealousy, were engaged in mortal combat, and were so situated that a simultaneous double sting would end the life of both—an obvious disaster to the hive. They released one another, and intelligence triumphed over instinct. And again, a hive was left queenless, with the not uncommon result that the remaining bees set about manufacturing some new queens from worker-grubs. Hübner restored the old sovereign, and the bees at once proceeded to remove the royal food from the worker-grubs, so as to counteract their previous, but no longer useful intention of rearing new queens. The submission of the bees of an invaded hive when they find that their queen has been killed, is also a curious instance of discretion, and the variations occasionally exhibited in connection with drone-killing, are no less suggestive of intelligence. Again, it is a fact, which any one can verify, that bees bite through the corollas of many tubular flowers near the nectaries, in some cases as a lazy trick to save time, in other cases as an ingenious device to reach nectar inaccessible by the normal process of stretching the proboscis down the corolla tube.

The careful *ventilation* of an over-heated hive is evidently an adaptation to an abnormal state of affairs which would not occur in the roomy natural hives, and ought not to occur in the artificial. 'It follows,' Buchner writes, 'that the fanning and ventilating can have absolutely nothing to do with an inborn tendency or instinct, but have been gradually evoked by necessity, thought, and experience.' In regard to *cleanliness* also, intelligent adaptations of much interest are exhibited. When possible, the excrement is voided outside; in winter the faeces may be retained till the first fine day; bees have even been known to make a kind of drain for the removal of the waste matter, which, when voided in the hive, often causes dysenteric and other fatal diseases. Small intruding animals, such as slugs, are known to be sealed up with propolis, while an intruding mouse, for instance, too large to be safely left in this way, was killed, and gnawed into bits, which were carried piecemeal outside. The bodies of deceased bees are also removed outside the hive. In regard to their *treatment of intruders*, besides the welcome of those bearing gifts, and the rough detection of those with evil intent, their clever device by which they fortify the hive against their formidable enemy the death's-head moth is extremely suggestive. Hübner was the first to notice that, as the result of repeated attacks, the bees were taught by sad experience to build at the entrance a barrier of wax and propolis, with a hole large enough to admit them and small enough effectually to exclude the invader. Whatever opinion may be held in regard to the intelligence displayed in the habitual *architecture*, there can be little doubt as to the inference to be drawn from cases in which the building habits are modified to suit peculiar conditions. Bees have been seen to make repeated trials of different plans in special cases, as when two combs meet at an angle, to pull down bad workmanship and rebuild it, to adopt ingenious devices when the sides of the hive were made of smooth glass, and so on. To Hübner 'the purest reason seemed to shine out' from the action of the bees in a hive where a piece of comb fell from its proper position. Wiser than many builders, they strengthened the attachments of all the other combs, 'clearly because,' as Romanes notes, 'they inferred that they too might be in danger of falling.' Many similar instances have been recorded.

Emotions.—The intellectual development associated with the complex social relations of bees seems much greater than the culture of their emotions.

Sir John Lubbock describes them as 'thoroughly callous and utterly indifferent to one another,' except, indeed, when attention to their comrades was for their own advantage, or part of the ordinary business of their life. He notes how they pay no regard whatever to the sudden death of a comrade beside them, nor even to the struggles of one in trouble. Other observers, both ancient and modern, give them credit for a little more sympathy, and have noticed cases, perhaps exceptional, where they did seem to exhibit active compassion for an unfortunate fellow-worker.

Relation to Flowers.—It is now well known that in the majority of flowering plants the female cell is fertilised by male elements or pollen grains carried by insects from another flower of the same species. Insects, more especially bees, and flowers have, in fact, grown up together in mutual dependence and with mutual influence. They have perfected one another. Bees are attracted to suitable flowers partly, no doubt, as the result of experience, but also by odours, and especially by colours.

Fig. 5.

A, Honey-bee on broom-flower; B, Wild-bee on white dead-nettle.

These colours exhibit a gradual evolution from yellow to blue. They 'follow a regular law of progressive modification, but have been fixed and stereotyped in each species by the selective action of the proper beetles, bees, moths, or butterflies.' Blue colour is characteristic of many highly-developed flowers, and bees are especially fond of this blue colour, probably because they have learned to associate it with flowers peculiarly suited to their access and taste, and the result of this preference is to insure the fertilisation and survival of the higher flowers. And again, numerous flowers, especially those visited by the higher bees, exhibit mechanical adaptations which insure that the bee in diving down for the nectar becomes thoroughly dusted with pollen. The wild sage (*Salvia*) and the orchis are two good examples of very different modifications securing fertilisation. There can be little doubt that at least the more mechanical of these pollen-dusting contrivances have resulted as direct adaptations in association with the continual visits of bees. See FLOWER (*Fertilisation*).

Pedigree of Bees.—These adaptations are, however, mutual ones: just as flowers have been modified in relation to bees, so have bees in relation to flowers. Bees thus appear to be the last result of a long series of progressive changes, the steps of which are still to some extent discoverable. According to Hermann Muller, the primitive ancestor was a form like the common sand-wasp, carnivorous in its diet, and bringing its insect or spider prey to its larvæ. From these arose forms which adopted a floral diet, and thus filling up a more or less unoccupied corner in nature's household, got on amazingly well. They thrive, were

fruitful and multiplied, and were, in the course of time, likewise modified into the numerous types of modern bees. The chief modifications, as above noticed, are associated with the development of social life, the elaboration of honey-sucking mouth structures, and the equipment with pollen-collecting appliances. Muller's main stages are as follows:

(1) Starting from the sand-wasp, we find in *Prosopis* a bee but slightly advanced above the ancestral type. It is almost hairless, with mouth parts but slightly elongated, and feeds its young on honey and pollen, which are simply crammed into the brood-chamber. (2) *Sphecodes*, *Halictus*, and *Andrena* occupy a somewhat higher level. They are more efficient pollen-collectors, inasmuch as they have become hairy. In the first there appears the first trace of feathery-collecting hairs, and the primitive fashion in which they feed the young with the disgorged surplus of food is also interesting. *Halictus* has more hairy hind-legs, and special brushes on some of the terminal joints. The young are fed with pollen. In *Andrena* the whole hind-leg is hairy. (3) *Dasyptoda* and *Panurgus* exhibit yet another step in the direction of more efficient pollen-collecting. The hairs occur on the long tibia (second-last portion) and on the terminal part or tarsus. (4) The last step in this direction is exhibited by those forms in which the pollen is moistened with honey before it is stowed away. In *Mâcropis*, heaps of consolidated pollen are fixed without special contrivance to the hind-legs; in *Bombus* (humble-bee) the outer side of the hind-legs exhibits the familiar pollen-basket fenced in with long hairs—an obvious economy of both hairs and time; while *Apis* (honey-bee) shows a yet more evolved arrangement of collecting-brushes and receiving-basket. Besides those forms with collecting-hairs on the hind-legs, culminating in *Apis*, there is a separate division, in which the pollen is collected on the lower surface of the abdomen upon brushes or backward-directed bristles. The mason-bee (*Osmia*) and the leaf-cutter (*Megachile*) are good examples. In the same way, Muller traces throughout a series of gradations the evolution of the honey-collecting organs. This progress is chiefly concerned with the lengthening of the tongue and the extension of the membranous and elastic parts between the bases of the two pairs of maxillæ (between mentum and cardines). The tongue is in the lower bees decidedly shorter than the basal joint or mentum, but ends with becoming very much longer. The first pair of maxillæ also elongate into insheathing laminae for the tongue, and the same is true of the proximal joints of the labial palps (i.e. of the external lateral portions of the second pair of maxillæ). In power of extension and retraction, in equipment with honey-catching hairs, in the differentiation of a terminal lobe, &c., the tongue exhibits a progressive evolution.

Evolution of Social Life.—Just as among ants, so with bees we have to distinguish solitary and social genera, of which the former are greatly in the majority, and, in origin at anyrate, the more primitive. Starting from completely solitary forms, we next find bees whose nests are individually separate, but at the same time closely adjoin those of their neighbours. From such a beginning the various grades of development up to the complex social life exhibited in the communities of humble and honey bees are still distinctly traceable.

(a) **Solitary Bees.**—Colletes is a common and widely-distributed genus, the females of which closely resemble the common honey-bee. The males differ in several features, and are decidedly

smaller. They form colonies of considerable size in loose soil or in the soft mortar of walls. Each cell is lined with a fine coating resembling gold-beater's skin. *Prosopis* is also a common bee of wide distribution. It closely resembles a sand-wasp, and is destitute of the usual means of carrying pollen, being on that account long regarded as a parasite. They make their cells in the pith of bramble-sticks, and line them, like *Colletes*, with a delicate membrane. The British species appear in June, and continue during the two succeeding months. When handled they give off a pleasant odour. The genus *Sphecodes* includes four British species, of world-wide distribution, but of infrequent occurrence. They also are often regarded as parasites on other bees (*Halictus*), but Mr F. Smith's observations go to show that both in burrowing and pollen-gathering they are entirely independent. The nests occur, indeed, side by side with those of *Halictus*, but each bee seems to keep to its own home. In spring females alone are met with, while in autumn both sexes occur together. The genus *Andrena* is the most numerous of all the Apidæ, the British species alone numbering sixty-three. They have been fitly called the harbingers of spring, as they appear even in the cold of March. They are all burrowers, making holes which measure from 6 to 12 inches in depth, and give off lateral passages, each terminating in a cell. In this the female deposits its egg on the top of a mass of pollen about the size of a pea. After devouring this, the larva falls into a lethargy, which lasts till the following spring, when the rest of the metamorphosis is rapidly completed.

Halictus is a large genus, the members of which resemble *Sphecodes* in many characteristics, and in this among others, that they alone among solitary bees are impregnated in the autumn, and remain dormant during winter. The most beautiful bees found in Britain are the wasp-bees or *Nomada*. In their gay colours they resemble wasps. They are widely distributed in the northern hemisphere. Their life-history is still veiled in obscurity, little being known beyond the fact that they enter the hives of other bees (*Andrenidæ* and *Apidæ*). All the British species emit when captured very agreeable balmy odours. The mason-bee, or *Osmia*, includes a large number of species with most interesting diversity of instincts. They occur abundantly in temperate climates, and their nests are found in the most diverse localities, from the shells of snails to the branches of brambles. In regard to these wood-boring bees (such as *Xylocopa*), it has been a commonly received opinion, originating with Réaumur, that the young forms at the lowest portion of the excavated tunnel escaped first, and that the others followed suit in regular order from below upwards. Each young bee had thus simply to cut its way through the bottom partition of its cell, towards which its head was said to be pointed, and was thus not only saved trouble, but kept from disturbing the less mature inmates of the upper stories. This pretty observation is, however, denied by Mr Smith, with respect to the numerous British wood-boring bees. *Megachile*, the genus of leaf-cutters, is the most cosmopolitan of all genera of bees, and three hundred species are known to exist. They all excavate burrows in the ground or in wood, which they line with cuttings from the leaves or petals of flowers. *Anthophora* is a very numerous genus, of world-wide distribution, and includes one hundred and thirty species, of which four occur in Britain. Some of them are true carpenters, and others are burrowers.

(b) *Social Bees*.—The genus *Bombus* includes one hundred species, of which twenty are British. Of all the wild bees, the species of *Bombus* (humble-bee) are the most familiar, being extremely conspicuous on account of their large size

and noisy hum. In different parts of the country they receive different names, such as bumble-bees, hummel-bees, dumble-dores, foggie-bees, &c. Some species build their nests on the surface of the ground amongst moss and grass (e.g. *B. muscorum*, *B. pratorum*, and *B. elegans*), while others form subterranean homes (e.g. *B. lapidarius*, *B. subterraneus*, *B. virginialis*). At the first approach of spring, the females, which have been hibernating, come forth from their retreats, and at once set about establishing a homestead, choosing for instance the deserted abode of a shrew, or simply looking for a cosy nook on the surface. Having found a convenient site, the bee builds a nest of withered grass, moss, &c., in the centre of which a mass of pollen mixed with honey is then deposited. On this she lays several eggs, side by side, and covers them over with pollen. When the eggs hatch, the larvæ eat their way in different directions into the surrounding store until they reach their full growth, when they spin for themselves a strong oval cocoon. At the side of the mass are a set of shallow receptacles containing coarse liquid honey. These are probably designed either for the moistening of the pollen, or as a store for a rainy day. Within the cocoon the larvæ soon become perfect insects, but are not on emerging ready for active work, nor equipped with their full-coloured dress. The empty cocoons afterwards serve as store-chambers. The workers appear to issue first, and to take upon themselves the entire maintenance of the colony, while the queen now restricts herself more or less completely to maternal duties. Along with more workers small females appear, which are not unnaturally supposed to be only capable of producing drones. Later on the drones appear, while the last brood consists solely of large females, which, on being fertilised, hibernate, and thus complete the life-history.

The industry of the humble-bees appears to surpass that of any other bees, which is saying a great deal. From the earliest morning till the last streak of evening light, they seem to continue most indefatigably at work. The temper and courage of the different species varies very considerably; the nests of the surface-bees are readily taken, while the underground homes can hardly be outraged with impunity. No species is more courageous than the red-backed *B. lapidarius*. In autumn, however, the courage seems to wane, and a general listlessness prevails; the males especially being often found on the heads of thistles and other composites in a dazed and helpless state, capable only of twisting their legs over their head and back in a beseeching fashion, this condition being more probably due to the stupor caused by cold, than to over-indulgence in nectar. *Bombus* has a curious semi-parasitic double-goer, called *Apathus*, which is a very shadow of its host, and is thus able to enter the nest without molestation. The parent deposits her eggs in the pollen of a humble-bee nest, the larvæ are reared with those of the latter, and the adults enter and leave the nest as if perfectly at home. The association is by no means a friendly partnership, for the aristocratic idlers gather no pollen, and prey upon the innocent *Bombi* with which they live. They consist entirely of males and females, are veritable 'cuckoos,' and do no good to the flowers which they may visit.

Different Kinds of Honey-bees.—The genus *Apis*, to which the hive-bee (*Apis mellifica*) belongs, has a cosmopolitan distribution, and numerous local varieties have arisen in response to peculiarities of habitat and nutrition. The number of true species is a point of considerable debate. The fifteen enumerated in the General Catalogue of Apidæ published by the British Museum, have

been reduced by Mr F. Smith to nine—viz. *A. dorsata* (India, Borneo, &c.), *A. zonata* (Celebes), *A. indica* (India, Java, Sumatra, &c.), *A. nigro-cincta* (Celebes, Borneo, &c.), *A. sinensis* (China), *A. florea* (India, Ceylon, Borneo, &c.), *A. adansonii* (Africa), *A. unicolor* (Madagascar, Rodriguez), *A. mellifica* (cosmopolitan). Of the last there are several varieties.

Within the limits of this article it has not been possible to do more than touch on some of the most important facts in regard to bees. Enough, however, has been said to show that the perfected complexity of their social state, the marvels and mysteries of their family relations, the exquisite adaptations of their structure, the dexterity and intelligence of their work, and the part they have played in the history of flowers, justify us surely in sharing the enthusiasm of those who, from the time of Aristotle downwards, have gained in the study of these insects some insight into the wonder and beauty of nature. See ANTS, FLOWER (*Fertilisation*), HONEY, HYMENOPTERA, INSECTS, WASPS, &c.

BEE-KEEPING as a source of profit has largely extended in recent years, owing to the improvement of modern appliances, and the more thorough knowledge of the habits of the honey-bee. The only species of bee cultivated in Europe for its honey-gathering powers is the *Apis mellifica*. Different varieties have been tried, but those now in more common use are the Italian bee, the Carniolan, the Dutch (said to be immune to Isle of Wight bee disease), and the common black bee of the country. Opinions differ as to the value of these races, but probably quite 85 per cent. of British bee-keepers consider the black bee the most profitable and suitable for this country. Some of the other races are too vicious, and others too much given to swarming. A good honey-gathering bee is produced by crossing some of the varieties, but its temper is usually uncertain.

In Italy and elsewhere queens are raised on a large scale, put into small cages along with food and a few bees, and transmitted through the mails all over the world. In consequence of this, in some parts of the country it is difficult to find absolutely pure black bees.

Hives.—It is necessary to the well-being of a colony of bees that their hives should protect them from the changeable influences of the weather. While the hive should be light, so as to be easily moved about, its walls should be thick enough to protect the bees from the extreme cold of winter and the excessive heat of summer, and should be constructed of a material that will effectually protect them from rain, cold, or damp. The hive in use in Britain for ages past has been made of straw, sewed tightly together with narrow belts of cane or bramble. The straw-skep answered the purpose of its construction very well, being light, comfortable, and durable, and formed a picturesque object. The straw-hive is unknown in America, the frame-hive, and sometimes a wood box being the only forms known. In Russia round logs of wood, hollowed out in the centre, are largely used. The introduction of the movable comb method of management has made the skep give way to what is known as the frame-hive; and now in many parts of Scotland and England the straw-skep is looked on as a relic of the past. The principle of the movable comb hive is of very ancient origin, having been employed by the Greeks; but it has been reserved to our own times to develop it. To the Rev. L. L. Langstroth, an American bee-keeper, belongs the credit of conceiving a hive in which the combs are built in frames hung side by side in a box. The Langstroth hive made its appearance in the United States in 1851, and since then profitable bee-keeping has advanced

rapidly. The great advantage gained by the movable comb system of management is that the capacity of the hive may be regulated to accommodate any number of bees, however great or small.

As winter comes on, and the bees decrease in number and cling more closely together, the hive is contracted by means of one or two division-boards, so that the internal heat is economised. As spring advances comb by comb is added until the hive is full. Other advantages of the method are that weak hives may be strengthened by combs taken from more prosperous colonies, so that the drone-producing powers of the colony may be regulated, that on signs of anything having gone wrong in the economy of the hive the bee-master may be able to detect the cause and to effect a remedy, and that the hive is so simple in construction as to be easily put together by any amateur joiner.

The frame known as the British standard, made of four bars of wood joined at the corners, is 14 inches long, 8½ inches deep, and is made of wood about ⅝ inch thick.

If one examines a skep in which the bees have been allowed to work at will, it is found that the combs are about an inch in thickness, and hang at a distance of about ½ inch from one another. Accordingly the frames are made ⅝ inch broad, and are hung at a distance of 1⅞ inch centre to centre. It has been found, however, that spacing the frames 1½ inch centre to centre during the summer months gives ample room for raising worker-brood, but prevents the overproduction of drones, and this spacing is much resorted to. The number of frames depends on the size of the swarm to be accommodated, on the prolificness of the queen, and the honey-yielding capabilities of the district. Ten or eleven frames are usually sufficient where an ordinary black queen is in use, but many bee-keepers use as many as fifteen for those of a more prolific race. A hive, then, containing ten frames must be 16 inches long, which will allow 1½ inch for two division-boards, 14½ inches broad (front to back), and 9 inches deep. A passage of ¼ inch is allowed at the ends of the frames, and ½ inch under the bottom bars of the frames. If more than this is given the bees will fill up the space with comb, and if less will be attached with propolis to the walls of

Fig. 6.—A Frame filled with Honey-comb.

Fig. 7.—Section of Frame-hive.

A, frame with brood-comb; B, walls of hive; C, floorboard; D, doorway; E, section of super for surplus honey; F, cover of hive; G, quilt.

the hive. The box thus constructed is the brood-chamber and storehouse of the bees, and is never despoiled of its sweets. It is necessary to provide accommodation for the storage of the surplus honey,

of which the bees are to be deprived. Bees in their wild state store the honey above the brood-combs; accordingly a box of corresponding dimensions is fitted above the hive, while the whole is protected by a sloping roof. A thick warm quilt is placed over the brood-frames in winter, and in the summer is removed and placed over the surplus box. A doorway is provided the full length of the hive and $\frac{3}{8}$ inch in height, and a suitable floorboard completes

Fig. 8.—Frame-hive with cover raised to show arrangement of frames.

the hive in its simplest form. Such a hive, however, is better to have further protection from extremes of heat and cold, and the one in general use consists of a light inner case to contain the brood-frames, placed in an outer case, both cases being made of wood $\frac{1}{2}$ inch thick. A 'lift' or 'eke' is also used for convenience in winter packing and to admit of two or three tiers of surplus sections being placed over the frames at the same time; otherwise too many swarms may result. Though the frames thus are hung at regular intervals, the bees would almost always work their combs irregularly on them, and the advantages of the frame-hive would be lost. To obviate this, guides are fixed to the under side of the top bar. A septum of wax, invented in 1857 and improved in 1876, is now inserted in the frame. This is known as 'comb-foundation,' and consists of a thin sheet of wax impressed in a machine on both sides with the form of the base of the cells. The bees take to this at once, and work combs of perfect regularity and flatness. The strips of foundation used may be of any breadth from $\frac{1}{4}$ inch to the full comb. By using full sheets the bee-master is able to control the birth of drones in the hive, for, if foundation bearing the impress of worker-cells be used, the comb will necessarily be capable of containing only worker-brood. The bee-keeper is thus enabled to assist nature in preserving the fittest by breeding drones from his best queens only, and, further, if full sheets are used the bees furnish their house in one-third the time it would otherwise take.

Quieting Bees.—Every one who has any knowledge of bees knows how rarely bees sting whilst swarming. This is owing to their being gorged with honey, when a bee will not sting unless hurt. If, then, the bees can be made to fill themselves with honey, they are in the bee-master's power. The general method of attaining this end is by blowing amongst them a little smoke. This may be done by a miniature bellows called the 'smoker,' in which a piece of cotton or other substance is kept smouldering and an occasional whiff of smoke used. A puff from a tobacco-pipe also serves the purpose. The bees, frightened by the smoke, seem

to fear that they are about to be driven from the hive, and they run to their store and gorge themselves, as they do preparatory to swarming, and in a minute they may be handled at will.

Swarming.—A pound weight of bees contains about 4500 individuals, and swarms usually weigh from 4 to 8 lb. A good stock during the summer, however, may contain 70,000 or 80,000 bees. In spring the number is much smaller, amounting to only a few thousands. As the season advances and becomes warmer and food more abundant, the queen deposits her eggs more and more rapidly, attaining in the height of the season a rate of 2000 to 3000 a day, and the colony soon becomes too numerous for the limits of their dwelling unless special room is provided. Swarming of the bees may be almost wholly prevented by providing sufficient accommodation and ventilation for the increasing numbers. In Scotland swarming rarely commences before the close of May, while in the south of England it is a few weeks earlier. The chief indications that a swarm is about to issue are the clustering of the bees at the entrance of the hive, and a cessation of the usual activity amongst the community. Previous to swarming, the bees gorge themselves with honey (this applies to a first swarm only) that they may have some store of provision for their new home. A first swarm will rarely leave the parent hive in bad weather. The time usually chosen is the early part of the forenoon, though a swarm has been known to come off as early as seven in the morning and as late as five o'clock in the afternoon. The bees pour from the hive in a constant stream. The swarm is not led forth by the queen, as is generally supposed, for she is sometimes seen to issue with the stragglers at the close. They fly round in circles until the whole have left the hive, filling the air with a pleasant hum. Gradually a knot of bees is seen to gather on some bush or tree close at hand, and this knot increases in size until the whole swarm has joined it. If left to themselves they will remain at rest for an hour or more, when they will again take wing and go off in a 'bee-line' to some chimney-top or decayed tree that has previously been decided on. As soon, however, as the cluster is complete the bee-keeper proceeds to skep the swarm, which he does by placing a straw-skep over it, and allowing the bees to crawl up of their own accord; or he may hold the skep under the cluster, and give the branch a sudden shake, when almost every bee will fall into the skep. He then shakes them into the frame-hive, which is either left till evening where the cluster has gathered, or is removed at once to its permanent station. Previous to swarming, the rearing of half-a-dozen or more queens has been commenced. Eight or ten days after the swarm issues the most advanced of these queens comes to maturity, and issues forth from her cell. Her first impulse is to destroy the remaining royal grubs. If the hive be of sufficient strength to swarm a second time, the worker bees keep guard over the cells, when the newly hatched queen takes flight with a second colony. Unless increase of stock is aimed at, second swarms should be avoided, and when they do emerge should be returned to the hive, after all the remaining queens or queen cells have been destroyed.

Artificial Swarming.—As has already been noticed, a swarm left hanging in its original cluster will go and establish a home for itself. The hives during the swarming season must therefore be carefully watched. To avoid the necessity of continually watching for swarms and the chance of losing them, as well as for other sufficient reasons, methods of artificial swarming are now practised by all advanced bee-keepers. This is a process easily accomplished, especially

with the movable frame-hive. An empty hive is placed on the site of the colony to be swarmed, which is itself moved aside. The frames of bees are then lifted out and examined one by one until the queen is found, when she, along with the bees and the frame, is placed in the empty hive on the original stand. One or two additional frames of brood and honey are placed along with it, and the hive filled up with frames in which full sheets of foundation have been inserted, and covered up as before. Empty frames also take the place of those removed from the old hive, which is taken to a new situation in the garden when the work is complete. The operation should not be gone about until the old hive is pack-full of bees, and if done about the middle of a fine day all the bees on wing during the operation, as well as all the old bees in the swarmed hive, will make their way to the new hive on the old site. The bees in the original hive will at once set about raising a new queen for themselves, but it is far better and more profitable to supply them the following day with a fertile queen. In the case of swarming from a straw-skep the simplest plan is, when it is quite full of bees, to place underneath it a hive containing old combs or frames filled with foundation, and cover all up as warmly as possible. Probably in a week the bees will be found working in the new hive, and if the frames are then examined and the queen found on them, the old skep may be removed to a new position. If a fertile queen is available and it be given to the old stock the following day, it will soon be in a condition that the operation may be repeated if increase is desired.

Feeding.—A stock should have at least 30 lb. of stores for winter use. All stocks should be examined in September, and any found deficient in stores rapidly fed up before the cold weather sets in. With a suitable feeder this may be accomplished in a few days. Syrup for winter food is made by bringing 6 lb. of sugar and 3 lb. of water to the boiling-point, and then adding a tablespoonful of vinegar to prevent the syrup from recrystallising in the combs. For spring use equal quantities of sugar and water may be used. Where feeding is necessary during winter or early spring a soft candy is used, and is made by bringing 10½ lb. of sugar and 3½ lb. of water to the boil, and then adding ½ oz. of cream of tartar and continuing to boil it until a temperature of 245° is reached. The mixture requires to be continually stirred until it begins to turn white, after which it is poured into moulds. Gentle feeding in late spring with syrup is often advisable, and cheap suitable feeders for the purpose are on sale.

Getting the Honey.—In olden times the invariable method pursued in this country of taking the honey was by allowing the bees to work at will in small straw-skeps until the close of the season, when they were destroyed by sulphur-fumes. This has almost everywhere now given place to a more humane method of management. A method adopted by advanced bee-keepers is what is known as 'extracting,' and is only possible in the movable comb hive. A box of equal dimensions to the body of the hive, and filled with frames usually 5½ inches deep, is placed over the brood-frames. The quilt is removed, and its place is taken by a sheet of 'excluder zinc'—viz. zinc with perforations large enough to allow the worker bees to pass freely through, but effectually bar the progress of the queen and drones. The upper story is thus kept free from brood, and the honey got is pure. When this box is full it is removed, and an empty one put in its place or underneath it. As soon as removed from the hive the capping of the cells is then cut off, and the frames are put into a machine known as the 'extractor.' This is a large cylinder containing

wirework cages that may be set in rapid rotatory motion. The centrifugal force throws out the honey, and the empty combs are replaced on the hive to be again filled by the bees. By this method of working the bees are saved the labour of comb-building, the large amount of honey required to form the comb, and large harvests of honey may be secured. As much as 400 lb. has been taken from a single stock during one season in this way. It should be noted that heather honey, being of a thicker consistency than flower honey, cannot be extracted in this way, but is taken from the comb by means of a 'heather-honey press.'

Another method is to fill the upper story of the hive with boxes of thin wood, known as 'sections,' placed side by side. The sections are usually made to contain 1 lb. of honey, and are fitted like the frames with guides of comb-foundation, which, however, is made much thinner than for the brood-frames. The advantage gained here over the old method of producing large supers is that the surplus chamber, like the hive, may be enlarged or contracted at will, and that the honey is secured in a more convenient and saleable form. To keep the bees in room and prevent too many swarms the plan usually adopted is to place a second box of sections under the first put on as soon as it is half-filled. The quantity of honey that may be taken from a hive differs with the locality as well as with the season and the strength of the colony. In a good season a populous colony may yield from 60 to 100 lb. of comb-honey, besides laying up a sufficient store to keep them through the winter, while if the extracting system be followed nearly double this amount may be secured.

The honey of various regions is flavoured by the flowers predominant in the districts where it is gathered—heather, white clover, fruit-blossoms, lime-tree, &c. In Scotland it is not unusual to transport the hives in the flowering season to the neighbourhood of heathery tracts. The honey most famous in the ancient world was that of Mount Hybla in Sicily and Mount Hymettus in Attica. Supplies are imported into Britain from various quarters; but it is to the United States and Canada that we must turn for bee-farming on the largest scale, and California, especially southern California, is the paradise of bee-keepers.

In 1913 there were said to be 10,000,000 hives in the United States, kept by 1,000,000 persons, of whom 6000 were professional bee-keepers. Some bee-keepers have from 2000 to 4000 hives, and as much as 400 lb. of honey has been obtained from a single hive. The most improved hives, honey-extractors, and appliances are in general use. See ADULTERATION, HONEY, WAX.

Beeberu. See GREENHEART.

Beech (*Fagus*) is an important genus of the natural order Fagaceæ, to which also belong the Oak (q.v.) and the Chestnut (q.v.). There is

only one species indigenous to Europe, the COMMON BEECH (*F. sylvaticus*), which has from time immemorial grown spontaneously on the chalk hills throughout southern and central England, but was only introduced into Scotland and Ireland early in the 18th century. It differs from oak and chestnut in having its female flowers in separate terminal bunches, in having male catkins with a long petiole hanging down from the side, and in having for its fruit a hard prickly involucre opening in four valves, and containing two or three three-cornered, sharply pointed nuts ('mast'). It is a tall tree, attaining a height of 90 to 100 feet, and a large girth when growing isolated in parks, and has a straight trunk with smooth gray-green bark and large densely foliated head. The leaves are ovate, glabrous, entire or obscurely toothed, pale green and ciliated along the edge while young, but afterwards becoming tougher and darker. The beech is indigenous to most of the temperate parts of Europe, and forms large forests in France, Germany, Austria, and the southern parts of Russia. In Scotland its northern limit of spontaneous growth is between 56° and 57°, but it extends to over 60° in Norway, and trends SE. across Europe. It is still the most characteristic tree in the woodlands on the Chilterns and the hills in Bucks, Berks, Dorset, Hants, and Wilts; but as a forest tree it attains its finest growth in Bucks. It grows well in Ireland, and thrives in all the central and southern parts of Scotland, especially near the sea-coast; it is therefore useful for shelter, but can only be expected to do well in a sheltered situation. As an ornamental tree it may grow to about 300 years, and as regards longevity ranks far behind oak, chestnut, or elm. Though shedding its leaves like other deciduous trees, yet if kept closely clipped as a hedge it retains the dead foliage throughout the winter. As a hedge it can easily be grown to a height of 10 to 12 feet, the highest and most celebrated beech-hedge in Britain being that at Meikleour, Perthshire. But it is as a forest tree that the beech is most useful. It is a shade-enduring tree, which can form close canopy in woods; and it is thus well suited for forming on suitable land the bulk of any timber-crop in which light-demanding trees, like oak, ash, larch, &c., are to be grown. And such a mixture has the further advantage that when the beech-leaves, which are comparatively rich in potash, fall and decompose, they form the very best kind of *humus* or vegetable mould, and help to enrich the soil. Hence a mixture of beech is of special value in oak-woods, such as the extensive woodlands in the Forest of Dean, Gloucestershire. The wood produced by the beech, although it was once classed as next to oak and ash in point of actual use in Britain, is now of no high general value as timber. It is brittle, short-grained, and not well suited to purposes demanding strength and durability, though durable when used in dry situations or entirely under water (mill and sluice work). Its chief use in England is for chair-making, an industry carried on largely for centuries back in and around High Wycombe (Bucks), but now mainly dependent for its raw material on imports of beech from the Continent. Other uses of beech-wood in Britain are for butchers' blocks, boot-trees and lasts, carpenters' planes, wooden bowls, and such articles. On the Continent it is of great importance as furnishing the best kind of domestic fuel and of charcoal, but is also largely used for railway-sleepers (after impregnation with creosote), wood-pavement, bent-wood furniture (Austria), parquet-flooring, carts, and agricultural implements. Beech-mast was formerly highly prized for the pannage of swine in England, and constant references to this are to be found in

Domesday-book. In central Europe the nuts are pressed to yield an oil, considered equal to olive-oil for cooking.

The customary Bucks way of regenerating the beech-woods is to make partial clearances every fifteen to twenty or thirty years, and to await a spontaneous crop of seedlings on a good mast recurring every five to seven years; and this is left to grow up till another partial fall of mature timber takes place. On the Continent a more systematic treatment is followed, the wood being divided into five or six blocks, in each of which in turn felling is continued for twenty years.

The chief varieties found in pleasure-grounds are the COPPER or PURPLE BEECH (*F. s. atropurpurea*), with dark-red or purplish-brown foliage, and the CUT-LEAF BEECH (*F. s. laciniata*), which are propagated by cuttings. The colour of the Copper Beech appears also in some degree in the narrower and longer leaves of the RED BEECH of North America (*F. ferruginea*), which forms extensive forests.—Two species of beech are found on the mountains of Java; four are natives of the more elevated parts of the south of New Zealand; several belong to the south of South America. The genus is, in fact, more characteristic of the colder latitudes of the southern than of the northern hemisphere. *F. Cunninghamii* is the 'myrtle-tree' of the mountains of Tasmania—a large tree with small, evergreen, leathery, serrate leaves. The evergreen beech of Tierra del Fuego (*F. betuloides*) forms forests whose dark-green foliage contrasts strikingly in winter with the dazzling snow. *F. antarctica* ascends higher on the mountains about the Strait of Magellan. *F. procera* grows and attains a majestic size in the Andes of Chile. In Australia the name is applied to trees of many other genera. The Black Beech is a *Cryptocarya*, the Queensland Beech a *Gmelina*, the Native Beech a *Callioma*.

Beech-drops. See CANCER ROOT.

Beecher, one of the most remarkable families that America has produced since the settlement of the continent. Its founder was one of the original colonists who settled in 1638 at New Haven, Connecticut; and there LYMAN BEECHER, an eminent divine, was born on the 12th October 1775. He graduated at Yale College in 1797, and became a Presbyterian minister. He preached at East Hampton, on Long Island, from 1798 till 1810; at Litchfield, Connecticut, from 1810 till 1826; and in the latter year was called to a pulpit in Boston, with the avowed purpose of counteracting the growth of Unitarianism, which, under the influence of Channing and others, was then rapidly advancing. Of an energetic and positive character, Beecher was always among the foremost to combat what he considered the evils of his time. As early as 1806 he attacked the practice of duelling, in a sermon suggested by the killing of Alexander Hamilton by Aaron Burr, and he laboured earnestly in the cause of temperance in the early days of that reform. In 1832 he became president of Lane Theological Seminary, near Cincinnati, Ohio, a position which he held for twenty years. Though a professed Calvinist, he was arraigned for heresy by the extremists of his faith, but was acquitted by the presbytery, and thenceforth was a recognised new school leader in the controversy which rent the Presbyterian Church into old school and new school factions. He resigned the presidency of the seminary in 1852, and died January 10, 1863. In 1864 was published his autobiography and correspondence, edited by his son. Mr Beecher was the father of thirteen children—seven sons (all of whom became clergymen) and six daughters.

CATHERINE ESTHER, the eldest child of the family, was born at East Hampton, on Long Island, September 6, 1800. In early life she became engaged to a Professor Fisher, of Yale College, who was lost by shipwreck, and she never married. From 1822 to 1832 she was principal of a seminary in Hartford, Connecticut, and subsequently devoted her energies and her pen to the advancement of female education. She wrote numerous volumes, principally relative to the needs and duties of women. She died May 12, 1878.

HARRIET ELIZABETH (Mrs Harriet Beecher Stowe), author of *Uncle Tom's Cabin*, was born in Litchfield, Connecticut, June 14, 1811. In her childhood she received careful training both at home and at the academy of her native village, and she early developed a fondness for writing—often upon the most abstruse subjects—that amounted almost to a passion. It is recorded that when twelve years of age, at an annual exhibition of the academy, she surprised her friends by the production of an essay on the negative side of the question, 'Can the Immortality of the Soul be proved by the Light of Nature?' On leaving the academy she joined her sister Catherine at her school in Hartford—first as pupil and afterwards as teacher. There she remained until the appointment of their father to the presidency of Lane Theological Seminary, when the two daughters established a school at Cincinnati, Ohio, adjoining the slave-state of Kentucky. Here Harriet saw much of the practical workings of the institution of slavery, and became acquainted with many of those scenes and incidents which she afterwards so graphically described in her anti-slavery writings.

In 1836 she married the Rev. C. E. Stowe, a theological professor in Lane Seminary, with whom she subsequently removed to Brunswick, Maine, and in 1849 she issued her first work, *The Mayflower, or Sketches of the Descendants of the Pilgrims*. In 1851 she engaged to contribute a story to *The National Era*, a Washington anti-slavery paper. This was *Uncle Tom's Cabin*, by far the most notable novel till then published in America; over 150,000 copies were at once sold in the United States, and in Britain over 1,000,000 copies were disposed of in a twelvemonth. Despite the pope's prohibition, it was eagerly read in all Continental countries. It appealed to all abolitionists and haters of slavery, as also to multitudes of strict Puritans who suspected all novels, and disliked mere tales of love and romance. The author's ardent sincerity speaks from every page—her genuine loathing of cruelty, her indignation at oppression, and her scorn of the sophistry by which slavery was defended. *Uncle Tom* and her next story, *Dred, a Tale of the Dismal Swamp*, as pamphlets with a tendency, accomplished vastly more than Dickens. Lincoln not unjustly described their author as 'the little woman who made the war.' Modern readers are more apt to note the diffuseness, exaggeration, and unction of these famous books, and accordingly to find them not a little tiresome. Her later works expose more fully her defects as an artist—*The Minister's Wooing* (1859); *The Pearl of Orr's Island* (1862); *Agnes of Sorrento* (1862); *Oldtown Folks* (1869); *My Wife and I* (1871); *Pogonuc People* (1878), &c. As for her charge against Byron's morals (supported later by members of his family) in *Lady Byron Vindicated* (1870), it may be said that she was mainly moved by her profound conviction that the story she told was true, and that it justified a misjudged wife. She outlived her fame, and is remembered rather as a great missionary than as a great writer. Her last years were darkened by family troubles, heavy financial losses through the war, and the clouding

of her mental powers. She died at Hartford, Conn., 1st July 1896. See the *Life*, compiled from her letters and journals, by her son in 1890, and another by her son and grandson in 1911.

HENRY WARD BEECHER, born at Litchfield, Conn., 24th June 1813, graduated at Amherst College, Massachusetts, and as pastor at Indianapolis was identified with the abolition movement, in his sermons depicting the horrors of slavery in the United States. In 1847, on the organisation of Plymouth (Congregational) Church, in Brooklyn, New York, he accepted the pastorate, and practically ignoring formal creeds, announced his determination to preach the gospel of Christ, and to do battle in the causes of temperance and anti-slavery. An immense congregation was attracted by his ministrations, and during his subsequent career of forty years (less a few months) he laboured in this chosen field with an almost unparalleled earnestness. He aided in establishing *The Independent*, a politico-religious journal, to which he was for nearly twenty years a prominent contributor. He favoured the free-soil party in the presidential campaign of 1852, and denounced the repeal of the Missouri Compromise (1854); and in the contention which followed between the pro-slavery and anti-slavery factions in the settlement of the territory of Kansas, he openly counselled the meeting of force with force if necessary in the protection of the Free State settlers in their rights. He was an ardent supporter of the republican candidates in the presidential contests of 1856 and 1860, and on the breaking out of the civil war, his church raised and equipped a regiment of volunteer soldiers for service in the field. Some rest to his overtaxed powers becoming necessary, he visited Europe in 1863, and on his return to England from the Continent, he delivered addresses on the condition of his country to crowded meetings, often of unsympathetic auditors; and it is not unreasonably claimed by his friends that he did much at this time towards convincing the British public that his government would ultimately triumph. On the close of the war in 1865, Mr Beecher became an earnest advocate of reconciliation between the two sections on the broadest ground of charity and goodwill. He even alienated, by his liberal course, many of his former political friends, among others the editor of *The Independent*; and his connection with that journal ceased. Later (1870) he assumed the editorship of *The Christian Union*, the circulation of which increased in one year from 3000 copies weekly to over 30,000. Of the charge of adultery with a member of his church, preferred against him in 1875, it is enough to say that one trial resulted in the disagreement of the jury; whilst another before an ecclesiastical council was decided in Beecher's favour. The decade of active usefulness which followed served to restore to the great preacher a large measure of public confidence and esteem. He visited Great Britain in the summer of 1886, delivering numerous addresses, and on his return resumed his pastoral duties, in the active discharge of which he died of apoplexy, March 8, 1887.

Of his published writings, the principal are *Star Papers* (1855), first published in *The Independent*; *New Star Papers* (1858), republished under the title of *Summer in the Soul*; *Thoughts as they Occur*, contributed to the *New York Ledger*, and republished, under the title of *Eyes and Ears* (1864); *Lectures to Young Men* (1844; revised ed. 1850); *Aids to Prayer* (1864); *Norwood, or Village Life in New England* (1867); *Lecture-room Talks* (1870); *Yale Lectures on Preaching* (3 vols. 1872-74); *The Life of Jesus the Christ* (2 volumes, 1871-91), &c., besides many separate sermons and addresses. See his *Life*, by Joseph Howard, jun.

(1887), that by Scoville (1888), and his *Autobiographical Reminiscences* (ed. by Ellinwood, 1898).

Beechey, SIR WILLIAM, R.A., born at Burford, Oxfordshire, in 1753, entered the Royal Academy as a student in 1772, and devoted himself chiefly to portrait-painting. In 1793 he was elected an associate of the Royal Academy; and in 1798 he received the honour of knighthood, and was made a Royal Academician, for his picture of the Cavalry Review in Hyde Park by George III., which is reckoned his best work. Beechey now received the patronage of the royal family and court. Among his portraits are those of Lord Nelson, Sir William Hamilton, Lord St Vincent, Lord Cornwallis, John Kemble, and Mrs Siddons. Beechey was not a painter of the first rank, but his portraits are generally characterised by easy attitude and naturalness of expression. He died at Hampstead, 28th January 1839.—His son, FREDERICK WILLIAM, born in London in 1796, entered the navy at the age of ten. In 1818 he took part under Franklin in a scientific voyage of polar discovery; and the services he rendered with his pencil during this voyage gained a grant of £200 from parliament. In 1819 he was engaged in another arctic expedition under Parry; and in 1821 rendered further important services to science by his exploration of part of the north coast of Africa, of which the results were published in 1828. In 1825 he received a commission to proceed by the Pacific Ocean and Behring Strait to the Polar Sea, in order to communicate, if possible, with Franklin, who was to make the journey overland from North America. The explorers did not meet, although at one time they were within 150 miles of each other. Beechey returned in 1828. He died Rear-admiral of the Blue, 29th November 1856. See his *Voyage of Discovery towards the North Pole* (1843).

Beechworth, chief town of the Murray district in Victoria, and of a considerable goldfield, 170 miles NE. of Melbourne; pop. 3000.

Bee-eater (*Meropidæ*), a family of birds nearly allied to kingfishers. Numerous forms occur, widely distributed in Africa, India, Moluccas, and Australia, and are well known for their bee-eating propensities and bright plumage. The Common Bee-eater (*Merops apus*) very rarely occurs in Britain,

Common Bee-eater (*Merops apus*).

but is an exceedingly abundant summer visitor in Southern Europe. Even Aristotle speaks of its ravages among the bees, which the bird seizes on its swallow-like flight, or by watching beside the hives. They excavate long holes which honeycomb the banks of rivers like the Don and Volga.

These nests are sometimes 10 feet deep, and the wearing away of the rather long bill testifies to the amount of labour which they expend to secure the safety of the young. These are often seen sunning themselves at the openings of the holes, tumbling back when alarmed by the approach of reptilian or other enemies. When the flowers wither and the bees cease to work, the birds migrate southwards, and breed again in Africa, where Livingstone has described their excavations on the banks of the Leeba. Their bright, predominantly green plumage is often used to decorate ladies' hats, and they have further some practical importance on account of their destructiveness to bees, which is compensated to some extent, however, by their ravages among wasps and other insects. The Hottentots watch their flight in order to find the bee-nests.

Beef. See CATTLE, FOOD.

Beef-eater (*Buphaga*), a small genus of African perching birds, nearly related to the starlings. The name Ox-pecker is more accurately descriptive of their habit of feeding on the larvæ of gadflies and the like, which they find on the backs of cattle, camels, rhinoceroses, and other large animals. Livingstone notes how the sharp eyesight of the South African Buffalo Birds (*B. africana*) make them useful sentinels to the cattle herds, and the same has been observed in regard to the rhinoceros. Their habit of devouring the insect pests, which they generally do without irritation to the infested animals, is evidently convenient and pleasant both for themselves and the cattle.

Beef-eater, a term now applied jocularly to certain functionaries belonging to the Yeomen of the Guard (q.v.), who, ever since the time of Henry VII., at whose coronation they made their first appearance, 30th October 1485, have formed part of the train of royalty, attending the sovereign at royal banquets and other state occasions. The Tower Warders are a distinct corps from the Yeomen of the Guard, and had their origin in the reign of Edward VI., when fifteen of the Warders were sworn in as Extraordinary Yeomen of the Chamber. They received liveries like the Yeoman of the Guard in ordinary, but are distinguished from them by the absence of the cross-belt. The costume has varied somewhat during the four centuries; a slight alteration was made in 1858; and in 1885 a cloth hat was given to be worn with the undress uniform of the Tower Warders. Their costume has had much to do with their attractiveness to sight-seers. The word has of late been usually regarded as a corruption of *buffetier* (Fr.), or *beaufetier*, one who attends the buffet or sideboard. It would thus be an instance of what Latham calls 'foreign words simulating a vernacular origin;' like *sparrow-grass* for *asparagus*, ancient for *ensign*. But Skeat holds that *beef-eater* is simply *eater of beef*, a servant or dependant, and quotes *eaters* (from Ben Jonson) and *powder-beef lubbers* used in a similar sense. See T. Preston's *Yeomen of the Guard* (2d ed. 1887).

Beef-tea is a light and pleasant article of diet. It is best made as follows: A pound of lean beef is cut into small pieces and placed in a closed jar with a pint of cold water; after an hour the jar is allowed to stand for another hour in a pan of gently boiling water; the contents are then strained through a coarse sieve. Beef-essence may be made by placing the meat in a jar with two tablespoonfuls of water and simmering it as above for two or three hours, when three or four tablespoonfuls of thick fluid can be pressed out. Salt is then added according to taste. Either process removes from the meat almost all its salts and extractive matters, with a proportion of its albumen and gelatine.

Beef-tea is popularly supposed to contain all the nourishment of the meat from which it is made. This is a great mistake; for though the substances which give the beef its flavour are extracted, far the larger part of the nutritious albumen and gelatine remain in the tasteless and hardly digestible residue: more complex processes are required to obtain highly nutritious extracts from meat. It is, however, of great value in the treatment of invalids, for the nutritious elements which it does contain are, so far as they go, in a digestible form; it is, moreover, a pleasant stimulant, a relish which may enable a sick person with poor appetite to eat other food with enjoyment, and a suitable vehicle for the administration of more nutritious material, for example, some of the easily absorbed 'peptones' or 'infants' foods' in the market. It must always be borne in mind that beef-tea alone has not a high value as a food, and that the increased sense of strength and well-being often following its administration is due to a stimulating more than to a nourishing effect, and is therefore transient and sometimes harmful. Moreover, in some diseases, particularly gout and kidney-disease, it is usually injurious. Mutton, treated in a similar manner, yields a broth or tea which is not so easily digested, and is hurtful to persons of weak stomach, especially if the fat be not skimmed off from the liquid. A knuckle of veal affords a similar broth or tea; but it is not so light as beef-tea, and, moreover, gelatinises on cooling. A broth or tea prepared from a young chicken is, of all decoctions of animal matter, the most readily digested, and is specially suitable for invalids, where great irritability of the stomach exists.

Beef-wood. See CASUARINA.

Beehive Houses. The beehive plan of construction is a primitive method of throwing a roof of dry-stone masonry over a chamber of the same. In building with hewn stones and mortar, a stone-roofed chamber would be vaulted on the principle of the arch; but in primitive building with undressed stones and without mortar, the method was adopted of setting inward each successive course of the upper part of the side walls, until the space to be

in the chambered cairns or barrows of Britain and Ireland; and as these have been shown by their contents to belong to the stone age, it is therefore the earliest method of constructing a roof of which we have extant evidence in the British Isles. It is also the usual style of the basement chambers of the Brochs, or so-called 'Pictish towers' of Scotland, which belong to the iron age. In the early Christian period, many of the small churches and oratories of the Celtic Church in Scotland and Ireland were still constructed in the same primitive manner; and the dwellings of the monks in early Celtic monasteries have been termed 'beehive houses,' from their being almost invariably built of dry stone and roofed in this manner. In some districts of Ireland, as in Kerry, the remains of beehive houses, called by the country-people *cloghams*, are still abundant. They are not connected with ecclesiastical sites, but seem to have been the common dwellings of the inhabitants at some time probably not extremely remote, but now unknown. O'Flaheerty, mentioning the *cloghams* of West Connaught in 1684, describes them as buildings of stone, brought to a roof without any manner of mortar to cement them, some of which would hold forty men on their floor, and which were so ancient that nobody knew how long ago any of them were made. In the Western Isles of Scotland there are many remains of beehive houses of quite recent date. Captain Thomas saw forty or fifty in a limited area of the island of Lewis in 1857; and Sir A. Mitchell recorded in 1880 that not more than from twenty to thirty were then inhabited. These, however, were not the permanent dwellings of the people, but the huts of their summer shielings, erected usually on grassy spots in the glens to which they proceed with their cattle, and remain making butter and cheese in July and August, 'during which time,' says Captain Thomas, 'they dwell in these circular stone-roofed houses called *bothan*, or in timber-roofed ones called *airidhena*.' The *bothan* are seldom larger than 10 feet in diameter; a row of stones is placed across the interior for a seat, on one side of which is the fire, and on the other the sleeping-place. Many of the older ones, however, have several chambers, each with its beehive roof. Huts of beehive shape, but of light materials, are used by various savage peoples.

Beehive Tombs, domed tombs of the Mycenaean culture, such as the 'Treasury of Atreus' and others at Mycenæ (q.v.) itself, and those at Orchomenos and Vaphio. Sometimes they have been formed by excavation.

Bee-kite. See HONEY BUZZARD.

Beelzebub ('god of flies'), the form of Baal worshipped by the Philistines at Ekron. The Greeks also had Zeus 'Apomyios' or 'Myiagros' ('dispenser of flies'), doubtless a god of flocks and herds. As the heathen deities were all regarded as demons by the Jews, the name Beelzebub became, in course of time, commonly applied to the chief of evil spirits, and in this sense it is employed in the Gospels. The New Testament reading *Beelzebub* is variously explained; see BAAL.

Beer (Fr. *bière*, Ger. *Bier*) is a beverage prepared from grain (usually barley) which is malted or otherwise prepared, ground, and infused with hot water; the extract is drawn off, boiled with hops, cooled, and fermented. It is prepared with varying quantities and qualities of the materials, and the resultant drink differs so greatly as to be known by the different names of strong ale, pale ale, bitter ale, mild ale, small beer, stout, porter, lager beer, &c. Beverages resembling beer have been brewed from the most ancient times. Herodotus states that the Egyptians prepared such a drink, and in the 1st century Tacitus states that it

(From a Photograph by Lord Dunraven.)

spanned was so reduced that it could be covered in by a single stone, or by several stones laid lintel-wise, side by side. This method of constructing a stone roof is found in many varieties of prehistoric structures. It is the usual style of roofing the chambers

was the common drink in Germany. Pliny states that it was prepared in Gaul under the name *cerevisia*, and in Spain as *cerua* (*ceres*). We do not know when beer was first introduced into Britain, but it was in common use in the reign of Edward the Confessor, and the frequent mention of it in the national records shows that it has continued so up to the present day. Ale and beer seem originally to have been synonymous; both words (*A.S. alu, ealu; béor*) were in use before the Norman Conquest. *Beer* occurs in Old English but rarely save in poetry, and did not become common till the 16th century, when, hops having been introduced into England, the word meant hopped malt liquor as distinguished from ale (unhopped). The brewer for sale existed in 1492, but until the end of the 18th century domestic brewing was as common as domestic baking. To-day the beer of the nation is almost entirely the product of a few large breweries, where the most suitable materials are employed under careful scientific direction, utilising the best apparatus, in order to turn out the brilliant, sparkling, and pleasant-flavoured article a critical taste demands.

The most important materials are water, malt, and hops. In some beers a portion of the malt is replaced by sugar, or raw or prepared grain, or a combination of these; and in a few cases a portion of the hops is replaced by other flavouring material. Roasted malt gives colour and flavour to stout and porter, and isinglass is used to assist in fining beer.

Water used in brewing is usually obtained from wells or springs; though rain, river, or lake water may be employed if free from sewage or other contamination. As a general rule water suitable for drinking is also suitable for brewing, but particular kinds of potable waters are especially adapted to the preparation of the many varieties of beer. The soft Dublin water has materially contributed to the fame of Dublin stout, and the hard gypseous water of Burton-on-Trent to that of the well-known pale, strong, and export ales of that town. It is quite usual for brewers to treat the natural water with salts in order to imitate natural waters of proved brewing suitability.

Malt is prepared from Barley (q.v.)—very rarely other grain—and only in the cooler portion of the year, as the process cannot be successfully controlled in warm weather. The most important qualities which the maltster requires of the barley are that it should be ripe, and that he should receive it uninjured by the various processes and conditions to which it has been exposed. Experience has also shown that barley from special districts and of special varieties has advantages over other barleys for the preparation of malt suitable for the different kinds of beer. Maltings, the buildings in which barley is converted into malt, consist essentially of two portions: the growing-floors on which germination takes place, and the kilns on which the germinated barley is dried. A steeping-cistern is placed on the growing-floor, and there are usually malt and barley stores, and machinery for cleaning barley and malt and moving the grain. The barley, on arrival at the maltings, is usually screened to remove broken corns, other grain and dirt, and often dried on a kiln; this increases the regularity of germination. The barley is then steeped in cold water in brick or iron cisterns for two or three days, the water being changed several times. At the termination of the steep, the grain, which is now quite soft, is thrown out of the cistern in a heap, called the couch. Germination at once begins, and is soon apparent by the chitting of the corns, a rise of temperature, and the emission of carbonic acid gas. The couch is now broken down, and the grain spread on the growing-floor of the malt-house. The floor is

usually of cement or tiles. The object of the maltster is now so to control the germination of the grain that at the end of about ten days he will have the grain so mellowed by the germination changes that its Starch (q.v.) will be readily soluble in the mashing process, without at the same time suffering an undue loss by respiration or becoming damaged by the growth of mould or other organism. This he effects as circumstances indicate: by opening the windows and spreading the grain over a greater area of floor, and thus reducing its temperature; by allowing the heat of germination to warm it by the converse procedure, or by moistening it, or allowing it to dry. The particular treatment required can only be decided after much practical experience. The germination having thus been guided to the right extent, the grain will be found to have acquired several bushy rootlets, and the acrospire or shoot to have grown up under the palæ or outer skins about two-thirds to three-quarters the length of the grain. It is now ready to be dried on the kiln. The drying-floor is usually composed of perforated tiles, and under it are placed one or more fires of coke or anthracite. Over the drying-floor the roof is furnished with cowls or louvres, which can be opened or shut as required. In the United Kingdom it is not usual to have more than one drying-floor in a kiln, but sometimes a second one is placed above. It is also usual in this country to dry the malt by passing the products of combustion of the coke or coal directly through the grain; but, again, in some kilns the malt is dried by hot air which has been heated by passing in pipes through the furnaces. The germinated grain, being loaded upon the kiln-floor, is slowly dried by the passage through it of large quantities of hot air for two or three days. Towards the end of the time the volume of air passing through is decreased, and the temperature allowed to rise to about 200° F. This latter stage of the drying is called curing, and during it the grain acquires the desired biscuity flavour. The dry malt is then thrown off the kiln and the rootlets (malt culms) removed. When cold the malt is stored in bins until required.

Hops (*Humulus lupulus*) were known to the ancient Greeks, and are described by Pliny as *lupulus*, an appetiser and salad. Their use in brewing beer appears to date from at least the 8th century, as in 768 a hop-garden is mentioned as given to the monastery of St Denis, and it is difficult to see for what other purpose hops would be extensively grown. In 1364 an enactment was made in Germany concerning hopped beer, so that the use of hops appears to have been common at that time. Hops, however, do not appear to have been used by English brewers before 1492; and although both Henry VII. and Henry VIII. forbade their use, Edward VI. allowed them, and they have since continued in use. The hop used in brewing is the fruit, or strobile, of the plant. This somewhat resembles a fir-cone, and consists of a stem or strig, with a number of short branches arranged alternately along its opposite sides. On each of these branches grow leaf-like structures called bracteoles, which carry at their base the seeds. In addition to these are similar bracts which do not bear seeds. On both these kinds of bracts are the lupulin glands containing the oils and resins on which depend the flavouring and preservative power of the hop. There are many varieties of hop, distinguished by the shape of the cone, the shape of the bracts and strig, &c. The cones are picked when ripe, and dried, usually on a kiln over an open fire, and often bleached with the fumes of burnt sulphur. The dried hops are compressed into canvas bags, and stored in a cool and

dry place until required. Hops give to the beer that pleasant, bitter, and aromatic flavour which distinguishes it from other alcoholic beverages. During the boiling process they assist in the precipitation of insoluble matter, and in the clarification of the brew. The resin of the hop constitutes the chief preservative of the beer. The bitter of the hop has the important property of being transient, the bitter quickly leaving the palate; most vegetable bitters are persistent. Hops possess distinctly narcotic properties.

The world's hop-crop varies much from year to year; the average is about 1½ million cwt. The following are the figures for 1911:

	Cwt.	Acres
Bavaria	120,000	43,437
Rest of Germany .. .	107,000	28,272
Austria .. .	184,000	52,310
England .. .	238,000	33,050
United States of America .. .	390,000	46,250
Other countries .. .	145,000	36,395
	1,274,000	284,714

The following is the official estimate of the English crop of 1914:

	Cwt.	Acres
Kent	313,704	22,626
Hants, Surrey, and Sussex .. .	74,430	5,201
Hereford, Worcester, Gloucester, and Salop .. .	114,124	8,834
	507,258	36,661

The average yield per acre, 13·8 cwt., in England—hops are not grown in Scotland or Ireland—in 1914 exceeds the average of the preceding ten years by 4 cwt.; the consumption of hops in the United Kingdom in 1914 was 559,424 cwt.; the balance required had to be imported. Exigencies of the war caused a reduction of the English hop acreage, and the crop of 1918 was only 130,272 cwt., whereas double this amount was used.

Sugar used in brewing is usually glucose, cane sugar, or invert sugar (see article SUGAR).

Raw grain is usually either maize, rice, or barley; which are also used after previous preparation to render their starch soluble in the mash-tun.

Breweries consist essentially of two parts, the brew-house, in which the preparation of the extract of the malt (wort) takes place, and the tun-house, in which the fermentation of the wort takes place. There must of course also be subsidiary buildings for the cleansing of the casks, the storing of the materials and the finished article, &c. The process of brewing commences with the grinding or crushing of the malt, usually between two iron rollers. The crushed malt is stored in hoppers placed over the mash-tuns. The mash-tuns are circular vessels of iron or wood fitted with (1) draw-off pipes in the bottom, (2) a false bottom of perforated plates to prevent the insoluble portion of the malt from getting into these pipes, (3) a sprinkler or sparger for distributing hot water on the surface of the goods, and (4) machinery for thoroughly mixing the malt and water. The ground malt and hot water are either mixed together as they fall into the tun, or water of the requisite temperature and amount is first introduced, and the malt allowed to fall into this and well mixed by revolving rakes. The action of hot water on the malt causes a number of chemical changes, the most important of which is the conversion of the starch, by the action of diastase, into maltose and dextrin. Other ferments are also present and act, amongst which is a proteolytic one. These changes are materially affected by the temperature, and experience has shown that 150° F. or thereabouts is the most suitable for the preparation of a wort for brewing beer. The mixture (the mash) is allowed to stand for a couple of hours, and then the taps under the mash-tun are opened and the extract run off into the coppers. The residue remaining in the

tun is then extracted by sprinkling on the surface hot water until all the soluble matter is washed out from the draff, which is called 'brewers' grains,' and is used for cattle-feeding. This method of preparing the wort—the one commonly employed in the United Kingdom—is known as the 'infusion method.' A modification known as the 'decoction method' is usually employed in the preparation of lager beer. In this about one-third of the mash is pumped into a special boiler called the mash-copper, and in this it is boiled for a short time, and then returned to and mixed with the remainder of the mash in the mash-tun; again a third of the mash is pumped into the mash-copper and boiled, and again returned to the mash-tun and this process again repeated. The process of extraction then proceeds as in the infusion method. The wort, however prepared, is next boiled with hops in the wort-coppers. These are, as their name indicates, copper vessels heated either by furnaces or by steam. The average weight of hops per barrel used by British brewers is 1·85 lb. The two other chief beer-producing countries, Germany and the United States of America, use only about half this weight of hops per barrel of beer brewed. A greater weight of hops per barrel is used in the preparation of bitter ales than of mild ales of the same strength, and a still greater weight of hops in the preparation of ales that are to be kept for some time as strong ales and export ales. After some hours' boiling, the wort is run into the hop-back, which is a vessel containing a false bottom for straining the hops from the wort. The boiling has caused (1) a certain amount of concentration, (2) the precipitation of some of the constituents of the wort, and (3) the acquisition of the bitter flavour of the hop. The clear wort runs from the hop-back on to the cooler. This is a large, shallow vessel on which a certain amount of cooling of the wort takes place, and also the precipitation of some of the wort constituents; from the cooler the wort passes through the refrigerator, in which it meets a current of cold water contained in thin walled tubing, and by which it is cooled to a temperature suitable for the commencement of fermentation. Before the invention of refrigerators the whole of the cooling had to take place on the cooler, but ever since the introduction of these appliances the tendency has been to diminish both the size of the cooler and the time the worts lie on it. At present most of the cooling is done on the refrigerator. Some brewers have even ceased to use coolers, but this is not yet the common practice. The cooled wort is run from the refrigerators into suitable vessels, usually of wood, either round or rectangular, and the yeast added to start the fermentation. The worts for the preparation of British pre-war beers average in specific gravity 1053, and contain in 100 parts about 13 parts of solid matter. In a wort prepared from malt and hops alone, about two-thirds of this would be fermentable sugars and one-third of it unfermentable carbohydrates, nitrogenous matter, and mineral matter. Fermentation at once begins, and outward signs of it soon appear in the shape of a creamy head (caused by the evolution of carbon dioxide) and a rise of temperature (due to the heat evolved by the chemical reaction). The Fermentation (q.v.) consists mainly in the decomposition of the sugars of the wort into approximately equal quantities of alcohol and carbon dioxide. Owing to the facts that (a) a solution of sugar in water is heavier than water, (b) a solution of alcohol in water is lighter than water, and (c) that most of the carbon dioxide produced escapes as gas, there is a continuous decrease in the specific gravity of the wort as the fermentation proceeds; this affords the brewer a convenient means of watching the fer-

mentation. The specific gravity of the fermenting wort is called its attenuation.

So far the methods of all brewers (except the modifications of the mashing process above described) are very similar; but the fermentation is carried out very differently by brewers of the various varieties of beer, and so it is necessary to describe each process separately. The brewer of ale and stout uses a top or high-fermentation yeast—i.e. one that rises to the top of the fermenting liquid towards the end of the fermentation. The worts are pitched—that is, the yeast is added—at about a temperature of 60° F. By suitable cooling means the temperature is controlled, and usually not allowed to rise above 70° F. Towards the end of the fermentation the yeast rises to the surface, and must be promptly removed or the beer will acquire a coarse, yeasty flavour. This removal is effected in various ways; the simplest, and probably oldest, is to fill casks with the fermenting wort, and allow the yeast to work out through the bung-hole, the wastage as it arises being made good by fresh beer. The Burton Union system is a direct development of this. In this system a row of casks each holding about 150 gallons, supported on their sides and bung-hole uppermost, are connected together by a pipe. In the bung-hole of each fits a swan-neck-shaped metal pipe which overhangs a trough (the yeast-trough) placed over the casks. There is usually a row of casks on each side of the yeast-trough. At the end of this 'Union set,' as it is termed, is a smaller cross trough (the feeder) at a level intermediate between that of the yeast-trough and the casks, and connected with the yeast-trough on the one side and on the other with the pipe uniting the row of casks. The casks and a part of the yeast-trough and feeder are filled with wort which has commenced its fermentation in another vessel; the gas produced by the fermentation forces a part of the liquid as a froth up the swan necks into the yeast-trough. The beer separating from this passes back through the feeder into the casks; this circulation continues as long as the fermentation continues. Shortly before the end of the fermentation the yeast rises, and, accompanied by some beer, passes through the swan necks. The yeast collects in the yeast-trough, and the beer separating passes back through the feeder into the casks. At the end of the fermentation the casks are full of beer and the yeast is all in the yeast-trough. The Skimming system is another method for separating the yeast from the beer. In its simplest form, the yeast is simply skimmed off as it rises to the surface; it is usual, however, to save this labour by having fixed in the fermenting vessel pipes with openings adjustable to the correct level, so that as the yeast rises it flows through these to a vessel below. These two methods for removing the yeast from the beer result in an article which varies somewhat, and local brewers make use of modifications to produce a beer suited to the local taste. After the separation of the yeast (this is never quite complete) the beer is racked into the carriage-casks, a handful of hops being usually added, and the bung inserted and hammered tight. The beer-casks in general use in the United Kingdom are butt=108 gallons, hogshead=54 gallons, barrel=36 gallons, kilderkin=18 gallons, firkin=9 gallons, and pin=4½ gallons. They are usually made of Baltic oak, with wrought-iron hoops. Stout is often placed in large vats for some time before it is racked into the carriage-casks. As the fermentation is purposely never quite completed in the brewery, it continues slowly in the cask, and in a week or so sufficient carbonic acid gas has been produced to make the beer fresh or 'in condition'; it is then ready for consumption, a little isinglass finings being usually added to facili-

tate brightening. Some beers, such as export and strong ales, require a much longer period of time to mature, extending in some cases to years.

Beer for bottling is allowed to fall quite bright in cask and then bottled; after a month or so in bottle it will develop the well-known flavour and condition of bottled beer, which is caused by a fermentation in bottle, a sediment being at the same time thrown out. Although, from the nature of the case, it is impossible to mature beer in bottle without the production of some sediment, yet it has been found possible to mature beer in cask or large tanks, and then transfer it to bottle without loss of condition; this product, although wanting the piquancy of beer matured in bottle, has yet, from its obvious advantages, achieved a certain vogue. Such a bottled beer is prepared by taking a newly racked beer and highly charging it with carbonic acid gas, either by pumping in this gas or by the fermentation of sugar added or naturally existing in the beer. The beer, when charged with gas under considerable pressure, is cooled to near the freezing-point, and at once, or after some days at this temperature, forced through a filter into the bottles. The bottles are at once tightly closed to prevent loss of gas. Such beer will remain brilliant for some time, and at ordinary temperatures shows a strong effervescence.

Lager beer appears to have been first made in Weihenstephan, a Bavarian abbey, towards the end of the 15th century. It was not, however, until the end of the 18th century that lager beer began to occupy a predominating position in the German beer trade. The general popularity of the beers of Bavaria and Bohemia spread through Germany and Austria, until now only a few local types of high-fermentation beer are brewed in these countries. In the United States of America, where brewers were largely of German origin, the methods were chiefly German. At the present time in Germany only malt, hops, and water are allowed to be used for brewing lager beer. The brewer of lager beer employs a yeast which falls to the bottom towards the end of the fermentation; hence the term bottom or low fermentation. The worts are pitched at about 40° F. The main fermentation takes about ten days, the temperature of the fermenting liquid being prevented from rising by suitable cooling devices. At the end of the principal fermentation the beer is run from the fermenting vessels, leaving the yeast at the bottom of these, into large store casks, called lager-casks, which are kept in a cellar at about the freezing-point. Here the ale matures for some months, being kept charged with gas by a slow continuation of the fermentation, and it is ultimately racked off into small casks for immediate consumption, or bottled. If the bottled ale has to be kept, it is pasteurised by heat. The table shows the composition of various beers:

	Percentage of Extract in the Wort before Fermentation.	Percentage of Extract in the Beer.	Percentage of Alcohol in the Beer.
Pale ale	16.0	4.0	6.0
Extra stout	18.0	6.0	6.0
Strong ale	20.0	8.0	9.0
Mild ale	14.0	5.0	4.5
Light bitter ale	12.0	5.0	4.5
Lager beer	14.0	6.0	4.0
Table-beer	6.0	2.0	2.0

As much has been written on beer-drinking, often without knowledge, it is worthy of note that experiments recently carried out in Berlin show that beer is not only a food of considerable value, but that it favours the assimilation of other foods partaken with it. These scientific investigations confirm the practical observations that beer, bread, and cheese make an appetising and nutritious whole.

Maladies (Defects) of Beer.—Beer is liable to many defects which render it unsaleable. These

defects are usually due to the growth of various micro-organisms for which beer, containing as it does carbohydrates and nitrogenous and mineral matter, forms a very suitable culture medium. The boiling and consequent sterilisation of the wort and the preservative power of the hop, aided by careful guarding from infection, usually enable beer to remain free from such attacks until consumed. This period, for the cheaper kinds of draught ale, extends only over a few weeks; for bottled ales, some months; and for export and strong ales, even years. In fact, special beers have been kept over fifty years in a sound condition. The diseases of beer were first investigated by Pasteur, who described many of the most important disease organisms. This work was of far-reaching importance, as it was the beginning of the study of micro-organisms, and led, among other results, to the study of those organisms which produce disease in man. Thus does humanity owe a great and lasting debt to brewing research. This work was followed up and developed by Hansen, who devised a method for producing the yeast required for pitching from a single selected cell, thus ensuring that the pitching yeast was not only free from disease organisms, but composed of the yeast giving the best flavour, &c., to the beer. This method of preparing pitching yeast is now in general use by lager-beer brewers, but, owing to difficulties not yet overcome, is not employed to any extent by ale and stout brewers. The defect that is first evident in beer is dullness or stubbornness in brightening. In the old days of pewter mugs this was not so important as to-day, when the use of glass is widespread. This defect may be due to a disease yeast which does not settle out easily, or to a bacterial growth, or to some finely divided wort constituent. Another common defect of beer is acidity. This is caused by bacteria producing acetic or other acid from some of the constituents of the beer; sometimes these bacteria are present in such quantity as to make the beer dull. If air obtains access to the beer, through the absence of a slow alcoholic fermentation or other cause leading to the loss of carbonic acid, mould-like organisms may grow in the beer, making it acid and thick. The beer may even be bright and sparkling and yet have an unpleasant taste and odour, and this may be due to the growth of disease yeasts. The study of the microbiology of beer has been developed greatly by recent observers, and the control of the fermentative changes which take place requires the services of a competent mycologist.

The shortage of cereals due to the war of 1914-18 resulted in severe restrictions on beer-brewing in the belligerent countries. In Great Britain the amount permitted was reduced in 1918 to one-third the normal quantity of standard barrels, and the average specific gravity of the worts was not to exceed 1030°. This resulted in the production of about 18 million barrels (one-half the normal brewing). In the same year in the United States of America the amount of materials permitted was reduced by 30 per cent., and the beer was not to exceed 2½ per cent. alcohol. Ultimately the total prohibition of the sale of alcoholic drink was enacted. The Central European powers had great difficulties in obtaining any brewing materials, and the average specific gravity of the worts in 1917 was only 1006°, the pre-war average being 1048°. Only 5 per cent. of the normal quantity of malt was allowed, and other materials, such as the roots of couch-grass, carrots, and beet, were used. French brewers used chestnut meal and soya-bean meal as barley substitutes. Notwithstanding the gradual disappearance of restrictions, pre-war conditions are not likely to return soon. In Great Britain the average specific gravity of the wort is restricted to 1044°, and in Ireland to 1051°;

but the bulk is unrestricted. The Central Powers will probably recover still more slowly, and in the United States prohibition still remains in force.

Statistics.—In 1913 about 500 million bushels of malt and 2 million cwt. of hops were employed in brewing 207 million barrels of beer. The following are the amounts brewed and the consumption per head in the chief beer-producing countries:

	Millions of Gallons Brewed.	Gallons per Head Consumed.

United States of America	1685	18·3

According to the official figures for the United Kingdom for the year ending September 30, 1914, there were 2536 brewers of less than 1000 barrels per annum, altogether brewing 719,398 barrels; and 1111 brewers of over 1000 barrels per annum, altogether brewing 36,965,431 barrels. The total amount of the materials used was 52,525,634 bushels of malt; 92,385 bushels of unmalted grain; 1,566,506 cwt. of rice, rice grits, flaked rice, maize grits, flaked maize, and other similar materials; 3,279,709 cwt. of sugar; 62,655,438 lb. of hops; 19,503 lb. of hop substitutes; and from these were produced 37,684,834 bulk barrels of beer, and £14,011,900 duty was paid.

Taxation.—British beer has been taxed from early times. It was not, however, until the struggle between Charles I. and the Parliament had set in that the excise can be said to have been established. The tax then levied was a beer-duty, a greater amount being charged on 'strong' than on 'small.' A duty was laid on hops at the same time, and in 1697 upon malt. For the next 130 years these three duties remained in existence. In 1830 the beer-duty was abolished, chiefly owing to the difficulties and faulty methods of collection, and the malt-tax proportionately increased. In 1862 the duty was taken off hops. In 1880 the various taxes on beer were all merged in a beer-duty of 6s. 3d. per barrel of wort of a specific gravity of 1057 before fermentation, stronger or weaker worts paying a proportionate duty. This has been increased from time to time.

Beer Acts. See LICENSING LAWS, INN.

Beer-money—one penny per day when on home-service, as a substitute for an issue of beer and spirits—was from 1800 made an addition to the daily pay of non-commissioned officers and soldiers until 1873, when, the stoppages for rations

having been abolished, the opportunity was taken to consolidate beer-money and pay proper.

Beer'sheba, now BIR-ES-SEB'A ('well of swearing,' or 'well of seven'), so called because of the covenant Abraham entered into here with Abimelech the Philistine king, which he ratified with an oath and a gift of seven ewe lambs. Beersheba was situated on the southern border of Palestine, about 52 miles SW. of Jerusalem, and formed the limit in that direction of the Israelitish dominion. In the 4th century A.D., it was the seat of a large village, with a Roman garrison; some of its churches were standing in the 14th century. A heap of ruins now marks the site of the village. Two of its wells are still almost always full of water. The shafts are of round masonry, worn with the water-drawers' ropes, and they have no parapet.

Beestings (technically *colostrum*) is the term applied to the first milk yielded after delivery. It differs not a little from ordinary milk, and generally appears as a turbid, yellowish, viscid fluid, similar to soap and water. When examined under the microscope, it is found to contain, in addition to the ordinary milk corpuscles (see MILK), peculiar conglomerations of very minute fat granules, which are hence known as colostrum corpuscles. The chief chemical differences between beestings and milk are, that the former is very deficient in casein and proportionately rich in albumen, and that it contains nearly three times more salts than the latter. It is probably this excess of salts that usually causes it to exert a purgative effect upon the new-born offspring, and thus to remove the Meconium (q.v.) which has accumulated in the fetal intestine.

Beeswax. See WAX.

Beeswing (so called from its appearance), a filmy crust of tartar formed in port and some other wines after long keeping. See WINE.

Beet (*Beta*), a genus of *Chenopodiaceæ* (q.v.). The species are not numerous; they are mostly biennials, with smooth, ovate, stalked root-leaves, and tall, leafy, flowering stems. They are natives of the temperate parts of the Old World. The Common Beet (*B. vulgaris*) is a native of the shores of the Mediterranean, but is now in very

Common Beet.

general cultivation both in fields and gardens, chiefly for the sake of its large succulent roots, which are used as food for man and cattle, and from which also sugar is extracted (see SUGAR). The variety known as Red Beet is the most esteemed for garden cultivation. Of this there are many sub-varieties, distinguished by the form of their roots, some being tap-rooted or carrot-like, others turnip-shaped, and by the depth of purple or crimson colour they all more or less exhibit. The darkest crimson coloured are the most highly esteemed, partly on account of their more pleasing appearance when cooked, but also because they contain a larger amount of mucilage and saccharine matter than the lighter tinted kinds. Roots of medium size are preferred to those that are larger. It forms a favourite pickle, is used in salads, and is also very agreeable as a boiled vegetable when properly dressed. It is more nutritive and whole-

some than any other cultivated 'root' except the potato. When deprived of the greater part of their juice by pressure, the roots may be used as a substitute for malt. They have also in times of scarcity been ground and mixed with flour for bread-making in continental countries. The seed is sown late in spring that the plants may not produce flowering stems the first year, which would render the root fibrous and useless.—Mangold-wurzel (q.v.), so valuable as a field-crop for food of cattle, is, in general, regarded as merely a larger and coarser variety of the common beet, in which the red colour is comparatively little exhibited.—The White Beet of our gardens (*B. cicla* of some botanists) is now also generally supposed to be a mere variety of the common beet, with little or no red in its roots or leaves, and a comparatively slender root. It is cultivated for the sake of its leaves, which are used in the same manner as spinach, and form an excellent substitute for it, especially in summer, when heat and drought deprive it of its essential succulence. The leaf-stalks and midribs of the leaves, especially of a variety in which these parts are unusually developed, are blanched and dressed for table in the same manner as sea-kale, and named *Chards*. Sea-beet (*B. maritima*) grows wild upon the shores of Britain, and differs from the common beet in its perennial root, its partly prostrate stems, and other characters. The leaves are used for food in Ireland, as are also those of *B. Bengalensis* in the East Indies.

The process of making beet-sugar will be treated at SUGAR. The development of this manufacture in France, Austria, and Germany enormously extended the cultivation of beet-root, and importation of beet-sugar seriously affected the sugar trade in Britain. The growth of the beet-sugar manufacture, fostered by bounties, was especially rapid in Germany and Austria. In France the growth was not so rapid, though manufacture and exportation were also stimulated by bounties. The abolition of sugar bounties (from 1st September 1903), agreed to by the Brussels Sugar Bounties Conference, 1902, very considerably affected the sugar trade and other trades dependent on it. Britain withdrew from the Convention in 1913. About 1883 the production of beet-sugar began to exceed that of cane, and this lead was maintained till 1910-11, when cane-sugar again took the lead with a production of 8,526,800 tons against 8,393,000 tons of beet-sugar. The area and conditions of cane-sugar countries thereafter increased the lead. In Germany nearly 11 per cent. of sugar is obtained from a given weight of beet-root. A large proportion (from $\frac{1}{2}$ to $\frac{3}{4}$) of the saccharine matter of the sugar-cane is not saccharose, but glucose, which is not available for sugar; whereas in beet there is little or no glucose at all, nearly the whole of the saccharine matter being saccharose. Beet-sugar, discovered by Markgraf, was manufactured about 1800 at Breslau, but the process was made a practical success by Chaptal and Delessert in 1811-12. The beet grows admirably in Britain and in Ireland; non-success in the manufacture is attributed rather to lack of method and organisation than to insufficiency of sunshine for ripening the saccharine element. The first modern factory in Britain was established in 1913. After extraction of sugar the dried slices are used as cattle-food. See J. W. Robertson Scott, *Sugar-beet* (1912).

Beet-fly (*Anthomyia betæ*), a dipterous insect which sometimes infests crops of beet or mangold-wurzel. In spring the very small eggs are laid in patches on the under surface of the leaves. The hatched maggots, which are about a third of an inch long, devour the soft parts, and after about a month of voracious life become pupæ, which are

usually buried in the ground. In about a fortnight the flies appear, measuring about half an inch from tip to tip of expanded wings. There seem to be two or more broods, and the last set of pupæ remain as such during the winter. It has not been noted as a frequent pest in Britain, but did great damage in 1880. Dressing with guano, soot, and especially superphosphate, was found efficacious. The genus includes a large number of forms. Compare CABBAGE-FLY, TURNIP-FLY; and Miss Ormeiod's *Injurious Insects*.

Beethoven, LUDWIG VAN, one of the greatest of musical composers, was born at Bonn, December 16, 1770. The family was originally Dutch, from near Louvain. The father was a tenor singer in the elector's band at Bonn, at £25 a year, a man of irregular life and severe temper. The mother appears to have been of no account. Ludwig's teachers were his father, Pfeiffer, and Van den Eeden and Neefe, both court-organists; also Ries for violin, and Zambona for letters. He was soundly and solidly taught, except in counterpoint, but was not precocious. Thus his first symphony dates from his 31st year, an age at which Mozart had written forty-five, including many of his greatest works. He joined the band, April 26, 1783, as accompanist, and on June 27, 1784, was made second organist. In 1787 he paid a short visit to Vienna and played to Mozart. About this time he began to be intimate with Count Waldstein and with the Breuning family, at Bonn. In 1788 the elector remodelled his band, and formed a national opera, at which the best works were performed. Beethoven played the viola in it, and Reicha, Ries, and Romberg were members. On November 20, 1789, the father's salary was transferred to Ludwig, and he became head of his family. In 1790 he wrote a cantata on the death of Joseph II. (not discovered till 1884). In the Christmas of that year he first saw Haydn. In 1791 we first hear of Beethoven's extempore playing, and he is already using the sketch-books so characteristic of him. In July 1792 Haydn again passed through Bonn, and warmly praised and encouraged him; and very shortly afterwards the elector sent him to Vienna to study under that great composer. He left Bonn in November, at the end of his twenty-second year. His compositions up to this date were unimportant; the cantata, two string Trios (ops. 3 and 8), two easy Sonatas (op. 49), the two piano Rondos (op. 51), are all that can be said to survive. But though thus backward, his character and his musical knowledge were fast maturing and consolidating. He displays the obstinacy, the humour, the absorption, the power of attachment of his later life; the best people of Bonn are devoted to him, and all believe strongly in his future. He is already one of the finest extempore players of the day.

In November 1792 he is established in Vienna, taking lessons in counterpoint from Haydn, and, during Haydn's absence in London, from Albrechtsberger; also from Schuppanzigh on the violin. He learned also from Salieri and E. A. Förster. In July 1795 he published the three Trios (op. 1); and on March 9, 1796, the three piano Sonatas (op. 2); the two piano Concertos in B flat and C were composed before April 1795; *Adelaide* was written that year; the Sonata in E flat (op. 7) was published October 1797; that in D (op. 10, No. 3), September 1798, &c.

Henceforward his works are composed in regular succession:

1800. Six String Quartets; C minor Concerto; Symphony No. 1; Septet; *Prometheus*; *Mount of Olives*.
1801. Quintet in C; Sonatas ops. 26, 27, 28

1802. Symphony No. 2; Sonatas, piano and violin, op. 30. His deafness becomes serious. Letter called 'Beethoven's Will,' dated October 6.
1803. *Kreutzer* Sonata; piano Sonatas, op. 31.
1804. *Eroica* Symphony; *Waldstein* and *Appassionata* Sonatas.
1805. *Fidelio* produced November 20 (Overture 'No. 2'); piano Concerto in G; three Quartets, op. 59. This year the French occupied Vienna.
1806. *Fidelio* (2d version, Overture 'No. 3'); Symphony No. 4; violin Concerto.
1807. Overtures *Coriolan* and *Leonora* 'No. 1'; Mass in C.
1808. Symphonies 5 and 6; piano Trios in D and E flat; Choral Fantasia. This year brought an offer from King Jerome Bonaparte to direct his music at Cassel, but it ended in a guarantee from the Archduke Rodolph and Princes Lobkowitz and Kinsky to pay him an annual income of 4000 paper florins—at that time worth £210.
1809 was the year of Aspern and Wagram, and the second French occupation of Vienna; but composition went on, and we find the piano Concerto and Quartet in E flat, the Sonatas in F sharp and E flat (op. 81a), and many small works. Haydn died May 31.
1810. *Egmont* music; the Quartet in F minor, besides some small military pieces.
1811 produced the piano Trio in B flat; the music to *King Stephen*, and the *Ruins of Athens*. The latter part of this summer he spent at Teplitz.
1812. Symphony No. 7, May 13; second visit to Teplitz, Carlsbad, and Franzensbrunn; meeting with Goethe; returns by Linz, where he completed the 8th Symphony, and two pieces for trombones, to Vienna: Sonata for piano and violin, op. 96, completed and played at Vienna before the close of the year.
1813. Battle of Vittoria, June 21; composition of the *Battle Symphony*, produced with Symphony 7 at a great concert, December 8. Summer spent at Baden.
1814. Symphony No. 8 produced February 27; *Fidelio* rewritten, and given May 23; Sonata, op. 90, August 16; Overture, op. 116, October 4; Congress at Vienna; Cantata, *Der glorreiche Augenblick*, November 29; *Tournament* music (unpublished), November 23. Lawsuits with Maelzel and with Count Kinsky's heirs—the beginning of troubles.
Up to this date, notwithstanding the drawbacks consequent on his deafness, which was now total, he seems on the whole to have enjoyed life. The next period was a far more painful struggle.
1815. Troubles still continue. Quarrel with Stephen Breuning. Death of his brother Carl, November 15. Compositions few; Sonatas, piano and cello, op. 102; *Meeresstille*; Sonata, op. 101; arrangement of Scotch songs.
1816. *Liederkreis* composed, April. Lawsuit with Carl's widow; appeals; terrible troubles. Lawsuit with Professor Lobkowitz; pension reduced to £110; Philharmonic Society buys Overtures *Ruins of Athens*, *King Stephen*, and op. 115, for £78, 15s. Last appearance in public, April 20.
1817. Nothing but worries and troubles. Beginning of *Choral Symphony*.
1818. Piano sent by Broadwood, February. Sonata, op. 106, and Mass in D both begun; 9th Symphony continued. Summer and autumn at Modling; anxieties about his nephew.
1819. At Modling; work and worries still continue.
1820. Appeal decided in his favour (January), and his nephew goes into his charge. Sonata, op. 109. Mass proceeding.
1821. Sonata, op. 110, December 25.
1822. Sonata, op. 111, January 13; Mass completed March 19; at Baden, Overture, op. 124; 9th Symphony proceeding. Reconciliation with Stephen Breuning.
1823. Symphony proceeding; 33 Variations, op. 120; Symphony finished at Baden, September 5. Visit of Weber and Benedict, October 5; Rossini-fever at its height, and neglect of all other music;

- proposal to write an opera, and worries thereon; subscriptions to Mass unsuccessful.
1824. Mass in D and 9th Symphony performed May 7. Quarrels with his best friends. Autumn at Baden. Quartet, op. 127, completed October. On returning, moves into Schwarzschanerhaus, where he died; illness in the winter.
1825. At Baden from May 2 to October 15. Quartets in A minor, op. 132, and B flat, op. 130, completed.
1826. C sharp minor Quartet, op. 131, written; young Carl banished Vienna for misdeeds; they visit Johann Beethoven at Gneixendorf; last Quartet, op. 135, composed October 30; present finale to B flat Quartet composed November; returns to Schwarzschanerhaus at Vienna, December 2; Beethoven takes to bed, which he never again leaves; receives £100 from Philharmonic Society, also Handel's works from Stumpff of London. Makes acquaintance with Schubert's music.
1827. He died March 26, at a quarter to six P.M., during a thunderstorm, and was buried on the 29th at the Währinger Friedhof, outside Vienna.

Beethoven's music has not yet become at all antiquated. *Fidelio* still fills the theatre to overflowing, and a performance of his Mass in D is still the great ambition of conductors. His symphonies are now more played than ever before, and form the staple of all orchestral concerts. The same is equally true of his quartets and trios. His sonatas are not only the test of the greatest executants; but they are the indispensable material by which thousands of humble piano students are taught; and yet no one ever wearies of them. The reason of this is partly the nature of the thoughts, apart from the extraordinary energy and the stern conciseness which animates and controls them, and which are synonymous with his name; they are always noble, simple, unpretentious, and yet containing a depth of meaning which is ever fresh; they are also free from affectation or passing triviality; they seem to reach down to the common basis of humanity—to that which lies at the bottom of every heart; and thus his melodies often have a surprisingly fresh and modern effect, as if made yesterday. At the same time they are not vulgar; they have the geniality and common-sense of Haydn's thoughts, but are of a loftier and wider cast. In his music, as in life, the serious and the humorous mix, and set off one another, as they do in the works of Shakespeare. He must not be thought of merely as a musician. He himself has told us that he always worked to a picture or a scene. His music was as truly the expression of the mental image and emotion as is the language of the greatest poet or dramatist; it was never an exercise in mere technicality. Even the complicated fugues of his latest sonatas are as full of meaning as the other and less scientific movements. In some cases the 'subjects' which form the texts of his music are abrupt and individual beyond all precedent, in others they are steeped in heavenly beauty and feeling, in both instances because they are the representatives of corresponding emotions; and in all cases the world, which began by scoffing or shrinking, has approved them. The contrasts and varieties in the instrumentation and setting of his thoughts are truly wonderful; it is as if he had his hearers constantly in his eye, and was always thinking how his thoughts could be presented in some new light, and how the attention could be best kept up until the end of his discourse. His last works, those composed during and after the period of trouble and distress, which reached from 1815 to 1820, have something of their own—something rarely if ever found in the earlier years, and unknown in his predecessors. They seem to breathe more than beauty, energy, or variety of sound, and in some mysterious way to mingle morals with music, and to lift us into a higher

region and a keener air than any other compositions. But this cannot be explained; and no one who has felt what is meant will ask for an explanation. Another point is the extraordinary variety of the music. Not only each work, but each movement is entirely different from all the others of the same name or class; and here again is a point of resemblance to Shakespeare.

This pre-eminence is not the result of any sudden impulse or impromptu effort; on the contrary, it was the effect of enormous care and labour. Fortunately, many of his sketch-books are preserved, and they enable us to see how insatiable he was in altering and rewriting his work till he got it into exactly the proper shape, and the oftener rewritten the more spontaneous does it become in the end. There is hardly a bar in his music of which it cannot be justly said that it has been written fifteen or sixteen times. His best themes often first appear in a mere commonplace form, but by repeated alterations they are brought to their present natural and eternal shape. And when he has found the proper vehicle for his thought, he is never weary of repeating it, until, as in the Pastoral Symphony, the music seems to consist of the continual reiteration of a few pregnant ideas. His music was the expression of his great mind, and no pains were too great that could make it more noble or truly refined, or could add to its beauty. And the same attention is shown in everything. No one before was so careful to mark the intended pace, or the changes of expression, or the minutest *nuances*, or to see that his publications were correctly printed.

Beethoven was no doubt an innovator; but he was so as every original thinker must be who wants means to express what no one before has thought; only that in his case the thoughts were far greater and the expression far more varied than elsewhere. His early works can often be hardly distinguished from Mozart, and it is only by degrees that the nature of the man shows itself. (The Sonatas op. 7 and op. 10, No. 3; the Coda of Finale to Symphony No. 2, are some of these early steps.) But his innovations were legitimate, never for their own sake. He worked on the old lines till he found that he needed to enlarge or modify them. Thus he enlarged the introduction and the coda; he introduced episodes in the 'working-out'; he changed the minuet into the scherzo; he multiplied the key-relations of the movements; he introduced the chorus into the finale of a symphony; he invented the 'cycle of songs'; he put variations on a new footing, which has been adopted and extended by his successors; he initiated the modern use of 'programme-music'; and everything that he did was more serious, more thoughtful, and therefore more permanent than any one else's. At the same time, it is pure music of the grandest, most touching, and beautiful sort. While adhering to the framework which seems essential for all art that is to appeal to the race and not to cliques of individuals, he shows that such framework need be no impediment to the most passionate, most personal, most universal ideas. Other men have followed the road which he opened, and have carried still further his extensions of form; but no one has done it with the same powers, or with such unabated freshness, or has met with such wide recognition by all hearers and all minds of whatever tendencies or constitution. We often hear of 'Beethoven's three styles.' It means that he began writing as his predecessors wrote; that by degrees his own genius asserted itself and made his music stronger, broader, more deeply coloured, more beautiful, than music had ever been before; and that lastly his deafness, his poverty, the troubles of life, the

approach of the end, brought a peculiar and unearthly sentiment into his thoughts.

He accepted the orchestra as he found it, for the trombones were nobly employed by Mozart, and the double bassoon formed a part of the orchestra at Bonn, and was also used by Haydn. But there is much of the highest interest in his employment of the various instruments. Every one is sooner or later immortalised—the drum in the 4th Symphony, and in the E flat Concerto; the horn in the *Eroica*, 7th and Choral Symphonies; the bassoon in the 8th Symphony; the trombones in the *Benedictus* of the Mass in D, and so on. The orchestra of the 2d Symphony is obviously founded on that of *Figaro*, but in the *Eroica* all that is changed.

He raised the *status* of musicians as much as he had enlarged the bounds of the art. Mozart and Haydn had been salaried lackeys, but Beethoven would be no man's servant, and by his mere independence, and some secret spell which counteracted all his discourtesy, compelled the highest classes of Vienna to treat him as an equal. No one before or since can show such a list of dedications of his works, and all were apparently purchased by regard and not by money.

His character was simplicity itself; falsehood was absolutely foreign to his nature, and he carried truth and sincerity into *brusquerie*, and often into shocking rudeness. The books are full of stories of this, which cannot be given here. And yet, so great was the influence of his personality, that those to whom he was rudest were fondest of him. Princes, cardinals, high-born beautiful ladies, women like Rahel, and men like Goethe, were devoted to him, and put up with every unpunctuality and every incivility. Varnhagen von Ense, after several weeks' intimate communication, 'found the man in him much stronger than the artist.' His simplicity sometimes became credulity, blinded him to real facts, and made him often unfair and harsh. This showed itself unjustifiably towards his relations, and towards many of his best and truest friends. Such conduct must have been greatly due to his deafness, his sensitive nature, and his absorption in his music, and he was always ready to confess his error; he was full of the deepest feeling, and there is something wonderfully touching in his devotion towards his nephew, one of the meanest, most graceless scamps on record; but on whom, partly because he was left to him, partly because of his craving for affection, he lavished all his tenderness. His nature and his deafness drove his goodness inwards, and we must look to his music, and to the mystical aspirations with which he salutes God in the sunrise, or the beauty of the woods, for the deeply religious feelings of his great heart.

Though a Catholic by birth, and dying in that faith, he had little formal religion. And yet a more deeply religious mind never existed. In every trial his thoughts flew upwards, and his note-books are full of the most passionate ejaculations. God was to him the most solemn and intimate reality, whom he saw and welcomed through all aspects of nature, and in every mood of joy and sorrow. Living in a profligate city, and in a time of the loosest morals, and himself singularly attractive to women, his name is not connected with a single *liaison* or scandal. 'It is one of my first principles,' says he, 'never to stand in any relations but those of friendship with another man's wife.' Again, 'O God! let me find the woman who is destined to be mine, and who shall strengthen me in virtue.' He wrote no second opera because he could get no libretto of the virtuous, elevating cast which he thought essential, and which alone he would consent to set.

Beethoven was 5 feet 5 inches high, very broadly

and firmly built; his head large, and the hair black, thick, and abundant. His eyes were dark in colour, very bright, and peculiar.

The standard life by the American A. W. Thayer (3 vols. 1866-87), published in German, was partly rewritten and continued by Deiters (1901-7), finished (vol. v. 1908) by Riemann, and again, from Thayer's material, edited by Krehbiel (New York, 3 vols. 1921). See also the article in *Grove's Dictionary of Music and Musicians* and *Beethoven and his Nine Symphonies* (1896) by Sir G. Grove, writer of the preceding article; Nohl, *Beethoven described by his Contemporaries*, and his *Life and Works of Beethoven* (trans. 1880 and 1881; Beethoven's *Letters* (trans. by Lady Wallace, 1866, and by Shedlock, 1926); books by Schindler (1860), Rudall (1889), Crowest (1899), Von Frimmel (1901), Shedlock (1903), E. Walker (1905), D. G. Mason (1905), D'Indy (trans. 1914), and Bekker (trans. 1926). In 1889 the birth-house at Bonn was made a Beethoven museum.

Beetle, the name of an order of insects technically known as Coleoptera (the Middle English *bitula* or *bitela* is apparently from an adj. *bitul* or *bitel*, 'biting'). There are indeed some insects popularly called 'beetles' which are not Coleoptera, and some Coleoptera which would hardly be termed 'beetles,' but for practical purposes the two words are synonymous. They have generally the usual four wings, but the front pair form hard and horny covers for those behind, which alone are used in flight. The feelers or antennæ have only a few joints; the jaws or mandibles are almost always biting organs like those of the Cockroach (q.v.), and the fourth pair of mouth appendages (second pair of maxillæ) are completely fused together (see the article INSECTS in Vol. VI. of this work, and the illustration, figure 1, there). Beetles have a complete metamorphosis; the larvæ are usually grub-like, with or without legs; the pupæ are usually soft, with freely exposed appendages, with or without cocoons. There are about 150,000 described species of beetles, showing great variety in detail, both of structure and habit. They are conveniently divided into sub-orders, such as the Lamellicornes (e.g. scarabæes), the Rhynchophores (e.g. weevils). Most beetles are decidedly strong, voracious insects, acting as 'universal scavengers,' preferring to remain concealed during the day, and only on occasions taking to flight. Their food varies greatly from hard wood to soft fruits, from the carcasses of animals to dung, and a few become parasites. They are found in water and on land, on plants and among stones, burrowing in the ground and drilling holes in wood, in fact in almost every variety of habitat. Fossil-beetles begin to appear in the carboniferous strata, and are often found imbedded in amber. Their practical importance in regard to vegetation, and their numerous interesting peculiarities of form and habit, will be discussed under special articles.

Colorado Beetle.		Wire-worm.

Beetling. In some rural districts of Scotland the peasantry, when they have not ready access to a mangle, beat clothes, newly washed and dried, with a wooden mallet on a flat stone, and the operation is called beetling. The same term is applied to a finishing process in the manufacture of linen, and also of some kinds of cotton goods. Just as in the hammering by hand, the object is to fill up and give a finish to the cloth by flattening its surface. It is done by the rising and falling of upright wooden stamps, placed close together in a row, with their square butts resting on a roller over which the cloth passes under them. The stamps

are worked by the rotation of a horizontal shaft, acting with tapets, like the cylinder of a barrel-organ.

Linen weft yarns, and especially such as are used for heavy sail-cloth, are also beetled by this machine to soften them. But finer weft yarns of this material are now, instead of being beetled, passed through what is called a *softening machine*, which consists of two pairs of grooved wooden rollers with the requisite driving gear.

Beet-root Sugar. See BEET and SUGAR.

Beets, NICOLAUS, Dutch poet and writer, was born at Haarlem, 13th September 1814, and studied theology at Leyden. After serving at Heemstede, near Haarlem, he was in 1854 appointed to the pastorate of Utrecht, and in 1874 to the chair of Theology there. His poetical works have been collected (4 vols. 1873-81). Through the earlier pieces runs a strong vein of misanthropic sentiment, due probably to Byron, some of whose works he translated into Dutch (2 vols. 1835-37). His prose writings include *Camera Obscura* (13th ed. 1880), a series of tales and sketches of life and scenery in 'Holland, published under the pseudonym of 'Hildebrand'; they display keen observation and are extremely droll—he was called 'the Dutch Dickens.' He published also a number of theological and critical works; and he died 12th March 1903.

Befana, a corruption of *Epiphania* (Epiphany), which name in Italy has become personified for children as a toy-bringing old woman called *la Befana*. She is a kind of female counterpart of the Wandering Jew and Santa Claus combined, and is employed as a kind of bugbear to frighten naughty children. According to the popular story, she was busy cleaning the house when the three wise men of the East passed by on their way to offer their treasures to the infant Saviour, and when called to the window to see them, she said she could do so when they returned. They went home by another way, and she has ever since been watching for their return. On Twelfth Night she brings good children toys and sweetmeats, but bad children only find their stockings full of ashes. It was also customary in Italy, on the evening before the Epiphany (5th January), to carry an effigy called the *befana* in procession through the streets amid great rejoicings, but this has fallen greatly into disuse.

Beffroi. See BREACHING TOWER.

Beg, now always BEY ('lord'), a Turkish title, rather vague in its import, and commonly given to superior military officers and distinguished foreigners. In rank it stands between *Effendi* and *Pasha* (q.v.). It is often assumed without any authority, and nearly every young Turkish dandy allows himself to be addressed by the title. 'Beglerbeg,' or, more correctly, *Beilerbegi* ('lord of lords'), is the title given to the governor of a province.

Begas, KARL, court-painter to the king of Prussia, was born near Aix-la-Chapelle in 1794. He painted a great many biblical subjects for churches, as well as several historical pictures and portraits. He died November 23, 1854. Of his four sons, two became known as painters, and two as sculptors.

Begg, JAMES, D.D., born in 1808 at New Monkland manse in Lanarkshire, was educated at Glasgow University, and was licensed as a preacher in 1829. Minister of Liberton from 1835 to 1843, he 'came out' at the Disruption, and thenceforward to his death (29th September 1883) held the neighbouring Free Church of Newington, Edinburgh.

A man of fine presence and vigorous intellect, he distinguished himself by his old-world orthodoxy, his humour and combativeness, and his efforts to improve the houses of the poor. See the Memoir by Professor T. Smith (2 vols. 1885-88).

Beggar. See MENDICANCY, VAGRANTS.

Beggar-my-neighbour, a game at cards played by two persons, between whom the pack is equally divided. Holding their cards back-upwards, the players lay down a card alternately, till an honour is turned up, which is paid for by the adversary—four cards for an ace, three for a king, two for a queen, and one for a knave. Such payment being made, the winner lifts the trick; but if an honour is laid down during the payment, then the opposite party must pay for that in the same way; and so on, till a payment is made without an honour. The object is to win all the cards in the pack. The game is as old at least as 1777.

Beghards. Societies of laymen under this name first appeared in Germany, the Netherlands, and the south of France in the beginning of the 13th century, and were known in Italy as *Bizachi* and *Bocasoti*; but they never obtained the reputation enjoyed by the Beguine sisterhood. Towards the end of the 13th century they were commonly stigmatised as *bons garçons, boni pueri*, and such contemptuous titles, which expressed the low estimation in which they were held. On account of heretics of all sorts retreating into these half-spiritual communities, they were subjected to severe persecutions after 1367, and were gradually dispersed, or joined the orders of Dominicans and Franciscans. In the Netherlands, where they had preserved a better character than elsewhere, they maintained their ground longer, and were protected by Pope Innocent IV. (1245), in Brussels by Cardinal Hugo (1254), and in Liège by Pope Urban IV. (1261); but their communities disappeared in the 14th century. The most probable origin of our word *beggar*, according to Sir J. A. H. Murray, is none other than the old French *begart, begard*, or its synonym, *beguin*, whence the verb *beguigner, beguiner*, 'to act the beguin.' If this etymology be true, it serves to show how widely these lay mendicants must have been spread over Western Europe. See BEGUINES, and the article by Haupt in Hauck-Herzog there cited.

Begharmi. See BAGIRMI.

Beglerbeg. See BEG.

Begonia. This genus (which gives its name to a small order of doubtful affinities) contains a

Begonia rex.

large number of species which are cultivated in our greenhouses, partly on account of their usually

pink, unisexual flowers, and partly for their remarkable unequal-sided and often coloured leaves, to which they owe such various popular names as 'Elephant's ears' in the East Indies, or, more poetically, 'Angel's wings' in the Spanish Antilles and Mexico. They are almost all tropical plants; but a small species of *Begonia* ascends the Himalayas to at least 11,500 feet, often growing on the trunks of trees. The leaves and young stems are succulent and acid, and those of several species are used as pot-herbs or in tarts like rhubarb. The roots of some are used in their native countries as astrigents, and some of the Mexican species are used as drastic purgatives. According to Loudon, begonias were introduced into Great Britain from Jamaica in 1777, but they were little cultivated till 1840.

Beg-Shéhr, or KERELI GÖL, an extensive mountain lake in Asia Minor, 44 miles SW. of Konia, situated almost 3700 feet above the sea. It is over 30 miles long, and from 5 to 10 miles broad, and contains several islands. Its only visible outlet is a rivulet connecting it with the much smaller lake, Soghla Gol, the waters of which occasionally disappear altogether; and it is evident that a great part is carried off through subterranean channels in the limestone range of the Taurus. On its east and north shores are the towns of Begshehr and Kereli.

Beguines (BEGUINÆ, BEGUTTÆ), a sisterhood within the Catholic Church, first formed during the 12th century in the Netherlands. The origin of the word is doubtful. It is ascribed by some to a St Begga, who is said to have founded the first sisterhood in 696; by others to a priest named Lambertus le Bègues or le Bègue, who founded in Liège, about 1180, a society of pious women who were called by his name. The Beguines were not restricted by vows, nor did they follow the rules of any order, but were united under a superior for the exercise of piety and benevolence, and lived generally in separate small cottages, which, collectively, formed the *Beguinagium*. Their establishments were often enriched by liberal donations. A church, a hospital, and a house of reception or common entertainment, generally belonged to every community. The sisters were distinguished from the rest of the laity only by their diligence and devotedness, piety, modesty, and zeal for the purity of youthful education. Their most flourishing period was during the 12th and 13th centuries, when they spread themselves widely over France, Germany, and the Netherlands. As the pietists of the middle ages, they were often subjected to persecution by the mendicant orders of friars; but on account of their practical usefulness were long sheltered by the popes and councils as well as by the secular authorities. In the 13th and 14th centuries, through their sympathy with the persecuted Fraticelli (q.v.) and the 'Brethren and Sisters of the Free Spirit,' they were brought under the scrutiny of the Inquisition; and on account of certain immoralities, a synod held at Fritzlar in 1244 required that all candidates must be forty years old before they could enter a society of Beguines. These sisterhoods maintained their position in Germany and the Netherlands longer than in other countries. In Holland, they existed at the close of the 18th century. In Belgium there are beguinages at Antwerp, Bruges, and Mechlin, and two at Ghent. Of the latter, the larger forms a separate quarter of the town, with little brick-built cottages, convents and churches, arranged in streets and squares within a common wall, open to the visits of strangers. Living here a life of retirement and piety, the Beguines, in their simple dark dresses, go out as nurses to the hospitals, and per-

form other acts of kindness among the poor. Though they are under no monastic vow, it is their boast that none is known to have quitted the sisterhood. See BEGHARDS; also Haupt's article in the *Hauck-Heizog Realencyklopadie* (vol. iii. 1897), and Canon Hooynaert's *Ce que c'est qu'un Béguinage* (1922).

Begum (a feminine form corresponding to *Beg*, q.v.), an Indian title of honour equivalent to 'princess,' conferred on the mothers, sisters, or wives of native rulers. The Begum of Oudh (see HASTINGS, WARREN) is well known in Indian history.

Behaim, MARTIN, a famous cosmographer, was born at Nuremberg about 1459. He early entered into mercantile life, and in 1480 went to Portugal, where he soon acquired a reputation as a skilful maker of maps. In 1484 he accompanied the Portuguese navigator, Diego Cam, in a voyage of discovery along the west coast of Africa, and sailed as far as the mouth of the Zaire or Congo River. In 1486 Behaim sailed to Fayal, one of the Azores, but in 1490 he left Fayal and returned to Nuremberg. There he constructed a large globe, principally from the writings of Ptolemy, Pliny, Strabo, Marco Polo, and 'Sir John Mandeville.' It is still preserved by the family of Behaim in Nuremberg, and is a valuable record of the progress of discovery, though it exhibits little accuracy, even for that date. He was not nearly so great a traveller as he pretended, nor an expert cartographer; the beauty of his globe was mainly due to a friend, a miniature-painter called Glockenthon. Behaim again resided in Fayal from 1494 to 1506, and died at Lisbon in 1506. His two hemispheres represent all the knowledge Columbus had to go on. See Ravenstein's monograph on him (1909).—MICHAEL BEHAIM (1416-74) was a German *meistersänger*, a native of Sülzbach, and by profession a weaver.

Beham, two brothers, natives of Nuremberg, and both of them painters and engravers—Hans Sebald (1500-50) and Bartiel (1502-40). They are reckoned amongst Dürer's seven followers, the 'Little Masters,' and form the subject of a monograph by A. Rosenberg (Leip. 1875).

Behar and Orissa, or BIHAR AND ORISSA, a governor's province (under the Government of India Act, 1919), bounded by Nepal, Bengal, the Bay of Bengal, and the United and Central Provinces. It formed till 1912 part of the lieutenant-governorship of Bengal. It consists of the districts Patna, Tirhut, Bhagalpur, Chota Nagpur, and Orissa. Area, 83,181 sq. m.; pop. 34,000,000. In addition there are native states with an area of 28,000 sq. m. and a pop. of 4 millions. Hindus number 82 per cent. of the population, and Mohammedans 10 per cent. The Ganges flows through Behar, and the Mahanadi drains Orissa. Between Behar and Orissa the plateau of Chota Nagpur has an altitude of 2000 feet. The mean annual temperature ranges from 75° in Chota Nagpur to 82° at Cuttack in Orissa; the mean annual rainfall, varying from 50 inches in Behar to 58 inches in Orissa, is regular on the whole, and, except for rice cultivation, little artificial irrigation is required. Rice is the principal crop, Patna being the centre of the rice-growing areas. Other crops are wheat, barley, maize, oil-seeds, sugar-cane, indigo, tea, and tobacco. There are an agricultural research institute at Pusa, an agricultural college at Sabour, and several experimental farms in the province. About 60 per cent. of the coal output of India comes from Behar and Orissa. There are large iron-works at Singhbhum. Saltpetre is produced in considerable quantities. Other manufactures include articles of ebony inlaid with ivory and horn, silk and mixed silk and cotton fabrics, gold and filigree work, brass utensils, carpets, coarse cloths, &c. The capital is Patna

(q.v.). The other principal towns are Bhagalpur, Cuttack, and Daibhanga.

Behar, or **BAHAR**, a town of Behar, 54 miles SE. by S. of the town of Patna. The original city is nearly deserted, and the present town consists of houses scattered about its remains, and interspersed with fields, gardens, and groves. There are some remains of fine mosques. Behar has a considerable trade, chiefly in rice, European cloth, cotton, and tobacco; while silk, cotton cloths, and muslin are manufactured here. Pop. 48,000.

Behheading. See EXECUTION, GUILLOTINE.

Behemoth (Heb., plural of *b'hēmāh*, 'beast,' a word of Egyptian origin), the name of a large and strong four-footed beast, referred to once in the Old Testament Scriptures, Job, xl. 15-24. Gesenius proves that the description in the passage is more suitable to the hippopotamus than to any other animal, though the elephant has been suggested by some scholars.

Behistun, or **BISUTUN** (ancient *Baghistan*), the site of an ancient Persian city, 22 miles E. of the city of Kirmanshahan. It is noted for its famous precipitous rock, anciently known as Mount Bagistanus, which on one side rises perpendicularly to the height of 1700 feet. Diodorus relates that Semiramis encamped near the rock, and caused the lower part to be smoothed away and an inscription engraved on it in her honour. This, like many other traditions attached to the mythic queen, is now proved false. The rock bears inscriptions of Darius Hystaspes about 518 B.C. The inscriptions—which are in the three forms of cuneiform writing, Persian, Babylonian, and Median—set forth the hereditary right of Darius to the throne of Persia, tracing his genealogy, through eight generations, up to Achæmenes; they then enumerate the provinces of his empire, and recount his triumphs over the various rebels who rose against him during the first four years of his reign. The monarch himself is represented on the tablet with a bow in hand, and his foot upon

Rock Inscriptions at Behistun.

the prostrate figure of a man, while nine rebels, chained together by the neck, stand humbly before him; behind him are two of his own warriors, and above him, another figure (see cut). The Persian

inscriptions which Sir H. Rawlinson translated are contained in the five main columns numbered in cut 1, 2, 3, 4, 5. The first column contains 19 paragraphs and 96 lines. Each paragraph after the first, which commences, 'I am Darius the King,' begins with, 'Says Darius the King.' The second column has the same number of lines in 16 paragraphs; the third, 92 lines and 14 paragraphs; the fourth has also 92 lines and 18 paragraphs; and the fifth, which appears to be a supplementary column, 35 lines. The second, fourth, and fifth columns are much injured. Rawlinson fixed the date at 516-515 B.C.

See Rawlinson in *Journal of Royal Asiatic Society*, vol. x.; Jackson's *Persia Past and Present* (1907); and *The Sculptures and Inscriptions at Behistun*, by King and Campbell Thomson (who recopied them, 1907).

Behm, **DR ERNST**, a German geographer, was born January 4, 1830, at Gotha, where he died on the 15th of March 1884. In 1856 he became Dr Petermann's chief assistant in editing the famous geographical periodical, *Mitteilungen*, to the editorship of which he succeeded on his chief's death in 1878. In 1872 he commenced, in conjunction with H. Wagner, the useful *Bevölkerung der Erde* (vol. vii. 1882), intended as a statistical supplement to the *Mitteilungen*; and from 1876 he undertook the statistical department of the *Almanach de Gotha*. His more extended writings of this nature are full, accurate, and lucid.

Behmen. See BOEHME, JAKOB.

Behn, **APHRA**, the first English professional authoress, was born in 1640 at Wye, in Kent, the daughter of John Amis (not Johnson, a barber, as long believed), with whom as a child she sailed for Surinam. Her father, well connected, had the promise of a good post, but died on the voyage out. His wife and family settled in Surinam, and there Aphra met Oroonoko, 'the royal slave,' whose romantic story she was afterwards (1688) to combine with autobiographical matter in a novel which made her the first literary abolitionist and left its mark on Bernardin de Saint Pierre, Chateaubriand, Rousseau, and others. Returning to England about 1663, she married a merchant of Dutch extraction called Behn, but, already widowed by 1666, turned spy for a livelihood, and went to Antwerp, whence she sent naval and other information to the government. Left without funds and imprisoned for debt, 'Astrea,' as she called herself, abandoned the Secret Service when set at liberty, and quickly made her name in literature. Her first play, *The Forc'd Marriage*, was given late in 1670; of her score of dramatic works *The Rover* is perhaps best known. Her good looks, her conversation, won her friends—and enemies—among the greatest wits and highest society of the day. Her comedies, full of verve, enjoyed vast popularity, but later came to be a byword for licentiousness, and were neglected accordingly. She died 16th April 1689. Her works were edited by Montague Summers (6 vols. 1915).

Behring, or **BERING**, **VITUS**, a famous navigator, born in 1680, at Hørsens, in Denmark. He entered early the newly-formed navy of Peter the Great, and for the ability and daring he displayed in the wars with Sweden, was appointed to conduct an expedition of discovery in the Sea of Kamchatka. Sailing in 1728 from a port on the east of Kamchatka, he followed the coast northward until he believed, from the westward trending of the land, that he had reached the north-east point of Asia. After some years spent in explorations on the coasts of Kamchatka, Okhotsk, and the north of Siberia, he sailed in 1741 from Okhotsk towards the American continent, and sighting land about 58½° N. lat., he followed the coast northward for some distance: but sickness

and storms obliged him to return, and being wrecked on the desert island of Avatcha, since called Behring Island, he died there, December 19, 1741. Among the few who escaped, in a boat made from the wreck, was Steller, the naturalist, who has left an account of the voyage (St Petersburg, 1793).

Behring Strait separates Asia from America, and connects the Pacific with the Arctic Ocean. The proof that the two continents were not connected was given by a Cossack named Deschnev, who in 1648 sailed from a harbour in Siberia, in the Polar Ocean, into the Sea of Kamchatka. But his voyage was long regarded by Europeans as a fable, until Behring's (q.v.) expedition in 1728. The strait was explored and accurately described by Cook in 1778. The narrowest part is near 66° lat., between East Cape in Asia, and Cape Prince of Wales in America, where the capes approach within 36 miles; about midway are three uninhabited islands. The greatest depth is some 30 fathoms. Haze and fogs are the normal conditions of the atmosphere.—**BEHRING SEA**, a part of the North Pacific Ocean, commonly known as the Sea of Kamchatka, bounded W. by Kamchatka, E. by Alaska, S. by the Aleutian Islands, and N. by Behring Strait. There are several islands in this sea, and here also fogs prevail.—**BEHRING ISLAND**, the most westerly of the Aleutian Islands, barren and destitute of wood, but an important station of the Alaska fur industry. It has an area of 30 sq. m., and is noteworthy as the place where Behring, the discoverer, was wrecked and died in 1741.

Beilan, a pass in the northern extremity of Syria, on the east shore of the Gulf of Scanderoon, runs across the mountain-range of Amanus. It is the common route from Cilicia into Syria, and was used by Alexander the Great, and afterwards by the Crusaders. The town of Beilan (pop. 5000) lies near the summit-level of the pass, at an elevation of 1584 feet above the Mediterranean Sea.

Beira, a Portuguese province, bounded N. by Minho and Tras-os-Montes, S. by Estremadura and Alemtejo, E. by Spain, and W. by the Atlantic. Area, 9222 sq. m.; pop. 1,800,000. The surface is mountainous, and the soil on the plains sandy, and generally far from fertile. The mountain-slopes afford good pasturage for sheep and cattle, and from the hogs of Beira are made the well-known Lisbon hams. The products are corn, wine, honey, oil, flax, and various kinds of fruit. Sea-salt is obtained at the coast. The river Douro waters the whole of its northern, and the Tagus a portion of its southern boundary. Iron, coal, and marble are wrought in small quantity, and mineral springs are numerous. The province embraces the districts of Aveiro, Castello Branco, Coimbra, Guarda, and Vizeu. The capital is Coimbra.

Beira, a town and port (pop. 10,000) in Portuguese East Africa, near the mouth of the Pongwe (q.v.) River, whence run railways to Mashonaland and to the Zambezi (for Nyasaland). It drains the traffic of a vast interior and is rapidly developing.

Beiram. See BAIKRAM.

Beirut. See BEYROUT.

Beisan. See SCYTHOPOLIS.

Beit is an Arabic word, signifying 'house,' 'abode,' or 'place,' the Hebrew equivalent of which is *Beth*. In both languages it is employed in place-names; thus, in the former, we have *Beit-al-Haram*, 'the house of the sanctuary,' or 'the sacred house;' and in the latter, *Beth-el*, 'house of God;' *Beth-anj*, 'house of dates;' *Beth-abara*, 'house of the ford;' *Beth-lehem*, 'house of bread,' &c. See also BETHESDA, BETHSAIDA.

Beit-el-Fakih, a town of Yemen in Arabia, 50 miles S.E. of Hodeida (q.v.). Pop. 8000.

Beith, a small town of North Ayrshire, on the borders of Renfrewshire, 18 miles S.W. of Glasgow by rail. Its most notable manufacture is that of furniture in large cabinet-works. The chief building is the Speir School (1887), resembling the old college at Glasgow. Pop. 5000.

Beitullah (Arab., 'house of God'), the spacious building or temple at Mecca, which contains the Kaaba. See MECCA and KAABA.

Beja (the *Pax Julia* of the Romans), a town in the province of Alemtejo, Portugal, 101 miles S.E. of Lisbon by rail. It has a castle and a cathedral, and manufactures of leather and earthenwares. Among its interesting Roman antiquities, the chief are the south gate and an aqueduct. Pop. 10,000.

Bejan, or **BAJAN**, the name of the first or 'freshman' class in the Scottish universities of St Andrews and Aberdeen, and of old in many continental universities. The word is believed to be derived from the French *bec-jaune*, 'yellow beak,' a term used to designate a nestling or unfledged bird. The levying of *bejanaria*, or payments for 'first-footing' by students on entering college, was forbidden by the statutes of the university of Orleans in 1365, and of the university of Toulouse in 1401. The election of an *Abbas Bejan-orum*, or 'Abbot of the Greenhorns,' was prohibited by the statutes of the university of Paris in 1493. *Beanus* is another form.

Bejapur. See BIJAPUR.

Bejar, a town of Spain, 45 miles S. of Salamanca. It has cloth manufactures and an annual fair; and in the neighbourhood is a hot sulphur-spring. Pop. 10,000.

Bek, ANTONY, Bishop of Durham from 1283, took a prominent part in the Scottish wars of Edward I., and held a command at the battle of Falkirk. In 1300 he became involved in ecclesiastical disputes, which lasted till his death on 3d March 1311. He was a prelate of great magnificence and unbounded ambition, but chaste and liberal.—Another Antony Bek (1279-1343) was Bishop of Norwich from 1337; a Thomas Bek (died 1293) was Bishop of St David's from 1280; and a second Thomas Bek (1282-1347) was Bishop of Lincoln from 1342.

Bekaa. See COELE-SYRIA.

Beke, CHARLES TILSTONE, Abyssinian explorer and biblical critic, was born in London, October 10, 1800; received a commercial education; afterwards studied law in Lincoln's Inn, and devoted a great part of his attention to ancient history, philology, and ethnography. The results of these studies first appeared in his work, *Origines Biblicae*, or researches in primeval history (vol. i. 1834), which was an attempt to reconstruct history on the principles of the science of geology, and which gained him the Tubingen degree of doctor of philosophy. In 1837-38 he acted as British consul in Saxony. His historical and geographical studies of the East led Beke to consider the great importance of Abyssinia for intercourse with Central Africa. Supported only by private individuals, he joined in Abyssinia the party led by Major Harris, and distinguished himself (1840-43) by the exploration of countries lying to the south, previously almost unknown in Europe. He fixed the latitude of more than seventy stations, and mapped about 70,000 square miles of country. He also collected the vocabularies of many languages and dialects. The results of these researches appeared in *Abyssinia* (1845) and in various journals. Having returned to Europe, he excited the attention of geographers by his *Essay on the Nile and its Tributaries* (1847). In 1853 he had become partner in a Mauri-

tius mercantile house, and in 1856 he made unsuccessful attempts at establishing commercial relations in Abyssinia. In 1861 Dr and Mrs Beke journeyed in Palestine; and undertook in 1865 a fruitless mission to Abyssinia, to obtain the release of the captives. In 1870 he was granted a pension on the Civil List. At the commencement of 1874, Dr Beke started for the region at the head of the Red Sea, where he claimed (though his views are disputed) to have discovered Mount Sinai, east of the Gulf of Akabah, and not west as generally supposed. He died at Bromley, Kent, July 31, 1874, being engaged at the time on an account of his journey to Sinai, and a second volume of his *Origines Biblicæ*. Beke in 1852 edited, for the Hakluyt Society, De Veer's *Three Voyages towards China*; he also published *The Sources of the Nile* (1860); *British Captives in Abyssinia* (1865); *King Theodore* (1869); *Idol in Horeb* (1871); *Jesus the Messiah* (1872). His posthumous work, *Discoveries of Sinai in Arabia* (1878), was issued by his widow.

Békés, or BÉKÉSVAR, a town of Hungary, at the confluence of the Black and White Kiöcs, 113 miles SE. of Budapest. The inhabitants principally engage in agriculture, and trade in cattle, corn, and honey. Pop. 28,000. See also CSABA.

Bekker, IMMANUEL, a scholar distinguished by his recensions of the texts of Greek classics, was born at Berlin in 1785, studied in Halle, and in 1811 became professor of Philology in his native city, where he died 7th June 1871. The results of his researches in the libraries of France, Italy, England, and Germany, appear in his numerous recensions of texts derived solely from MSS., and independently of printed editions. The writers included in these recensions are Plato, the Attic orators, Aristotle, Thucydides, Theognis, Aristophanes, as well as Livy and Tacitus.

Bekker, BALTHASAR (1634-98), pastor at Amsterdam, wrote against the belief in Witchcraft (q.v.)

Bektashi. See DERVISH.

Bel and the Dragon, an apocryphal book of the Old Testament, originally appended to the Book of Daniel. It first appears in the Septuagint, and does not seem to have been accepted as inspired by the Jewish Church, nor is there any proof that a Hebrew or Chaldee version of the story ever existed. Jerome considered it a 'fable,' an opinion in which most modern readers will coincide. It was, however, one of the books declared canonical by the Council of Trent (1546). The aim of the writer appears to have been to warn against the sin of idolatry some of his brethren who had embraced Egyptian superstitions. See APOCRYPHA.

Belbeis (ancient *Bubastis Agria*), a town situated on the east arm of the Nile, Lower Egypt, 30 miles NNE. of Cairo; pop. 12,000.

Belcher, SIR EDWARD, admiral, born in 1799, entered the navy in 1812, and in 1816 took part in the bombardment of Algiers. In 1825 he was appointed assistant-surveyor to the expedition about to explore Behring Strait under Captain Beechey; and from 1836 to 1842 he commanded the *Sulphur*, commissioned to explore the western coast of America. Knighted in 1843, and for five years employed on surveying service in the East Indies, he was in 1852 appointed to the command of the unfortunate expedition sent out by government to search for Sir John Franklin. Belcher published *Narrative of a Voyage round the World in the Sulphur* (1843); *Narrative of a Voyage to the East Indies* (1848); *The Last of the Arctic Voyages* (1855), &c. In 1861 he became rear-

admiral of the Red, in 1866 vice-admiral, in 1867 K.C.B., and rear-admiral in 1872. He died 18th March 1877.

Belchitê, a town of Spain, on the Aguas, 22 miles SSE. of Saragossa. Here, on June 18, 1809, the French, under Suchet, completely routed the Spanish under General Blake.

Belem'. See LISBON.

Belem', or PARÁ, capital of the Brazilian province of Pará (q.v.).

Belemnites (Gr. *belemmon*, 'a dart' or 'arrow'), an interesting genus of fossil cephalopodous Mollusca, the type of a family called Belemnitidæ, to the whole of which the name Belemnites is very generally extended, and which is closely allied to the Sepiadæ, or Cuttle (q.v.) family. No recent species of Belemnites is known: fossil species are very numerous, and are found in all the jurassic and cretaceous strata, from the lowest lias to the upper chalk, some of which are filled with myriads of their remains. These remains are generally those of the shell alone, which is now known to have been an internal shell, entirely included within the body of the animal, like that of the cuttle. The

Belemnites pistiliformis.

shell, as seen in the most perfect specimens, is double, consisting of a conical chambered portion (the *phragmacone*), inserted into a longer, solid, somewhat conical or tapering, and pointed sheath, which is termed the *rostrum* or *guard*. The space between the phragmacone and sheath is occupied either with radiating fibres or conical layers. The chambers of the shell are connected by a tube (*strophuncle*), so that the animal probably had the power of ascending and descending rapidly in the water. From some well-preserved specimens we learn that its body was furnished with lateral fins, and that it had eight arms and two longer tentacles. The suckers seem to have been provided with horny hooks; and these it probably fixed upon a fish, and descended with its prey to the bottom, like the hooked Calamary (q.v.) of the present seas. Horny mandibles and remains of an ink-bag, like that of the cuttle, have been found in the last and largest chambers of the belemnites; but remains of this chamber, which must have contained all the viscera of the animal, are very rarely preserved, the shell having been very thin at this part. The part most commonly found, and generally known by the name of belemnite, is the solid *guard*, or point into which the sheath was prolonged behind the chambered shell. These have received such popular names as Arrowheads, Petrified Fingers, Spectre-candles, Picks, Thunderstones, &c., from their form, or from the notions entertained of their nature and origin. Belemnites appear to have been of very different sizes; some of the largest, with arms outstretched, must have been several feet in length.

Belfast, the largest and most prosperous town in Ireland, is a great commercial and manufacturing centre; it is since 1898 a county of a city, and since 1899 a county borough, once mainly in the county of Antrim, of which from 1850 it was the county town. It is 12 miles from the Irish Sea, 101 N. of Dublin, 130 SW. of Glasgow, and 156 NW. of Liverpool. The older portion of the town stands on an alluvial deposit not more than 6 feet above the sea-level. The river Lagan is crossed by the Queen's Bridge, by the Albert Bridge, by a railway bridge, by a bridge at Ormean, and by

the King's Bridge in ferro-concrete, more recently constructed. Belfast has a much more pleasant appearance than most British manufacturing towns. A fine street called Royal Avenue, driven in 1884 through the centre of the town from York Street to Donegall Place, contains the Post-office, the Ulster Reform Club, the offices of the Water Commissioners, the Public Library, and the Art Gallery and Museum. The Public Library has a number of branches. The Museum contains two unique collections—one of Irish antiquities, and the other the Horner collection of spindles and spinning-wheels. The Queen's University of Belfast has developed out of Queen's College, which in 1850, in affiliation with similar colleges at Cork and Galway, was incorporated as a university. In 1879 its constitution was dissolved, and the Royal University of Ireland was instituted in Dublin. During the next thirty years Queen's continued its career as a college, and in 1909 was constituted the Queen's University of Belfast. In 1881 the Presbyterian College had, in conjunction with the Magee College of Londonderry, the power conferred on it of granting theological degrees. Catholics and Methodists have colleges of their own. The Royal Academical Institution (whose centenary was celebrated in 1910) is a public high school. The Campbell College, opened in 1894, with its thoroughly equipped laboratories and workshops, furnishes a superior liberal education. The great Municipal Technical College, which began work in 1901, had twice between 1904 and 1910 to extend its five-storied building. Among its developments has been a co-ordination scheme of university education and technical education, whereby students can obtain their arts and science degrees.

Belfast is a prosperous town, the most progressive in Ireland. In 1821 the population was 37,117; in 1851 it was just over 100,000; in 1881, 208,122; in 1901 (with enlarged boundaries), 349,180; and in 1911, 386,947, of whom 75 per cent. were Protestants. In 1892 the chief magistrate had the title of Lord Mayor conferred on him, and Belfast was detached from Antrim and Down and made a county borough in 1899. The new City Hall, opened in 1906, claims to be the finest city hall in the United Kingdom; a quadrangle of classic design, it is surmounted by a dome 175 feet high, and cost over £300,000. In it were held the first meetings of the Northern Irish Parliament in 1921. In 1887 the Belfast Main Drainage Act was passed for the purpose of extending, at an expenditure of £300,000, the main trunk and intercepting sewers for collecting all the sewage and discharging it into the sea at a great distance from the town. Work was begun in 1923 on a new storage reservoir for the city; it is situated 40 miles south in the Silent Valley (Mourne Mountains). The gasworks, purchased by the corporation in 1874, and extended, have yielded a profit used in relieving local rates. Electric lighting was first installed in 1895 by the corporation. In 1905 the corporation acquired the whole of the street tramways for £364,448, and at once proceeded to electrify and extend the system from that of horse-traction. The Harbour Commissioners had already expended £500,000, when, under an act of 1883 and subsequent acts, they obtained power authorising an expenditure of over two and a half millions of money, and the entrance channel to the harbour is now deepened to 32 feet below high-water level of ordinary spring-tides. One of the graving-docks, opened in 1911, is among the largest and most convenient in the world, and is 886½ feet long by 100 feet wide on the floor. The quays extend a mile on each side of the river from Queen's Bridge. Belfast is the centre of the Irish linen manufacture, with a large number of spinning-mills and power-loom weaving factories, which, with

the warerooms, lapping-rooms, &c., are the chief source of employment in the city. Shipbuilding and marine engineering is one of the most flourishing industries, the two principal firms being Harland and Wolff and Workman, Clark, & Co.; the number of hands at Harland & Wolff's alone exceeds 20,000. Many of the finest vessels afloat have been built by Harland & Wolff, notably the White Star Line's *Oceanic* (17,274 tons), *Celtic* (20,904 tons), *Cedric* (21,035 tons), *Baltic* (23,876 tons), *Adriatic* (24,541 tons), and *Olympic* and the ill-fated *Titanic* (each 45,000 tons), these two being when launched the largest vessels in the world. Other industries are distilling, pork-curing, flour-milling; the manufacture of aerated waters, felt, artificial manures, ropes and cordage, machines, tobacco; and letter-press and lithographic printing. The chief exports are pigs, iron ore, linen, sheep, whisky, and potatoes. Here opposition to Home Rule has always centred. At intervals, as in August 1907, there have been serious riots between the lowest classes of the Protestant and Catholic population, which in and after 1920 developed into a continued terror. The city till 1918 sent four members to the House of Commons; its representation was then increased to nine, and a member was given to the university. In the parliament of Northern Ireland Belfast city has sixteen members and the university four. The Lord Mayor is *ex officio* a member of the senate. Stomont Castle, to the east of Belfast, was bought in 1921 to house the Northern parliament, ministries, and courts of justice. Lord Kelvin was a native, as were his brother James Thomson, Thomas Andrews, Sir J. Emeson Tennant, Sir Samuel Ferguson, and Sir John Lavery.

See Benn, *History of Belfast to the End of the 18th Century* (1877); Young, *Historical Notices of Old Belfast* (1896); D. J. Owen, *History of Belfast* (1921); and *The Corporation Year Book*.

Belfast, a city and port of entry in Maine, U.S., on the west side of Penobscot Bay, with shipbuilding and some manufactures; pop. 5000.

Belfort, a town of France, capital of the remnant left in 1871 of the department of Haut-Rhin, 117 miles ENE. of Dijon by rail. This remnant (235 sq. m.) took from the town its name, *Territoire de Belfort*, and consisted of those portions of Haut-Rhin which, seized by the Germans during the war of 1870-71, were restored to France by the preliminaries of peace arranged at Versailles, 26th February 1871. The strategical importance of Belfort was recognised by France on its cession by Austria in 1648, and it was fortified by Vauban. At the outbreak of the Franco-German war Belfort was a fortress of the first rank; and it maintained, from 3d November 1870 till 16th February 1871, a gallant defence against the Germans. It then capitulated, the defenders marching out with all the honours of war. A memorial of its defence was unveiled in 1884; and the fortifications were thereafter enormously strengthened. Pop. (1872) 8014; (1921) 39,301; of territory (1901) 91,763; (1921) 94,338.

Belfry (old Fr. *berfrei*; modern Fr. *beffroi*, of Teutonic origin, probably from O.H.G. *bergen*, 'to protect,' and *fridu*, 'peace,' hence 'shelter,' and so meaning primarily 'a place of safety'). Originally a kind of movable tower used for attack or defence in sieges, it came to mean a tower to protect watchmen, a watch-tower, beacon-tower, or alarm bell-tower, then any tower where a bell is hung—a bell-tower or turret. The change of *r* to *l* (as in *palfrey*, *pilgrim*, from Lat. *parafredus*, *peregrinus*) probably helped in the change of meaning, through association with *bell*. The belfry usually forms part of a church, but is sometimes detached from it—as at Evesham, Berkeley, and Beccles, in England, and

still more frequently in Italy (see CAMPANILE) Where a church was built in a deep glen, the belfry was occasionally perched on a neighbouring height, as at St Feve and elsewhere in Cornwall, and at Airdlach and Auldbar in Scotland At this last place the bell was hung upon a tree, as was common enough in Scotland at the close of the 17th century Where the belfry consists of a mere

Belfry at Bruges

turret, it is often called a *bell gable* or *bell cote* and is placed on the west end of the church, a smaller one being usually placed at the east end for the sanctus bell, for which reason it is placed over the altar Municipal belfries are more common on the Continent than in this country When the boroughs began to rise into importance after the 12th century, they asserted their right to have bells to call the burghers together for council or for action Thus detached belfries arose in the heart of towns, and were regarded as important symbols of their freedom At a later date, they often became part of the *maison de ville*, or town house, as at Glasgow and Aberdeen, in this country, at St Quentin and Douai, in France, and at Brussels, in Belgium The belfry attached to the building known as *Les Halles* (not the town hall) in Bruges was commenced in 1291 It is 353 feet high, and possesses a carillon of 48 bells, regarded as the finest in Europe It is well known through Long fellow's poem

Belgæ, the name given by Cæsar to the warlike tribes which in his time occupied that one of the great divisions of Gallia bounded on the N by the Rhine, on the W. by the ocean, on the S by the Sequana (Seine) and Matona (Marne), and on the E by the territory of the Irevni Their country was level, containing no mountains of any height, except the Vosges in the south. The name seems to have originally designated several powerful tribes inhabiting the basin of the Seine, and to have been afterwards used by Cæsar as a general appellation for all the peoples north of that river Most probably they were chiefly of Celtic origin, but within their territories were to be found both pure and mixed Germans

When South Britain was invaded by Cæsar, he found that Belgæ from the opposite shores of Gaul

had preceded him, and were settled in Kent and Sussex, having driven the aborigines into the interior The Belgæ in Britain resisted for nearly a century the Roman power, but were finally forced to yield to it Cæsar regarded them as German, but they rather seem to have belonged to the Celtic portion of the Gallic Belgæ Certainly none of the names of their three towns are Germanic See Rhys's *Celtic Britain* (1882), and Elton's *Origins of English History* (1882)

Belgard, a town of Prussia, in the province of Pomerania, on the Persante, 16 miles SSW of Koslin It has an old castle, and important cattle and horse markets There are also an iron foundry, sawmill, &c Pop 10,000

Belgaum, or BELGAM, the chief city of a district of the same name in the presidency of Bombay, situated to the E of the dividing ridge of the West Ghats, at a height of about 2500 feet above the sea, 55 miles NE of Goa Belgaum possesses a fort, which in 1818 was taken from the Peishwa by the British, under whom it has increased in wealth and size The native town lies between the fort on the east and the military cantonment The site of the town is well wooded, bamboos, mangoes, tamarinds, and banyans being plentiful It has a superior institution for the education of native youths The chief articles of commerce are dry fish, salt, dates, coconuts, con Cotton cloth is manufactured here Belgaum is a seat of the London Missionary Society Pop 30,000

Belgiojoso, a town of Lombardy, North Italy, in a fruitful plain between the Po and the Olona, 9 miles E of Pavia Pop 4000 —The Princess Cristina of Belgiojoso, an Italian authoress and patriot, was the daughter of the Marchese Trivulzio, and was born at Milan, 28th June 1808 In 1824 she married (unhappily) the Prince of Belgiojoso She was an enthusiastic labourer in the cause of Italian liberty, raised and supported a body of troops in 1849, travelled in the East, and lived many years at Paris A visionary and a poseuse, she was the protectress of Heine and the friend of Thiers, George Sand, Hugo, Dumas, and Gautier She wrote on Asia Minor and things Turkish, on Italian politics, and on the house of Savoy, as well as *Souvenirs d'Emile*, and died 5th June 1871 See *A Revolutionary Princess*, by H R Whitehouse (1906)

Belgium (Fr *Belgique*), one of the smaller European states, consists of the southern portion of the former kingdom of the Netherlands (as created by the Congress of Vienna), lying between France and Holland (i.e. the present kingdom of the Netherlands), the North Sea and Rhemish Prussia Its greatest length from north west to south east is 173 miles, and its greatest breadth from north to south, 105 miles

Area and Population —The whole area of Belgium is 11,373 sq m, or slightly over a third of that of Ireland The population at the census of 1880 was 5,520,009, and at that of 1910, 7,423,784 Beneath are given the provinces, their areas, their population at December 31, 1910, and their chief towns

Provinces	Sq Miles	Pop	Chief Cities
Antwerp	1 093	968 677	Antwerp
West Flanders	1 249	874 185	Bruges
East Flanders	1 158	1 120 835	Ghent
Hainault	1 437	1 282 867	Mons
Liege	1 117	885 841	Liege
Brabant	1 268	1,469 677	Brussels
Limburg	981	275 691	Herzelt
Luxemburg	1 706	231 215	Arlon
Namur	1 414	362 846	Namur

Total 11 873 7 423 784

At the same date the kingdom contained twenty three towns with over 25,000 inhabitants Of these the largest were Brussels, the capital, 665,806

(including suburbs); Antwerp, 320,640; Liège (or Liége), 174,768; and Ghent, 165,149. The treaty of Versailles added in 1919-20 the German districts of Moresnet, Malmédy, and Eupen, as well as the neutral territory of Moresnet, with an area of 370 sq. m. altogether, and a population estimated in 1920 at 64,500. These additions bring the total population (estimated 1920) to 7,684,272.

The population of Belgium is partly Nordic (blond, long-headed) and partly Alpine (darker, round-headed). The division in physical characters answers generally to the division in language between the Teutonic Flemings (see HOLLAND for language and literature) and the Latin Walloons (q.v.). East and West Flanders, Antwerp, and Limburg are almost wholly Flemish; and Brabant mainly so. The line between the Flemish and Walloon districts runs east and west, a little south of Brussels (which is a French enclave), and is sharply defined, the Flemish part being the richest and most cultivated. The French language has gained the ascendancy in educated society and in commercial life; but Flemish prevails numerically in the proportion of eight to seven. Both are in official use. There is a considerable German-speaking population. See the paragraphs on *Culture* and *Literature* below.

Belgium is the most densely peopled country in Europe, the population being estimated in 1920 at 670 to the sq. m., as compared with 544 in the Netherlands and 649 in England and Wales (1921). In Brabant the density was 1237 per sq. m., in East Flanders 1056. The increase of the population is due largely to the steady excess of births over deaths, which from 1881 to 1885 averaged 57,800 annually, and in 1901 was actually as much as 84,000. This may be compared with the returns from France during the same period, where, with an area seventeen times greater, and a population more than six times as large, the total average excess was only 93,300. In 1910, 3,220,662 spoke Flemish only, 2,333,334 French only (including Walloon), 31,415 German only, 871,288 Flemish and French, 74,993 French and German, 8652 Flemish and German, and 52,547 spoke all three languages. There were, besides, 248,562 foreigners, mainly Dutch, French, and German.

Physical Aspect.—Belgium is, on the whole, a level and even low-lying country, diversified, however, by hilly districts. In the south-east a western branch of the Ardennes highlands separates the basin of the Maas from that of the Moselle, but attains only the moderate elevation of 2000 feet. In the northern portions of Antwerp and Limburg, a naturally unfertile district named the Campine, composed of marshes and barren heaths and irrigated lands, extends along the Dutch frontier. In Flanders the land becomes so low that, in parts where the natural protection afforded by the dunes is deficient, dikes have been raised to check the encroachments of the sea; and the once impassable morasses of the *Morini* and the *Menapii*, which stayed the progress of Cæsar's legions, are now drained and converted into fertile fields surrounded by dense plantations. Colonies having been settled on whatever patches of the sandy, marshy Campine it was deemed possible to reclaim, it has been largely cleared and drained, and become a thriving agricultural and coal-mining district. The coast is said to be undergoing a change by which the land southward is gradually gaining on the sea, while the northern coast is losing.

Hydrography, Climate, Agriculture, &c.—The abundant water-system of Belgium is chiefly supplied by the great navigable rivers Scheldt and Maas, both of which rise in France, and have their embouchures in Holland. The Scheldt, like

the Maas, is navigable all through Belgium. Its tributaries are the Lys, Dender, Durme, and Ruppel. The Maas, or Meuse, receives in its course the waters of the Sambre, the Ourthe, and the Roer. These natural hydrographical advantages are increased by a system of canals. The climate is, in the plains near the sea, cool, humid, and somewhat unhealthy; but in the higher south-east districts hot summers alternate with very cold winters. The mean annual temperature at Brussels is 50° F. The rainfall ranges from 27.5 inches in the west, to 40 inches in the district east of the Maas. The Ardennes districts yield a large supply of wood, and their forests abound in game and other wild animals; while the level provinces raise all kinds of grain—wheat, rye, oats, and barley—potatoes, leguminous plants, hemp, flax, colza, tobacco, hops, dye-plants, and chicory. The beet is cultivated both for sugar and for fodder. About two-thirds of Belgium is in ordinary cultivation, more than one-eighth is meadow and pasture, one-sixth is under wood, and less than 600,000 acres are waste or water. Some hundreds of acres are devoted to vineyards, but the wine produced is of an inferior quality. Good pasturage is found on the slopes and in the valleys of the hilly districts, and in the rich meadows of the low provinces. Gardening occupies a great area; indeed, it has been said that the agriculture of Belgium is gardening on a large scale, so carefully and laboriously is every inch of soil cultivated by the farmers, the vast majority of whom are small holders owning less than one hectare (about 2½ acres) of land. The spade is still the principal instrument used. The interests of agriculture are promoted and superintended by official provincial commissioners, whose delegates, with specialists, form a supreme council. The state supports agricultural schools and experimental stations, and at many middle-class state schools courses of agricultural lectures are delivered to the farmers of the district. Belgium is famous for its horses. In the Campine the care of bees and the cultivation of the silkworm are encouraged, and its butter is considered the best in Belgium. There are valuable fisheries on the coast.

Geology.—The geological formations of Belgium are closely associated with those of France and Britain. The greater portion of the country is covered with Tertiary deposits. A line drawn across the course of the Scheldt, by Mechlin, along the Demer and Maas, will have on its northern and north-western aspect a tract of Tertiary deposits, bounded northwards by the sea. In these Tertiary strata the different geological periods are fully represented; but only the Pliocene is rich in fossils. The Secondary deposits occupy an extensive tract in the centre of Belgium, between the Scheldt and the Demer. The most important district, economically, is the south-western, consisting of Palæozoic rocks—Cambrian, Ordovician, Silurian, Devonian, and Carboniferous.

Mineral Products.—Belgium is rich in minerals, which, next to its abundant agriculture, constitute the chief source of its national prosperity. The four provinces in which they are found are Hainault, Namur, Liège, and Luxemburg. These yield lead, copper, zinc (calamine), manganese, alum, peat, marble, limestone, granite, slate, iron, and coal. Lead is wrought to some extent in Liège, copper in Hainault and Liège, manganese in Liège and Namur, black marble at Dinant, slate at Herbeumont, and zinc principally in Liège. But these products are insignificant compared to the superabundance of coal—from anthracite to the richest gas coal—and iron, in which Belgium ranks next to England. Nevertheless large quantities of iron and steel have to be imported to supplement native production. The mines are

superintended, under the minister of industry and labour, by a corps of mining engineers. The coal-mines of Belgium employ some 160,000 persons (110,000 underground).

Manufactures.—The chief manufactures are linen, woollens, cotton, silk, lace, leather, and metals. Flax is one of the most valuable products of Belgium. The great seats of the linen manufacture, the oldest in Belgium, are in Flanders. The lace industry has fallen off in importance, but still employs many thousands of workers. Lace-makers sitting at work at their house doors are a familiar sight in the Flemish towns. Centies of the woollen manufacture are Ghent, Tournai, and especially Verviers. Brussels and Louvain have large carpet manufactures, and Hainault supplies a considerable amount of hosiery. The principal seat of the cotton trade is Ghent, where the industry was first established in 1798. Belgian leather has a good reputation, and the manufacture of gloves has made great progress. Metallurgy also has rapidly increased in productiveness since 1816, when Cockerill (see *SERAING*) introduced into Belgium the English method of smelting iron with coke. The principal seats of the metal manufacture are Liège, Ghent, Charleroi, Mons, and their neighbourhoods. There are large ordnance-foundries at Liège and Antwerp, and celebrated makers of firearms and machinery in Liège; nail-making at Charleroi; manufactures of copper at Malines, and of tinware at Liège; wire and brass factories at Namur, Liège, and Brussels; zinc manufactures at Liège; and lead and shot factories at Ghent. Gold and silver goods are manufactured at Brussels, Liège, and Antwerp. Diamonds are cut at Antwerp. Besides these, we may mention the straw-bonnet manufacture in the neighbourhood of Liège; the calico-printing at Ghent and Brussels; the paper fabrics of Brussels and Liège; the great glass-works of Charleroi, Liège, and Namur; the porcelain of Tournai; and the sugar-refineries, motor-car works, paper-mills, artificial-silk works, breweries, mostly small, and distilleries.

Commerce.—In the middle of the 13th century Flanders, with Bruges as its chief seat of manufactures, had surpassed all its neighbours in industry. After the discovery of America, Antwerp took the place of Bruges. But the unhappy period of Spanish oppression and the war in the Netherlands deeply depressed Flemish commerce. Separation from Holland has been indirectly favourable to the development of Belgian resources; and an admirable network of railways, including light railways, or 'chemins-de-fer vicinaux,' has greatly promoted commerce. There are over 1200 miles of navigable rivers and canals.

The unit of the Belgian monetary system is the franc, and in 1865 Belgium, along with France, Italy, Switzerland, and Greece, entered on a monetary league, in which these states agreed to adopt the French decimal system of coins, weights, and measures, and established a reciprocity of currency, whereby their respective unit coins would have the same value throughout their territories.

Among the principal articles of export are coal, flax, linen, woollen and cotton goods, glass, chemicals, machinery, sugar, hides, firearms, and nails. About a third of the whole is consigned to France, and most of the remainder to Germany, England, and Holland. The carrying trade is almost entirely in the hands of the British, the native shipping being only some 200 vessels, of under 340,000 tons burden, not including fishing-vessels. In 1919-21 the special exports had an annual value of from £92,000,000 to £348,000,000; the imports, from £210,000,000 to £512,000,000. The commercial intercourse with Great Britain is represented by exports thither to the amount of from £9,000,000

to £44,000,000 a year (woollen yarn, glass and glass-ware, hops, &c.), and by imports from Britain worth from £20,000,000 to £50,000,000 (iron and steel manufactures, cottons, cotton-yarns, oil-seeds, soap, &c.). The exports to Germany (normally) and to France and imports from both countries considerably exceed the British totals; the exports to Germany used to be nearly double.

Religion.—The Roman Catholic is the dominant religion. Although full liberty of worship is guaranteed to all, and the ministers of each denomination are paid by the state, almost the entire population are Roman Catholics, the number of Protestants being set down, when last ascertained (1891), at 27,900, of Jews at 13,200. The supreme Catholic dignitaries of Belgium are the Archbishop of Mechlin and the five diocesan bishops of Bruges, Ghent, Tournai, Namur, and Liège. There are numerous conventual houses and some beguinages. See *BEGUINES*.

Culture.—Diversity of language has retarded the growth of the national mind and the formation of an independent national literature to act as the bond of national unity. The Flemish element—the most important—has done much of late to foster the Flemish tongue, and if possible secure its predominance. Flemish theatres are supported in the great towns; a Royal Academy to encourage the study of its language and literature was opened at Ghent in 1886; in 1887 the king was constrained to make speeches in Flemish; in 1911 a Flemish university at Ghent was demanded. Official equality with French has been vindicated for Flemish. Against the disruptive tendency of the Dutch and French sympathies of the 'Flamingants' and the 'Fransquillons' the bond of a common religion has hitherto prevailed. Scientific and literary societies, museums, and libraries are numerous. There are many musical schools throughout the country, and great conservatoires at Brussels, Ghent, Liège, and Antwerp. Among the old musicians Jacob Clemens ('Clemens non Papa') and Orlando di Lasso were Flemings; and in later times Grétry, César Franck (a French citizen of German descent), and Ysaye have been natives of Liège, Vieuxtemps of Verviers, and Fétis of Mons. Painting and architecture formerly flourished in the wealthy old towns of Flanders; and although, after the brilliant epoch of Rubens and his pupils, a long period of dullness followed, in modern times a revival of art has taken place, and important academies have been founded at Antwerp and Brussels. For the achievements of the old Flemish school, see *PAINTING*, and the articles on RUBENS, TENIERS, VAN DYCK, &c.

The Belgian school-system has undergone many changes in modern times. In 1879 education in the public schools was completely secularised; but on the succession of a Catholic ministry in 1884 government support was withdrawn from these schools, and each parish had to decide whether its primary school should be continued at the parish's cost, or the children be sent to the church school. As a result numerous church schools have been recognised as public schools, the others having been abolished. There are state universities at Ghent and Liège, a 'Colonial University' at Antwerp, 'free' universities at Louvain (Catholic) and Brussels, 23 *Athénées* and colleges, about 150 middle-class and many private schools, and some Jesuit gymnasia. Yet in 1880 30·3 per cent., in 1900 19·1 per cent., and in 1910 13·1 per cent. of the inhabitants over eight years of age could neither read nor write.

Literature.—The Flemish literature of Belgium falls to be discussed under *HOLLAND (Language and Literature)*. Of modern authors in Flemish, Conscience the novelist, Willems the philologist, and the poets Guido Gezelle (1830-99) and Pol de

Mont are noteworthy. Of late, however, the main current of Belgian literary activity has run mainly in the channels of politics and modern national history, and in the French tongue. Historians are Pouillet, Moke, Namèche, Juste, and Kervyn de Lettenhove; Laveleye was a well-known publicist. Quételet, the statistician and astronomer, was a Belgian. Charles de Coster, author of *La Légende et les Aventures d'Ulenspiegel*; Camille Lemonnier, novelist; Maurice Maeterlinck, poet, playwright, and spiritual philosopher; Emile Verhaeren, poet; Max Elskamp, religious poet; Charles van Lerberghe, poet; Georges Rodenbach, miscellaneous writer; Georges Bekhoud, novelist; Eugène Demolder, tale-writer; and Emile Cammaerts, poet, are amongst the most important recent names in literature. Walloon literature, unlike French literature by Belgians, is of little value in itself. Dating from the end of the 17th century, it consists mainly of popular songs, satirical and humorous, and comedies. Of Walloon writers may be named Nicolas Defrecheux (1825-74), Delchei, and Isidore Dory.

Army.—The Belgian army has a peace-strength of about 50,000 men, raised in time of war to 200,000. It is intended solely for defence, and to preserve the neutrality of the territory; it is recruited partly voluntarily, partly by conscription, to which every healthy man who has passed his nineteenth year is liable. The legal period of service is eight years, but about six of these are, as a rule, passed on furlough. Then follow five years in the reserve. The importance of Belgium in a military point of view, and the length of its frontier towards Holland, Germany, and France, afforded a reason for the maintenance of fortifications at Antwerp, Dendermonde, Namur, Diest, Liège, Mons, Tournai, and Ypres, which the experience of the Great War proved to be helpless against modern artillery. The chief arsenal is at Antwerp.

Government.—The government of Belgium is a limited constitutional and hereditary monarchy, and was established in its present form by the revolution of 1830. The administration of justice is governed by the *Code Napoléon*. The legislative body consists of two chambers—the Senate and the Chamber of Representatives. Representatives are elected by the general body of citizens; senators partly directly by the citizens, partly by the provincial councils according to population, partly by the Senate itself. Certain princes are also senators. In 1919 a few women were allowed to vote, and various inequalities of the suffrage in respect of property, legitimate offspring, &c. were set aside in practice. Constitutional revision in 1920-21 legalised a system which is practically adult male suffrage. The suffrage for provincial and communal councils has also been liberalised.

See FLANDERS, and the articles on the several provinces; also Genonçaux, *La Belgique* (1879); Hymans, *La Belgique Contemporaine* (1880); Wauters, *La Belgique Ancienne et Moderne* (1882 et seq.); Scudamore, *Belgium and the Belgians* (1901); Van de Perre, *The Language Question in Belgium* (1919); Remy de Gourmont, *La Belgique Littéraire* (1915); Jethro Bithell, *Contemporary Belgian Literature* (1915); Albert Heumann, *Le Mouvement Littéraire Belge d'Expression Française* (1913); Maurice Gauchez, *Histoire des Lettres Françaises de Belgique* (1922); Pol de Mont, *Modernités* (a French anthology, 1911); Wilmette, *Le Wallon* (1893); Defrecheux, &c., *Anthologie des Poètes Wallons* (1895); Hamelius, *Histoire Poétique et Littéraire du Mouvement Flamand* (1894). *Onze Dichters*, published in 1880, is an anthology of the poets who, since 1830, had contributed to the revival of Flemish literature.

History.—The history of Belgium dates from 1830-31, when the Southern Netherlands parted from Holland and became an independent kingdom. The narrative prior to 1831 of the provinces forming

the present Belgium will be found in the article HOLLAND. But it may be well to introduce our account of Belgian history with a brief sketch of its previous development. On the downfall of the Roman empire, the *Gallia Belgica* of the Romans passed under the dominion of the Franks. As the feudal system arose, the country was distributed under a number of dukes and counts with a considerable measure of local independence. These provinces were absorbed by the great House of Burgundy from 1385 onwards, and they continued under that rule till the downfall of Charles the Bold in 1477. With his daughter Mary they then passed to the House of Hapsburg, and remained with the Spanish branch of that line till the peace of Utrecht in 1713, being known as the Spanish Netherlands to distinguish them from the northern provinces, which, in the reign of Philip II., had revolted from Spain, and formed a Protestant Republic, while the southern provinces continued subject to the Roman Catholic Church. In 1713, by the peace of Utrecht, the Spanish provinces were transferred from Spain to Austria, as the Austrian Netherlands. The country was conquered by Pichegru in the campaign of 1794, and subsequently united to France by the treaties of Campo-Formio and Lunéville. It now shared the fortunes of France during the Consulate and the Empire, received the *Code Napoléon*, and in all political relations was organised as a part of France. After the fall of Napoleon it was united with Holland under Prince William-Frederick of Nassau, and its boundaries were defined by the Congress of Vienna (May 31, 1815). In the campaign of 1815 Belgium was once again, as it had often been, the 'battle-field of Europe'; and Belgian troops were present at Waterloo.

The union of what had been the Spanish or Austrian Netherlands to Holland in 1815 was from the first an arbitrary one, as the people of the northern and southern parts of the united kingdom differed essentially in religion, language, interests, and historic feeling. Nor was the policy of the Dutch fair or conciliatory. The Dutch almost exclusively occupied the higher posts in the army and administration. The use of French in the southern provinces was discouraged, and the privileges of the Catholic clergy were curtailed. Old feelings of patriotism and the interests of self-government were equally disregarded. Thus, Liberals and Catholics were alike ready to revolt against Dutch supremacy, and the concessions tardily made to satisfy the growing discontent did no good. The outbreak of the French Revolution in 1830 set the example to the discontent across the frontier. On the king's birthday (August 24, 1830), several riots occurred in various towns of Belgium. At this period, however, the idea of separation from Holland does not seem to have presented itself consciously to the Belgian mind; the deputies who were sent to the Hague to state the causes of the general dissatisfaction merely insisted on Belgium's possessing a separate administration, with the redress of particular grievances. But the dilatory and obstructive conduct of the Dutch deputies in the States-general assembled at the Hague on the 13th September, together with the ill-advised occupation of Brussels by an army of 14,000 men, exasperated the Belgian nation beyond measure. A new and more resolute insurrection instantly took place. In seven days the people had deposed the old authorities and appointed a provisional government. Prince Frederick, the son of the Dutch king, who commanded the troops, was compelled to retreat from Brussels to Antwerp, having suffered considerable loss. On the 4th of October Belgium was declared independent by the provisional government. The useless bombard-

ment of Antwerp by the Dutch general Chassé (October 27) increased the bitterness of feeling, and rendered reconciliation wholly impossible. At the national congress of November 10, out of 200 votes only 13 were in favour of republican government. Meanwhile, the London Congress had assembled, and after mature deliberation, the representatives of Austria, Prussia, Russia, and England recognised the severance of the two kingdoms as a *fait accompli* (December 20). When the Belgian Congress met, it appointed Baron Surlet de Chokier provisional regent, but on June 4, 1831, it elected Prince Leopold of Saxe-Coburg king of the Belgians. Leopold entered Brussels on the 21st July, and subscribed the constitution. His marriage to a daughter of Louis-Philippe secured French support. Holland refused to acknowledge the validity of the decision of the London Congress, and declared war, which was speedily terminated by France and England—Holland securing that Belgium should annually pay 8,400,000 florins as interest for its share in the national debt of the Netherlands. And it was agreed by the powers that Belgium should remain an independent and perfectly neutral state. Holland, however, was still dissatisfied, and ventured to employ force. England and France were compelled to interfere. The French besieged and took Antwerp, still held by the Dutch troops; and the blockade of the coast of Holland having brought the Dutch to terms, the dispute was closed by a treaty signed in London, May 21, 1833.

In 1838 it seemed as if Holland and Belgium were likely to engage in war once more. According to the 'twenty-four articles' of the 'Definitive Treaty,' Belgium was under obligation to give up Limburg and a part of Luxemburg during the above-mentioned year. This it now refused to do, and put its army on a war-footing; but its obstinacy finally gave way to the unanimous decision of the five great powers, and on the 19th April 1839 a treaty of peace was signed at London, Belgium's annual share of the Netherlands' debt being at the same time reduced to 5,000,000 florins; and both Limburg and Luxemburg being partitioned between Holland and Belgium.

After 1840 the opposition of the Catholic to the Liberal party became more and more decided, the educational laws not being satisfactory to the clergy, until, in July 1845, the liberal Van de Weyer endeavoured to confirm the so-called 'union' of the two parties. In 1846 a purely Catholic ministry took office; but in 1847 a liberal ministry was formed by Rogier. The revolutionary tempest of 1848 menaced the tranquillity of the country; but the king disarmed hostility by promptly declaring himself ready to retain or to surrender the crown of Belgium, according to the decision of the people.

In July 1848 the elections greatly strengthened the liberal-constitutional party, and in 1850 the educational question was supposed to be settled on soundly liberal principles; but since then there has been a keen and continued struggle between Progressists and Ultramontanes, the balance of power shifting from time to time. Thus liberal ministries were continuously in power from 1857 to 1864, and in 1878 (under Frère-Orban); clerical ministries in 1870, 1876, 1880, and 1884, the educational question being the chief bone of contention. On the death of Leopold I. in 1865, his son had succeeded as Leopold II. In 1867 Belgium took part in the London conference for settling the Luxemburg question, which threatened to plunge Europe in war, but did not sign the guarantee for the neutrality of Luxemburg. On the outbreak of the Franco-German war in 1870, the Belgians fearing risks both from Prussia and from France, mobilised their army; but in a special treaty

arranged by Britain, both belligerents recognised anew the neutrality of Belgium, guaranteed in 1831 and 1839. In 1885 the Congo Free State was acknowledged by the powers, under the king of Belgium's presidency; its internal management was long the subject of bitter controversy at home and abroad; and in 1907-8 it was annexed to Belgium as Belgian Congo (see CONGO). On the death of Leopold II. in 1909 he was succeeded by his nephew Albert. Political strife about the suffrage led to a revision of the constitution, which in 1900 gave the Catholics a large majority. Since then Socialists and Liberals have secured power by help of proportional representation. A principal sufferer in the Great War (q.v.), Belgium was at once invaded by the Germans, and almost the whole of its territory occupied to the end of the war. The peace added Moresnet, Malmédy, and Eupen to Belgium. Recovery was rapid, but Belgium was involved in the general confusion of Europe. Constitutional revision was undertaken. A military alliance with France, and an aggressive attitude towards Holland and Luxemburg, was the policy of the government till the elections of 1921, when the Socialists went into opposition against a Catholic-Liberal coalition. In 1922 a fifty years' economic union with Luxemburg came into force.

See the works by Juste (4th ed. 1868), Moke (7th ed. 1881), Hymans (5 vols. 1880), D. Boulger (1913), and Cammaerts (1921 and 1924).

Belgorod (Russian *Byelgorod*, 'white town'), a town on the Donetz, 360 miles S. of Moscow, is an archbishop's see, has many churches, manufactures leather, soap, and woollens, and trades in wax, bristles, and hemp; pop. 26,000.

Belgrade (Serb. *Beograd*, 'white town'), an important fortified city, the capital of Serbia and of Yugoslavia, lies opposite Semlin, at the confluence of the Save and Danube. The walls have disappeared since 1862; the last and finest of the five gates was demolished in 1868; the old fortress still crowns the hill. The town has lost its old Turkish aspect, and become quite modern and European. There is a vigorous university. The royal palace, the residence of the metropolitan, the national theatre, the Orthodox cathedral, and the public offices are the principal buildings. Opposite the theatre is a bronze monument (1882) to the murdered Prince Michael III. Belgrade has but tiffing manufactures. It is, however, the natural entrepôt of the trade between central Europe and the Balkans. Pop. (1872) 26,674; (1910) 90,890; (1920) 111,740. Belgrade is the *Singidunum* of Ptolemy. Its position made it the chief point of communication between Constantinople and Vienna, and the key to Hungary on the south-east. It has consequently been the scene of many hard-fought contests. The Greeks held it until 1073, when it was captured by the Hungarian king, Salomon. After this it passed through the hands of Greeks, Bulgarians, Bosnians, and Serbians, and these last proprietors sold it in 1426 to the Emperor Sigismund. In 1440 it was unsuccessfully besieged by the Turks, with a large and vain outlay of time and money; and when stormed (1456), was retaken from the Turks by the heroism of Hunyadi and Capistrano. In 1522 it was carried by the Sultan Soliman II. In 1688 it was stormed and taken by Maximilian, Elector of Bavaria; but in 1690 was recaptured by the Turks, when the Christian garrison had been reduced to 500 men. In 1692 Belgrade was vainly besieged by the Duke of Croy; and in 1717 the citadel surrendered to Prince Eugene, after he had defeated an army of 200,000 Turks, with a loss to them of 20,000 men. But in 1739 Belgrade again changed owners, the Turks obtaining it without a shot. In conformity

with the treaty then signed, the fortifications were demolished. In 1789 it was again taken by the Austrians under General Laudon, but by the treaty of peace (1791) was restored to the Turks. From 1806 to 1812 it was in the possession of the insurgent Serbians; and in 1862, after a wanton bombardment from the citadel, it was made the capital of the principality of Serbia, though the citadel remained in the hands of the Turks till 1867. It was taken by the Austrians 2d December 1914, recovered on the 14th, taken again by Austrians and Germans 9th October 1915; and the Serbs re-entered 1st November 1918. It became capital of the new Serb-Croat-Slovene state. The Archbishop of Peč, Belgrade, and Karlovci is Patriarch of the Serbian (Orthodox) Church. The Concordat of 1914 between Serbia and Rome provides for a Roman Catholic Archbishop of Belgrade. See SERBIA, and books there noted.

Be'li'al, or, more accurately, *Beli'al*, a Hebrew word, often treated by the translators of the authorised version as a proper name, but really an abstract term meaning 'that which is without use or profit,' 'worthlessness,' hence 'wickedness.' It is mostly used in the forms 'son of Belial,' 'man of Belial;' but the adjunct is often omitted, and the word stands by itself as a term of reproach.

Belief is a term which is sufficiently definite for most ordinary purposes; but it is used with some variety in meaning, and psychologists do not always agree in the tests they give for distinguishing belief from other states of mind. The word is used to mean the acceptance of a proposition, statement, or fact as true on the ground of evidence, authority, or irresistible mental predisposition; the state of trust in and reliance on a person, thing, or principle; as also for the fact believed, and sometimes specifically for the apostles' creed. Belief is by some distinguished from knowledge, inasmuch as the latter rests on evidence, while belief rests on authority. Belief should, some say, not be used of facts such as are occurring in one's own experience, or principles of which the opposite implies absurdity, such as the axioms of geometry. These we *know*; and according to this view, the term should be limited to cases where a proposition is accepted without evidence, or where such evidence as is available implies only probability. On the other hand, the psychologists of what is called the intuitive school are accustomed to regard as beliefs the fundamental data on which reasoning rests; and to say that all knowledge rests ultimately on belief. Belief, they say, may admit of all degrees of confidence, from a slight suspicion to full assurance. There are many operations of mind in which it is an ingredient—consciousness, remembrance, perception. Kant defined *opinion* as a judgment which is insufficiently based, subjectively as well as objectively; *belief*, as subjectively sufficient but objectively inadequate; *knowledge*, as both subjectively and objectively sufficient. The strongest beliefs may of course be false; beliefs in ghosts, astrological prognostications, &c., are usually treated as superstitions. Beliefs as such rest on grounds regarded as sufficient by the person believing, who is prepared to act on his belief; but their grounds may have absolutely no validity for any other person. Such beliefs are nevertheless very real. On the other hand there are many propositions accepted traditionally, and spoken of as beliefs, which are not real vital abiding truths for those who nominally accept them; which have no influence on character or mental tone, and on which those who hold them would not be prepared to act. Faith is a word used in very much the same sense as belief, but specially signifies the acceptance of and reliance on the truths of religion.

For this use, see the articles FAITH, IMMORTALITY.

Belisarius (Slav. *Beli-tzar*, 'white prince'). This heroic and loyal soldier, to whom the Emperor Justinian was principally indebted for the glory of his reign, was born at Germanica, in Illyria, about 505 A.D. Appointed to the command of the eastern army of the empire, stationed on the confines of Persia, he gained in 530 a victory over a Persian army nearly twice as large as his own. In the following year, when the Persians had penetrated into Syria, Belisarius was compelled by the impatience of his troops to offer battle at Callinicum on the Euphrates, and his defeat was followed by his recall. He still remained, however, the firm supporter of his sovereign. In Constantinople, the strife of the two parties, styled the 'Green' and the 'Blue,' had endangered the authority and even the life of Justinian; already a new emperor, Hypatius, had been elected, when Belisarius attacked and slew in the hippodrome 30,000 of the Green or anti-loyalist party, and thus restored tranquillity. Prior to this he had married a wealthy but profligate lady, Antonina, whom he loved with blind uxoriousness.

The military career of Belisarius may be divided into two great epochs—the war against the Vandals in Africa, and the war against the Goths in Italy. The first of these epochs was commenced by Justinian sending Belisarius in 533 with an army of 15,000 men into Africa, in order to recover the provinces there held by the Vandal king, Gelimer. After achieving two victories, Belisarius made the king a prisoner, seized his treasures, and conquering Sardinia, Corsica, and the Balearic Isles, brought him to Constantinople, where he appeared in a triumphal procession of the conqueror—the first that a subject had enjoyed since the days of Tiberius. The African Vandals never recovered from this overthrow. Medals were struck in Belisarius's honour; and on the 1st January 535 he was invested with the dignity of 'consul.' The second war was occasioned by Justinian's attempt to wrest Italy from the hands of the barbarians. In 535 Belisarius conquered Sicily; and in the autumn of 536 he occupied Lower Italy. He entered Rome by amicable arrangement with the inhabitants; and finding his forces not strong enough to contend with the Goths in open field, he allowed himself to be besieged for a year, when the siege was raised by the Goths. In 538 Narses had been sent with a reinforcement for the army in Italy; but some misunderstanding occurring between the two generals, they were prevented from relieving Milan, which in 539 was carried and devastated by Braias, nephew of the Gothic king, Vitiges. Consequently, Narses was recalled from Italy; and Belisarius, now placed at the head of both armies, refused to assent to a treaty proposed by Justinian's ambassadors to Vitiges, who had persuaded the Persian king, Chosroes, to invade the eastern Roman territory. Belisarius drove the Goths back to Ravenna, which he captured in 540, along with Vitiges himself. But before he could complete his conquest of the Goths, he was recalled by Justinian to Constantinople. In 541–542 he was engaged in a campaign against the Persians, who had captured Antioch; but was again recalled on account of slanderous representations. His second great struggle with the Ostrogoths now begins. In 544 the barbarians under Totila again invaded and reconquered Italy. Belisarius was sent against them, but with an insufficient army. He, however, maintained his ground for five years, and even succeeded so far as to regain possession of Rome. But in spite of his repeated entreaties, no reinforcements were sent

to him; and in 548 he gave up the command, his rival, Narses, being appointed in his place. In 559, after ten years of retirement, Belisarius once more came forward at the head of an army hastily collected, and overthrew the Bulgarians who were threatening Constantinople. Here this faithful servant, who at Ravenna had refused the crown of Italy offered to him by the Goths, was at length accused of a conspiracy against Justinian, and imprisoned (563); but Justinian, becoming convinced of Belisarius's innocence, restored him after six months to all his honours. He died in 565. Tzetzes, in the 12th century, was the first to aver that, during his half-year's imprisonment, Belisarius suspended a bag from the window of his cell, and exclaimed to those who passed by: 'Give an obolus to Belisarius, who rose by merit, and was cast down by envy!' Lord Mahon, in his *Life of Belisarius* (Lond. 1829), endeavours, but without success, to confirm the tradition of Belisarius being deprived of sight and reduced to mendicancy—a fiction given in Marmontel's romance, which supplied the painter Gérard with the subject for a fine picture. See Hodgkin's *Italy and her Invaders* (1880-85).

Belize', or **BRITISH HONDURAS**, a British colony washed on the E. by the Bay of Honduras, in the Caribbean Sea, and elsewhere surrounded by Guatemala and Mexico. It forms the south-east part of the peninsula of Yucatan, and measuring 180 by 60 miles, has an area of 8600 sq. m. Pop. 45,000. The river Belize traverses the middle of the country, and the Rio Hondo and the Sarstoon form its north-western and its southern boundary. The Cockscorn Mountains (4000 feet) are the highest eminences, the land all along the coast being low and swampy. The country, of tropical fertility, produces mahogany, cedar, logwood, sugar, coffee, cotton, sarsapilla, bananas and plantains, rubber, coconuts, rum, chicle, cacao, pine-apples, oranges, mangoes, and other fruits. Sponges and tortoise-shell are obtained. The exports are partly the produce of Mexico and Guatemala. The name Belize is probably a Spanish corruption of the name Wallis, one of the early British settlers; otherwise it is usually referred to the Fr. *balise*, 'a beacon.' Those early settlers, buccaneers at starting, then logwood-cutters, were frequently attacked by the Spaniards; but after 1798, when they repulsed a fleet and a land-force of 2000 men, their occupation was formally acquiesced in. Since 1862 Belize has ranked as a British colony, with a lieutenant-governor, whose rank was raised in 1884 to that of governor. Belize, the capital, is a depôt for British goods for Central America, and has a pop. of about 13,000. See books on British Honduras by Gibbs (1883), Bristowe and Wright (1892), Metzgen and Cain (1925).

Bell. Though there has been some variation from time to time in the substance of which bells are formed, yet in all ages the best-approved has been a mixture of copper and tin called bronze. The proportions of the metals are by no means the same in all cases. The small bells found by Layard in the palace of Nimrud contain 10 parts of copper to 1 of tin; but such an excess of the former metal is rare, and 2 to 1 was for ages in Europe a more approximate ratio. For instance, in the reign of Henry III., 1050 lb. of copper and 500 lb. of tin were allowed, together with old bell-metal, for casting three bells for Dover Castle. The tendency of after-ages has been to increase the proportion of copper, which is stated on good authority to be in the ratio of 13 to 4 to the tin. Of late, steel bells have been cast in Sheffield by Riepe's patent, but these have a less sustained vibration, which is also the result of attempting to

extract from a specified amount of bronze a deeper note than it is fairly capable of affording. The fragility of glass bells will prove a serious obstacle to their use, whatever beauty there may be in their sound. As to hand-bells, crotals, and the like, they have been made of almost endless variety of material. Silver, however, is always injurious to the tone of any bell, great or small, and it is only the eye which feels pleasure from these little instruments. An elegant specimen of a silver-gilt hand-bell, which belonged to Mary, Queen of Scots, was exhibited in the year 1887 at Peterborough among a number of other objects connected with that unhappy queen. The pitch of a bell is regulated by the thickness of the striking-place in proportion to the diameter, the ratio being about 1 to 12 in a bell of 10 cwt. Some medieval bells of good tone are remarkable for the thinness of the sound-bow.

Queen Mary's Hand-bell.

From a remote antiquity cymbals and hand-bells were used in religious ceremonies. In Egypt we find that the festivals of Isis were celebrated with the sound of *sistra*, apparently small crotals. Aaron and other Jewish high-priests wore golden bells attached to their vestments; and the priests of Cybele used cymbals in their rites. The Greeks employed bells of some kind (*kōdōnes*) in camps and garrison; and the Romans announced the hour of bathing by the *æs thermarum*. Great uncertainty prevails as to the introduction of bells into Christian churches. Suetonius relates that Augustus Caesar placed *tintinnabula* round the top of the temple of Jupiter Tonans; and it is possible that when basilicas and other buildings came into the possession of the church in the reign of Constantine the Great, the bells belonging to them were readily adapted to the purpose of calling together congregations. The ascription of the first use of bells for church purposes to Paulinus, Bishop of Nola in Campania, appears to rest mainly on the names *Nola* and *Campana*, which are commonly given to bells. *Nola*, however, is a word in use long before the time of Paulinus, and hardly likely to be taken from the name of a city without modification. The derivations of both words are probably not local. Bells appear to have been introduced into France about 550; and Benedict, abbot of Wearmouth, is related to have brought one from Italy for his church about 680. Bells came into use in the Greek Church in the 9th century, and in Switzerland and Germany in the 11th. Most of the bells first used in Western Christendom seem to have been hand-bells. Several specimens, some of them, it is believed, as old as the 6th century, are still preserved in Ireland, Scotland, and Wales. They are made of thin plates of hammered iron, bent into a four-sided form, fastened with rivets, and brazed or bronzed. Perhaps the most remarkable is that which is said to have belonged to St Patrick, called the *Clog-an-eadhachta Phatraic*, or 'The bell of Patrick's Will.' It is 6 inches high, 5 inches broad, and 4 inches deep, and is kept in a case or shrine of brass, enriched with gems and with gold and silver filigree, and was made (as an inscription in Irish shows) between the years 1091 and 1105. The bell itself is believed to be mentioned in the *Annals of Ulster* as early as the year 552. Engravings as well of the bell as of its shrine, with a

history of both, by the Rev. Dr Reeves of Lusk, were published at Belfast (where the relic is preserved) in 1850. The

Ancient Bell from Brittany.

accompanying cut shows an ancient specimen of this type from Brittany. Some of the Scottish bells, of the same primitive type, are figured and described in Dr Joseph Anderson's *Scotland in Early Christian Times* (Rhind Lectures, Edin. 1881). The four-sided bell of St Gall, an Irish missionary who died about 646, is still shown in the monastery of the city which bears his name in Switzerland. Church-bells were suspended either in the steeples or church-towers, or in special bell-towers. They were long of comparatively small size: the bell which a king presented to the church of Orleans in the 11th century, and which was remarkable in its age, weighed only 2600 lb. In the 13th century much larger bells began to be cast, but it was not until the 14th century that they reached really considerable dimensions. The bell 'Jacqueline' of Paris, cast in 1400, weighed 15,000 lb.; another Paris bell, cast in 1472, weighed 23,000 lb.; the famous bell of Rouen, cast in 1501, weighed

Great Bell at Moscow (from a Photograph).

36,364 lb. The largest bell in the world is the Great Bell, Monarch or Czar Bell (*Tsar Kolokol*), of Moscow. It is 19 feet high, 60 feet round the rim, and weighs 198 tons. Cast in 1653, it came cracked out of the foundry, and never was hung. In 1837 it was raised on a granite basement, and makes a kind of chapel, the broken side forming the doorway. Another Moscow bell, the largest in use, weighs 128 tons. The Great Bell at Pekin weighs 53½ tons; the 'Kaiserglocke' of Cologne Cathedral (1887; melted 1918), 14½ feet high, 11½ in diameter, made of 22 French cannon, weighed 26 tons 13 cwt.: its successor, the St Peter's Bell, weighs 25 tons; those of Olmütz, Rouen, and Vienna weigh nearly 18 tons; that first cast for the new palace at Westminster (but cracked), 14 tons; that of the Roman Catholic cathedral at Montreal (cast 1847), 13½

tons; 'Great Peter,' placed in York Minster, 1845, 10½ tons; 'Great Tom' at Christ Church, Oxford, a faulty bell, cast in 1680, 7½ tons; 'Great Tom' at Lincoln, cast in 1834, 5½ tons; the Great Bell at St Paul's, cast in 1881, 17½ tons; the church of the Sacred Heart at Montmartre, close on 19 tons. Many of these weights, however, have been imperfectly verified. See Gatty's *The Bell* (1848), Stainer's *Great Paul* (1882), North's *English Bells and Bell-lore* (1891), Raven's *The Bells of England* (1906), Walters's *Church Bells of England* (1913).

Associated in various ways with the ancient ritual of the church—inasmuch that Mohammedanism (q.v.) rejects the use of bells and substitutes the muezzin's cry—bells acquired a kind of sacred character. They were consecrated by a complete baptismal service; received names, had sponsors, were sprinkled with water, anointed, and finally covered with the white garment or chrisom, like infants. This usage is as old as the time of Alcuin, and is still practised in Roman Catholic countries. Bells had mostly pious inscriptions, sometimes indicative of the widespread belief in the mysterious virtue of their sound. They were believed to disperse storms and pestilence, drive away enemies, extinguish fire, &c. The mediæval inscription, 'Voce mea viva depello cuncta nociva,' is still frequently found on bells in the west of England. Among the superstitious usages recorded to have taken place in old St Paul's Church in London, was the 'ringing the hallowed belle in great tempestes or lightnings.' The strange notion that bells are efficacious in dispelling storms is by no means extinct.

Church-bells were at one time tolled for those passing out of the world, in order that the people might put up their prayers for the dying person, as we learn from the *Rationale* of Durandus. The tolling of the passing-bell was retained at the Reformation; nor do the Puritans seem to have objected to the practice, as, for instance, when Dr John Rainolds was dying, 'he expressed by signes that he would have the passing bell tole for him.' But by the beginning of the 18th century, the passing-bell, in the proper sense of the term, had almost ceased to be heard; the tolling took place after the death, instead of before. The practice of slowly and solemnly tolling church-bells after deaths, and before funerals, is still an established usage throughout England. The *Pardon*, *Gabriel*, or *Ave bell*, prior to the Reformation, was rung at morning, noon, or evening, or before or after service, inviting to the recitation of the salutation of the angel Gabriel, *Ave Maria, gratia plena, Dominus tecum*, for purposes of intercessory prayer, or the forgiveness of personal sins. The Ave bell was generally one of the ring dedicated to the angel Gabriel, and bearing on it the words of the Annunciation; but any bell might serve the purpose. The *Sanctus* or *Sacring bell*, rung at the Sanctus in the mass and at the elevation of the host, was often hung in a place by itself, usually on the gable at the east end of the nave; but a small hand-bell is now usual. *Vesper-bell*, properly the bell that summons to Vespers (q.v.), is usually a popular phrase for a bell rung at evening. Bishop Burnet has recorded the order of Bishop Shaxton of Sarum in 1538, concerning the discontinuance of the custom.

The ringing of the *curfew-bell*, supposed to have been introduced into England by William the Conqueror, was a custom of a civil or political nature, and only strictly observed till the end of the reign of William Rufus, the statute being abolished by Henry I. in 1100. Its object was to warn the public to extinguish their fires and lights at eight o'clock in the evening. The eight o'clock ringing is still continued in many parts of England and Scotland.

On all that belongs to the playing of bells in belfries, the inventive genius of the Netherlands long since arrived at proficiency. In some of the church-towers of that country, the striking, chiming, and playing of bells is incessant; the tinkling called chimes usually accompanies the striking of the hours, half-hours, and quarters; while the playing of tunes comes in as a special divertisement. In some instances, these tune-playing bells are sounded by means of a cylinder, on the principle of a barrel-organ; but in others, they are played with keys by a musician. The term *carillon* is used either of the tune played on bells, or of the suite of bells which yields this kind of music. The tower of Les Halles, at Bruges, is allowed to have the finest in Europe (see BELFRY, CAMPANILE).

Many of the church-towers throughout England, in villages as well as in towns, are provided with peals of bells, the ringing of which is a well-known practice. The number of *changes* or permutations of order that can be rung on a peal, is the *factorial* of the number of bells—i.e. the continued product of all the natural numbers from unity to the number of bells. Thus 3 bells allow 6 changes; 4 bells, 24; 8 bells, 40,320; 12 bells give as many as 479,001,600 changes. The ringing of peals differs entirely from chiming or tolling.

There is no method of sounding bells equal to the English ringing, when the bell at each pull revolves round a complete circle, and is under the full command of the ringer. This power over the bells makes the sequence of sounds to be regulated at the will of the band of performers, each of whom has his bell, while the leader 'calls' the peal. It is of course necessary that strict order should be observed in arranging the changes, for no unassisted memory would carry a ringer far into the peal. Also, from the nature of bell-machinery, a certain time must elapse between two strokes of the same bell, to allow for its swinging round. The first known writer on the subject is Fabian Stedman, a Cambridge printer, whose *Tintinnologia* was published in 1668. He is said to have printed his changes on slips of paper in his leisure hours, and taught them to his company in the tower of St Benedict, Cambridge. According to his account, there was no idea of change-ringing till the beginning of the 17th century, though there certainly seem traces of it in Udall's *Ralph Roister Doister*, which was written in 1553. Once started, the art made rapid progress, and rings of bells increased from five or six to ten and twelve, the latter being the greatest number ever rung in peal. The simplest peals are those called *Grandsire* on an odd number of bells, and *Bob* on an even number. Thus, changes on seven bells, with the tenor, or great bell, sounded last in each change, are called *Grandsire Triples*; on nine, *Grandsire Caters*; and on eleven, *Grandsire Cinques*; while on six, eight, ten, or twelve, the more usual methods are respectively *Bob Minor*, *Bob Major*, *Bob Royal*, and *Bob Maximus*. There are, however, a variety of other methods of producing the changes, known as *Oxford Treble Bob*, *Norwich Court Bob*, &c. The muffled peal, which is an invention of later days, is rung with a leather cap over half of the chapper, thus rendering the chimes alternately clear and dull. The effect is very fine.

The general method of making bells has not varied much for centuries, though constant modifications in detail have come into vogue. A core of brickwork covered with soft clay is moulded to the intended form of the inner surface of the bell by means of a curved compass called a *crook*, and in a similar way the form of the outer surface is moulded on the inside of the outer mould, or *cope*. The cope is fitted over the core, with a hole left at the

top for the escape of the air, and the metal in a state of fusion is admitted to fill the space intervening between the cope and the core (see CASTING).

The art of casting bells in sequence of sound appears to have been practised after the Conquest, partly by ecclesiastics, and partly by handicraftsmen, who produced bronze lavers, mortars, and after a time cannons, as well as bells. Walter of Odington, a monk of Evesham, in the time of Henry III., has given careful directions for producing a tunable ring, and Sandre (or Alexander) founder of Gloucester, shortly afterwards, was an ecclesiastic. By the end of the 14th century the work appears to have fallen entirely into the hands of laymen; and excellent bells of the period from that time to the Reformation from the foundries in Norwich, Bury St Edmunds, York, Leicester, and other centres, remain in abundance all over England. Nor has the general form of the bell undergone much change since that time. The late 'Tom of Lincoln,' weighing a ton less than the present bell, was cast in the Minster Yard in 1610 by the joint efforts of Henry Oldfield of Nottingham and William Newcombe of Leicester. The bells made by Miles Graye of Colchester, who died in 1649, are deservedly much esteemed by ringers. Louvain, lately famous under M. Severin van Aerschodt, has produced many excellent bells, great and small, since the days of the Van den Gheyns, nearly four centuries ago. A few medieval bells from Venlo are still found in England. The twelve bells of Christ Church, Oxford, are renowned for their tone; the largest peal in England is that of St Paul's (12 bells, the tenor weighing 64 cwt.).

Rings of bells other than carillons are apparently unknown on the Continent, but in every considerable town fine-toned large bells are to be found, sometimes in sequence though in different churches. Very few old bells remain in France, some districts having been entirely cleared of them in the time of the first Napoleon.

The tubular bells of Harrington of Coventry are steel tubes, varying in length from 4 or 5 to 12 or 14 feet, suspended in a frame in the belfry by means of cords passed through holes in the upper part of each tube, and struck by a hammer above the point of suspension. Since 1896 a revolution has been brought about in the tuning of bells, largely through the efforts of Canon Simpson of Fittleworth, in Sussex; and there is now no reason why every bell should not give out a true and harmonious chord instead of (as frequently) a collection of discords.

Bells have been much used in orchestral music, both singly and in the glockenspiel, a set of bells tuned in scale and played by a keyboard or otherwise. A frame containing a series of metal tubes is now commonly used. In Belgium musicians like M. Josef Denyn of Mechlin perform on the caillon.

The custom of hanging bells on the necks of horses, cows, and other animals, was in use by the Romans, and still survives in Switzerland and elsewhere. The bells are useful in the dark, or when the animals that wear them are out of sight. The attaching of small spherical bells or crotals to riding and sleigh-horses is common in some parts of Europe and America. These crotals used for this purpose are often exactly like those found in British graves, which were suspended on the spear of the warrior.

Ancient Crotal.

The *hanging of bells* in dwelling-houses, and ringing them by means of wires from the different apartments, is quite a modern invention; for it was not known in England in the reign of Queen Anne.

More recently, electric bells have been introduced. A galvanic battery requiring attention only at long intervals is used. From this an insulated wire goes to a 'press-button' in a room or elsewhere, thence to the bell, and back to the battery to complete the circuit. The press-button makes contact when one requires to ring; at other times the current is broken. Beside the bell there is an electromagnet, with an arrangement by which a spring is attracted and released in rapid succession as long as the automatically interrupted current of electricity is passing. This spring carries a knob which strikes the bell as it oscillates to and fro. An index is used when the bell is rung by press-buttons from several rooms.

The best-known earlier campanologists are Hieronymus Magius (Girolamo Magi, an Italian jurist), Pacicelli, and Stockfleth. Among later English writers, Lord Grimthorpe (Mr Beckett Denison, Q.C.) approached the subject from the side of acoustics, while Messrs Ellacombe, North, Stahl-schmidt, and others have investigated the archaeology of the bells of several districts in England. Schiller's famous *Song of the Bell*, Poe's *Bells*, and Hauptmann's play *Die Versunkene Glocke* may be mentioned as notable amongst poems on the subject.

Bell, book, and candle is a phrase descriptive of certain symbolic ceremonies accompanying Excommunication (q.v.). The book from which the sentence was read was slung, a candle dashed to the ground and extinguished, and a bell rung, with some such words as 'Do to the book, quench the candle, ring the bell.'

To bear the bell—that is, to take the first place—may allude to the bell worn by the leader of a herd or flock, or to a bell given as a prize, or confusedly to both.

'BELLS,' on shipboard, is explained at WATCH. In foggy weather both steamers and sailing-vessels when at anchor sound their bells (see FOG-SIGNALS).

Bell, ACTON. See BRONTË.

Bell, ALEXANDER MELVILLE, was born at Edinburgh in 1819, and there established himself as a teacher of elocution. In 1865 he removed to London, where, two years later, he published his work on *Visible Speech* (q.v.). He had been engaged for more than twenty years in perfecting his phonetic system; and with a view to bring it before the world, he visited the United States in 1868, and delivered a series of lectures, with such success that, in 1870, he removed to America, and finally settled in Washington, where he died 5th August 1905. He there published several books on phonetics, including his *Principles of Phonetics*. Among his earlier writings may be noted an ingenious system of *Steno-Phonography* (1854).—His son, **ALEXANDER GRAHAM BELL**, the inventor of the telephone, was born at Edinburgh in 1847, and was educated at the High School and University there, and at University College, London. He removed to Canada and the United States, and at Boston devoted himself to the teaching of deaf-mutes, and to spreading his father's system of 'Visible Speech,' and was professor of vocal physiology. His inventions of the articulating Telephone (q.v.) in 1872-76, of the Photophone (q.v.) in 1880, of the Graphophone (resembling Edison's Phonograph, q.v.) in 1887, and of kindred instruments brought him wealth and fame, numerous honours and degrees being bestowed on him in America and Europe. Aeronautics and eugenics also interested him. He died 2d August 1922.

Bell, ANDREW, D.D., founder of the 'Madras System of Education,' was born at St Andrews, 27th March 1753, and educated at the university of that place. After acting as a tutor in Virginia (1774-81), he took orders in the Church of England, sailed for India in 1787, and within two years was appointed to eight army chaplainships, all of which he managed to hold simultaneously. In 1789 he became superintendent of the Madras Orphanage for the sons of soldiers. Finding it impossible to obtain the services of properly qualified masters, he at length resorted to the expedient of conducting the school by the aid of the scholars themselves. Hence originated the far-famed 'Monitorial System' (q.v.). The state of his health forced him to return to England, where, in 1797, he was pensioned by the East India Company. His pamphlet entitled *An Experiment in Education, made at the Male Asylum of Madras* (1797), attracted little attention, until Joseph Lancaster (1778-1838), a Quaker, commenced to work upon the system, and succeeded in obtaining for it a large measure of public recognition. In 1803 Lancaster also published a tractate on education, recommending the monitorial system, as it was now called, and admitting Bell to be the original inventor of it, an admission which he afterwards discredibly retracted. Lancasterian schools now began to spread over the country. The church grew alarmed, and in 1811 founded the 'National Society for the Education of the Poor,' of which Bell was appointed superintendent, the number of its schools soon increasing to 12,000. He made a journey to the Continent in 1816 to spread his ideas, when he met Pestalozzi. Wordsworth, Coleridge, and Southey, who all had faith in the system, encouraged Bell; but it was found that although powerful service had been rendered to education by its aid, many evils, such as ignorance and inefficiency on the part of teachers, had also resulted from the system. Rector of Swanage till 1809, Bell then was made master of Sherburn Hospital, Durham, and in 1818-19 a prebendary of Hereford and of Westminster. He died at Cheltenham, 27th January 1832. He left (besides a valuable estate) £120,000 for the purpose of founding educational institutions. Half of this was to go to St Andrews, the other half to be equally divided between Edinburgh, Glasgow, Leith, Aberdeen, Inverness, Cupar, and the Royal Naval School, London. See his *Life* by Southey (3 vols. 1844), and Meiklejohn's *An Old Educational Reformer* (1881).

Bell, SIR CHARLES, an eminent surgeon, whose discoveries in the nervous system have given him a European fame, was born at Edinburgh in 1774, the youngest of five sons of William Bell, a clergyman of the Episcopal Church in Scotland. Three of his brothers became professors, the eldest, Robert, filling the chair of Conveyancing in Edinburgh from 1800 to 1816; John and George Joseph are separately treated. While a mere youth, Charles assisted his brother John in his anatomical lectures and demonstrations. In 1799 he was admitted a member of the Edinburgh College of Surgeons; in 1804 he proceeded to London, where for some years he lectured with great success on anatomy and surgery at the academy in Great Windmill Street. In 1807 he made the discovery, which he established by the publication of his *Anatomy of the Brain* (1811), of the existence of sensory and motor nerves in the brain; his investigations were completed between 1821-29, and included researches on the cranial nerves, which are embodied in his *Nervous System* (1830). These discoveries in physiology have been described as the greatest since Harvey demonstrated the circulation of the

blood. Appointed in 1812 surgeon to the Middlesex Hospital, a few years later he became a member of the Royal College of Surgeons, London; in the former institution he delivered clinical lectures, and raised it to the highest repute. To obtain a knowledge of gunshot wounds, he twice relinquished his London engagements—first after the battle of Corunna in 1809, when he visited Haslar Hospital; next after Waterloo, when he repaired to Brussels, and was put in charge of a hospital. In 1824 he was appointed senior professor of Anatomy and Surgery to the Royal College of Surgeons, London, and subsequently a member of the council. On the establishment of the London University, now University College, in 1826, Bell was placed at the head of their new medical school, but soon resigned, and confined himself to his extensive practice, which was chiefly in nervous affections. In 1829 he received the Royal Society's medal for discoveries in science. In 1831 he was knighted on the accession of William IV. In 1836 he was elected professor of Surgery in the university of Edinburgh. He was a Fellow of the Royal Societies of London and Edinburgh, and a member of some other learned bodies. He was editor, jointly with Lord Brougham, of *Paley's Evidences of Natural Religion*. He died suddenly, 28th April 1842, at Hallow Park, Worcester, where he was staying, and was buried in the churchyard there. Of a cheerful disposition, Bell enjoyed literature and music; fishing was a favourite recreation with him. Among his principal works on surgery and the nervous system are: *Anatomy of the Brain*, 12 plates (1802); *Engravings, explaining the Course of the Nerves* (1804); *Anatomy of Expression in Painting* (1806; posthumous edition, enlarged, 1844); *A System of Operative Surgery* (2 vols. 1807-9); *Gunshot Wounds* (1814); *Anatomy and Physiology of the Human Body* (3 vols. 1816); various papers on the nervous system, which originally appeared in the *Philosophical Transactions*; *Nerves of the Human Body* (1824); *Injuries of the Spine and of the Thigh Bone* (1824); *Institutes of Surgery* (1838); *Animal Mechanics*, contributed to the Library for the Diffusion of Useful Knowledge (1828); *Nervous System of the Human Body* (1830, 4to); *Practical Essays* (1841). *The Hand* (1833) is one of the celebrated *Bridgewater Treatises*. See Pichot's *Vie et Travaux de Sir Charles Bell* (1859), and his *Correspondence* (1870).

Bell, CURRER and ELLIS. See BRONTË.

Bell, GEORGE JOSEPH, an eminent lawyer, a brother of Sir Charles, was born at Edinburgh, 26th March 1770, and passed advocate in 1791. Acknowledged one of the greatest masters of commercial jurisprudence of his time, and in particular of that department of it which relates to the laws of bankruptcy, he was in 1822 appointed professor of Scots Law in Edinburgh University, and in 1823 a member of the commission for inquiring into Scottish judicial proceedings. On the report, drawn up by Bell, was founded the Scottish Judicature Act (1825), prepared by him, which effected many important changes in the forms of process in the superior courts of Scotland; the jury court being abolished as a separate judicature, and conjoined with the Court of Session. Appointed in 1832 one of the clerks of the Court of Session, he was in 1833 chairman of the Royal Commission to examine into the state of the law in general. He also prepared a bill for the establishment of a Court of Bankruptcy in Scotland. A Whig in politics, he was intimate with Lord Jeffrey; he was genial and courteous in manner, and possessed considerable culture. He died 23d September 1843. His principal works are: *A Treatise on the Laws of Bankruptcy in Scotland* (1804), and *Commentaries*

on the Laws of Scotland, which soon ranked with Stair's *Institutes* as a standard authority (1810); *Principles of the Law of Scotland* (1829); and *Commentaries on Statutes relative to Mercantile Bankruptcy* (1840).

Bell, HENRY, the father of steam-navigation in Europe, was born at Torphichen Mill, Linlithgow, April 7, 1767. After three years spent as a stone-mason, he was in 1783 apprenticed to his uncle, a millwright. He served under Rennie in London and other engineers, worked in a ship-building yard at Borrowstounness, and in 1790 settled in Glasgow, whence in 1807 he removed to Helensburgh, where his wife kept the principal inn, and he devoted himself to mechanical experiments. As early as 1786 he seems to have conceived the idea of applying steam to navigation; how far he had been anticipated by Fulton and others will be considered under the head of SHIPBUILDING. Anyhow, on 12th January 1812, a small vessel, 40 feet in length, called the *Comet*, built under his directions, and with an engine constructed by himself, was launched on the Clyde with success—the first on European waters. Bell died at Helensburgh, November 14, 1830.

Bell, HENRY GLASSFORD, lawyer and man of letters, was born in Glasgow, 8th November 1803. He attended Edinburgh University, studied law, passed as an advocate in 1832, and gained the acquaintance of the ruling literary spirits of that time in Edinburgh. He was appointed a sheriff-substitute of Lanarkshire in 1839; in 1867 he succeeded Sir Archibald Alison as sheriff, and acquired the reputation of being the best Scottish mercantile lawyer of his day. He founded (1828) and was for three years editor of the *Edinburgh Literary Journal*; besides publishing a vindication of Mary, Queen of Scots (1830); *Summer and Winter Hours* (1831); *My Old Portfolio* (1832); and *Romances and Minor Poems* (1866). He died 7th January 1874. See the Memoir by Stoddart (1892).

Bell, SIR ISAAC LOWTHIAN (1816-1904), was educated at Edinburgh and Pais. After being engaged in extensive chemical works, he founded, with his brothers, the great Clarence iron-smelting works on the Tees. He wrote many papers on metallurgical and chemical subjects; became F.R.S., D.C.L., and an officer of the Legion of Honour; was M.P. for Hartlepool from 1875 till 1880; and was made a baronet in 1885.

Bell, JOHN, of Antermoney, a celebrated Asiatic traveller, born in Campsie parish, Stirlingshire, in 1691, studied for the medical profession. In 1714 he went to St Petersburg, and soon after was appointed physician to an embassy from Russia to Persia. In 1719 he was sent upon another to China, through Siberia, from which he returned in 1721. Next year he accompanied an expedition to Persia, and in 1737 to Constantinople, where he settled for some years as a merchant. About 1746 he returned to Scotland, where he died at Antermoney, July 1, 1780. His *Travels* were published in 1763, and reprinted in Pinkerton's *Voyages and Travels*. Bell is said to have applied to Robertson for help in writing this work, when the latter recommended *Gulliver's Travels* as a model. Hence, perhaps, Bell's simplicity of style, long regarded as a model for travel-writing.

Bell, JOHN, an eminent surgeon, elder brother of Sir Charles, was born in Edinburgh, May 12, 1763. He studied under Black, Cullen, and Monro *secundus*; commenced in 1786 lecturing at Edinburgh on surgery and anatomy; and between 1793 and 1802 published his *Anatomy*. This was followed by a volume of anatomical drawings, illustrative of the structure of the bones, muscles, and joints, and another illustrative of the arteries.

In 1800 he published a *Memorial concerning Military Surgery*; his *System of Anatomy* (1793-95) was translated into German. Of his *Principles of Surgery* (1801-7) a new edition, by his brother, Sir Charles Bell, appeared in 1826. A long and bitter controversy with Dr Gregory as to the attendance of surgeons at the infirmary led to his exclusion from the same. A fall from his horse in 1816, and consequent ill-health, necessitated a visit to the Continent; and he died at Rome, April 15, 1820.

Bell, JOHN, an American statesman, born near Nashville, Tennessee, February 18, 1797, was admitted to the bar in 1816. He was a member of congress from 1827 to 1841, and was made Speaker in 1834, and Secretary of War in 1841. During this period he became, from an ardent Free-trader, a Protectionist and supporter of the Whigs, and favoured the reception of petitions for the abolition of slavery in the district of Columbia; afterwards (1858) he vigorously opposed the admission of Kansas as a slave state. He sat in the United States senate from 1847 to 1859, and in 1860 was nominated for the presidency by the 'Constitutional Union' party, but received only 39 electoral votes, cast by the states of Tennessee, Kentucky, and Virginia. He afterwards took no active share in politics, and died at Cumberland Ironworks, September 10, 1869.

Bell, JOHN, sculptor, was born at Hopton, Suffolk, in 1811, and exhibited at the Royal Academy as early as 1832, but first became well known by his figure of 'Dorothea' (1841). Among his subsequent works have been statues of Lord Falkland (1847) and Sir Robert Walpole (1854), for the new Houses of Parliament, the Guards' Memorial (1858) in Waterloo Place, and the America group in the Hyde Park Albert Memorial (1873), a replica of which, in terra-cotta, is at Washington. To Bell is due the fashion of carved wooden bread-trenchers. He died in March 1895.

Bell, ROBERT, a busy litterateur, born in 1800 at Cork, in 1828 came to London, and till 1841 was editor of the *Atlas* newspaper. He wrote *The History of Russia and Lives of the Poets for Lardner's Cyclopædia*, the last volumes of Southey's *Naval History* and Mackintosh's *History of England*, three five-act comedies, two novels, a *Life of Canning*, &c.; but he is best known by his annotated edition of the English poets from Chaucer to Cowper (24 vols. 1824-57). He died 12th April 1867.

Bell, THOMAS, naturalist, was born at Poole, Dorsetshire, in 1792, and in 1813 entered Guy's Hospital, where from 1817 till 1861 he held the post of dental surgeon, whilst also lecturing on comparative anatomy. In 1836 he became professor of Zoology in King's College, London. Elected in 1828 a Fellow of the Royal Society, from 1840 to 1853 he acted as its secretary, and he was also president of the Linnean Society (1853-61), and first president of the Ray Society (1844). He was author of *British Quadrupeds* (1837; 2d ed. 1874), *British Reptiles* (1839), *British Stalk-eyed Crustacea* (1853), and the article 'Reptiles' in Darwin's *Zoology of the Voyage of the Beagle*. In 1832 he commenced a *Monograph of the Testudinata*, of which only eight parts appeared. The plates were reissued in 1872 with letterpress by Dr Gray. He was associated with Professor Owen in the production of *Fossil Reptilia of London Clay* (1849). His, too, was the classic edition of White's *Selborne* (2 vols. 1878). Retiring from practice in his seventieth year, he had purchased the Wakes of Selborne from the grandnieces of Gilbert White, and there, after enjoying a hale and hearty old age, he died March 13, 1880.

Bella, STEFANO DELLA, born at Florence in 1610, and bred a goldsmith, was enormously impressed by the work of Jacques Callot, and early devoted himself to engraving, showing a like tendency to the macabre and grotesque. He spent some years in Paris, and was patronised by Richelieu. In all he executed upwards of 1000 different works—battles, sea-pieces, landscapes, animals, and historical scenes. All are characterised by freedom and delicacy. He died in 1664.

Belladonna, DWALE, or DEADLY NIGHT-SHADE (*Atropa belladonna*; *Belladonna*, Ital. 'fair lady,' see below; *atropa*, Gr. *Atropos*, one of the Fates; *dwale*, from A.S., connected with *dull*, from its stupefying effects), a plant of the natural order Solanaceæ (q.v.); a herbaceous perennial, growing up every year as a bush, from 2 to 4 feet high, with ovate entire leaves, and bell-shaped flowers of a lurid purple colour, which are fully larger than those of the common harebell, stalked and solitary in the axils of the leaves. It produces berries of the size of a middle-sized cherry, and which, when ripe, are of a shining black colour, and of a sweetish and not nauseous taste, although the whole plant has a disagreeable heavy smell. It is a native of the southern and middle parts of Europe, and is not uncommon in Britain, in the neighbourhood of towns and of ruins, and flowers from June to November. All parts of the plant are narcotic and poisonous, and fatal consequences not unfrequently follow from the eating of its berries, which have an inviting appearance. Its roots have sometimes been mistaken for parsnips. It owes its poisonous properties to the presence of the alkaloid Atropine (q.v.), which is found in all parts of the plant. Large doses either of belladonna or atropine produce dryness of the mouth and throat, dilatation of the pupils, dimness of vision, bright redness or an

Belladonna (Atropa belladonna):
a, flower; b, fruit.

actual rash on the skin, quickening of the pulse and respiration, talkative delirium, sometimes convulsions; at a later stage complete paralysis, stupor, and death. The treatment in cases of poisoning consists in the prompt use of emetics; and thereafter in the administration of stimulants, especially strong coffee; vegetable astringents, as tannin; and Calabar bean. In medicinal doses belladonna and atropia are used to relieve spasm, as in colic, whooping-cough; to check excessive secretions—e.g. of sweat, milk, saliva; as an antidote in poisoning by opium, Calabar bean, and prussic acid; and for many other purposes. Local application, in the form of liniment, ointment, or plaster, is often more efficacious, especially in the relief of pain, than internal administration. *Belladonna*

has been recommended as a preventive of scarlet fever, apparently on the ground of its tendency, when administered in frequent small doses, to produce an eruption and an affection of the throat somewhat similar to those characteristic of that disease; but the evidence of its utility for this purpose is not sufficient to warrant confidence. But perhaps the most important medicinal use of belladonna, and especially its alkaloid, is in the treatment of diseases of the eye (see EYE, DISEASES OF), in many of which its action is invaluable. Its power of enlarging the pupil and giving a glistening appearance to the eyes, has long been used to enhance the female charms; hence the name. For the Common Nightshade, see NIGHTSHADE; for the Woody Nightshade, see BITTERSWEET.

Belladonna Lily (*Amaryllis belladonna*), a very beautiful and nearly or quite hardy species of *Amaryllis* (q.v.), with rose-coloured drooping flowers pencilled with crimson.

Bellaggio, an Italian village beautifully situated on the promontory that separates the two arms of the Lake of Como.

Bellaire, a city and railway terminus of Belmont county, Ohio, on the Ohio River, 5 miles below Wheeling, with manufactures of glass, nails, iron, and agricultural machines; pop. 15,000.

Bellamy, EDWARD (1850-98), American journalist and author, born at Chicopee Falls, Mass., is best known by his work *Looking Backward, 2000-1887* (1888), which was received as the author's own gospel of socialism. *The Duke of Stockbridge* and two other novels were published after his death.

Bellamy, GEORGE ANNE, an English actress, born most likely at Lisbon in 1727, was the natural daughter of a Quaker school-girl and Lord Tyrawley, by whom she was educated. Having forfeited his favour by going to live with her mother, she secured an engagement at Covent Garden in 1744, and appeared with Quin as Monimia in *The Orphan*. Mrs Bellamy's professional career was brilliant; but her extravagance and profligacy were notorious. In 1785, after many alternations of fortune, a 'free benefit' released her from the debtors' prison, and in the same year she published an 'Apology' for her life (6 vols.). She died in 1788.

Bellamy, JACOBUS, a Dutch poet, born at Flushing in 1757. The son of a Swiss baker, he was indebted for his education to a clergyman and others, who subscribed to send him to the university of Utrecht. He died 10th March 1786, having published three volumes of poetry between 1782 and 1785. Collected editions of his works have appeared at Haarlem in 1826 and 1852, but they omit the finest of all his poems, *Roosje*, a romance remarkable for its pathos.

Bell Animalcules. See VORTICELLA.

Bellarmino, ROBERT, one of the most celebrated Catholic theologians, was born at Montepulciano, near Siena, in 1542. He entered the order of Jesuits at Rome in 1560, and studied theology at Padua and Louvain. Ordained priest in 1569, he was appointed the year after to the chair of theology at Louvain; but he returned to Rome in 1576 to lecture in the Roman College on controversial theology. In 1592 he became rector of the Roman College, was made a cardinal in 1599 against his own inclination, and in 1602 Archbishop of Capua. After the death of Clement VIII., he contrived to escape promotion to the papal chair, but was induced by Pius V. (1605) to hold an important place in the Vatican, where he remained until the time of his death, which took place in the Novitiate-house of the Jesuits,

September 17, 1621. Bellarmine was the chief defender of the church in the 16th century, when its antagonists were mightiest. His ponderous learning, excellent method, and moderation gained him the praise of Bayle, who will not be suspected of any bias in favour of a Jesuit. He gave a conspicuous proof of his fearless honesty in his strenuous opposition to the Pelagian tenets of Molina, a member of his own order. His great work, *Disputationes de Controversiis Christianæ Fidei adversus hujus Temporis Hæreticos* (3 vols. Rome, 1581), is regarded by Catholics as containing the best arguments for their tenets. There can be no question of the merit of his disputations as regards erudition and dialectic dexterity; but as Gerhard, in his *Bellarminus Orthodoxæ Testis*, has shown, many of the conclusions are far from being sound or logical. Industry, clearness, and acuteness are the chief merits of Bellarmine's great work; but it is seriously lessened in value by a needless subtlety, forced conclusions, and a very defective exegesis—faults which have long been evident to enlightened Catholic writers themselves. Among his other writings the most able is the *Christianæ Doctrinæ Applicatio*, which was translated into all the European languages. His book, *De Potestate Pontificis in rebus temporalibus*, in which he maintains the supremacy of the pontiff's authority over temporal princes, was condemned as treasonable in Paris and Venice. Pope Urban VIII., at the instigation of the Jesuits, declared Bellarmine to be a 'faithful servant of God'; but his canonisation as a saint has hitherto been opposed. Complete editions of his works have been published at Venice in 1721 (5 vols.), Cologne in 1619 (7 vols.), and Paris in 1874 (12 vols.). His Life was written in Italian by the Jesuit Fuligatti (Rome, 1624); an autobiography reaching down to 1613, written in Latin and hitherto withheld by the Jesuits, was edited in 1887, with a German translation, by Dollinger and Reusch. This interesting book somewhat belittles the man, if not the controversialist and theologian. There is also a Life by Couderc (Paris, 1893).

Bellary, the chief town of Bellary district, 305 miles NW. of Madras by rail. One of the principal military stations in the presidency of Madras, it is strongly defended by two lines of fortifications. The upper fort, crowning a rock 2 miles in circuit, and 450 feet high, is supplied with water from tanks excavated in the solid granite. Besides the fort and adjacent cantonments, Bellary comprises a native town to the southward, with fine military bazaars. On the north are the public offices, churches, dispensary, school, and railway station. The heat is great, but the town is considered healthy. The cotton traffic and trade of the town has been stimulated by railway connection. Pop. (1911) 58,247.—The district, lying between the Nizam's territories and Mysore, has an area of 5904 sq. m.; the population, which declined in 1871-81 owing to the famine of 1876-78, was at the census of 1911 over 1,000,000. Elevated on the east slope of the West Ghats, Bellary has an extremely dry climate. Iron, copper, lead, antimony, manganese, and alum are found; salt and saltpetre are extracted from the soil. Cotton, oil-seeds, hemp, sugar-cane, are the chief products; there are manufactures of cotton and woollen goods, and salt, chintz-stamping, and iron-smelting.

Bellay, JOACHIM DU, a distinguished French poet and prose-writer, the date of whose birth was probably 1522, though an attempt has been made to prove that it happened in 1525, 'as a compensation from nature to France for the battle of Pavia.' He was, next to Ronsard, the most important member

of the famous group of writers known as the *Pléiade*, through whom the enthusiasm and culture of the Renaissance were turned into the channel of French poetry. His *Défence et Illustration de la Langue Française* (1549), in which the aims of the *Pléiade* were explained and vindicated, marks an epoch in French literature. In this work Du Bellay maintained that French prose should be modelled as closely as might be on the Greek and Latin masterpieces; that the earlier French poetry should be set aside as trivial and shapeless; that French verse-writers should thenceforth seek to reproduce the classic stateliness of rhythm and diction in new metrical forms, such as the ode and the sonnet, adopted from their Latin and Italian predecessors. The book contributed greatly to the success of the literary revolution which was effected by the *Pléiade* (see *PLÉIADES*). In 1549 Du Bellay published a collection of sonnets which led to a brief quarrel with Ronsard on the question of priority in a new field of poetry. He was in Rome (1553-57) as secretary to his relative, the Cardinal du Bellay; but a diplomatic career did not suit him, and he had lost the cardinal's favour and fallen into difficulties before his death in 1560. His poems—nearly all translations—include a series of sonnets addressed to one Mademoiselle de Viole: *Regrets*, *Jeux Rustiques*, and *Les Antiquités de Rome*, translated by Spenser under the title of the *Ruins of Rome*. His verses give singularly graceful expression to the mood, at once pensive and pleasure-loving, which is a characteristic of most writers of the French Renaissance. A few of his poems—among them his best-known piece, the charming *Vanneur*—were admirably translated by Andrew Lang. See Marty-Laveaux's edition (1866-67), and Chamard's (1908); Life by Chamard (1900); and Paton's *Studies in the Renaissance*.

Bell-bird (*Chasmophrychus*), one of the chattering (Cotingidae), found in some of the warm parts of South America, remarkable for the metallic resonance of its cry, which resembles the tolling of a bell, with pauses varying from a minute to several minutes. It is about the size of a jay; the beak is very broad, flat, and wide in its gape; the neck and cheeks are naked. The male is of snow-white plumage, and from his forehead rises a spiral tubular appendage nearly five inches in length when fully extended. It is not the case that the wattle, or caruncle, can be erected or inflated. When extended it droops over the bill; otherwise it lies along the bill, and shrinks to half an inch in length. It becomes elongated when the bird is about to utter its characteristic note. The exact anatomical relations of the excrescence, which consists of fine elastic tissues, are not known. The bird generally takes his place on the top of a lofty tree, and his tolling, heard at a distance of three miles, resounds through the forest, not only at morning and evening, but even at midday. The female is smaller, and brightly coloured. Four species are known. In Australia and New Zealand two or more species of honey-suckers are called Bell-bird.

Belle-Alliance, the name given by the Prussians to the battle of Waterloo (q.v.), from a farm occupied by the centre of the French army.

Belle de Nuit (Fr., 'beauty of the night'), a name sometimes given to the Marvel of Peru (*Mirabilis jalapa*), sometimes also to certain tropical American and West Indian species of Convolvulaceæ, with extremely beautiful and fragrant flowers, which open only during the night.

Belleek, a village of Ireland, in the County Fermanagh, on the river Erne, below Lough Erne, is famous for the fine porcelain with pearly iridescent glaze (Belleek ware), and pottery manufactures from its own clay.

Belle Isle, a rocky island in the Atlantic, about midway between the NW. of Newfoundland and the E. of Labrador. About 21 miles in circumference, it gives name to the adjacent strait on the south-west, which, with a length of 70 miles and a greatest breadth of 11 miles, separates Labrador from Newfoundland, and forms the most northerly of the three channels between the Gulf of St Lawrence and the open ocean.—Another Belle Isle (South) lies E. of the N. projection of Newfoundland; and a third, with extensive iron mines, in the Bay of Conception, Newfoundland.

Belleisle, CHARLES LOUIS AUGUSTE FOUQUET, DUC DE, marshal of France, born in 1684 at Villfranche, in Aveyron, was the grandson of the intendant Fouquet. He early distinguished himself in the wars in Italy and the Low Countries against Spain, and afterwards in Poland. In the war of the Austrian succession, he stormed Prague in 1741, and in the following year conducted the marvellously skilful retreat to Eger. In 1757 he was made war minister, and as such introduced important improvements in the French service, reforming the promotion and camp-discipline, and increasing the military schools. He died January 26, 1761, the last of his house.

Belleisle. See FOUQUET (NICOLAS).

Belleisle-en-Mer, a French island in the Atlantic, 8 miles S. of Quiberon Point, in the department of Morbihan, measures 11 miles by 7, and has an area of 330 sq. m. The inhabitants are chiefly engaged in fishing. Salt is made along the shores, and good pastures are found in the interior. The chief town is Le Palais, a seaport and fortified place. In the 16th century, the monks of Quimperlé ceded it to Charles IX., who gave it to the Marshal de Retz, that he might fortify it. His successor sold the island in 1658 to Fouquet, intendant of finance, who further improved and strengthened it. His grandson, the celebrated Marshal Belleisle, ceded the island to Louis XV. in exchange for the Comté Gisors (1718). It was captured in 1761 by the English fleet under Keppel, but restored in 1763.

Bellenden (BALLANTYNE), JOHN, of Moray, a Scottish writer in the reigns of James V. and Queen Mary, was born towards the close of the 15th century, and in 1508 matriculated at St Andrews as 'of the Lothian nation.' He completed his education at Paris, where he took the degree of D.D. at the Sorbonne. Bellenden is best remembered by his translation of Boece's *Historia gentis Scotorum*, and of the first five books of Livy (both done in 1533), interesting as specimens of the Scottish prose of that period, and remarkable for the ease and vigour of their style. To each of these works are prefixed metrical *prohemies* or prologues. Bellenden's *Croniklis of Scotland* professes to be a translation of Boece, but it is a very free one, and contains numerous passages not to be found in the original, so that it is in some respects to be considered almost an original work. The author enjoyed great favour for a long time at the court of James, at whose request he executed the translations. As the reward of his performances, he received grants of considerable value from the treasury, and afterwards was made archdeacon of Moray and canon of Ross. Becoming involved, however, in ecclesiastical controversy, he left his country, and, according to Bale and Dempster, went to Rome, where he died about 1550, or as late as 1587. The Livy was first published in 1822 by Thomas Maitland (Lord Dundrennan), uniform with his edition of the *Croniklis* (1821); and by W. A. Craigie (S.T.S. 1901-3).

Bellenden, WILLIAM, a Scottish author, who was born, it would seem, at Lasswade, about 1555,

and who died about 1633. Most likely a Catholic, he was a professor in the university, and an advocate in the parliament, of Paris, and was employed there in a diplomatic capacity by James VI., who about 1610 conferred on him the appointment of Master of Requests (*magister libellorum supplicum*). His *Ciceronis Princeps* (1608), *Ciceronis Consul, Senator, Populusque Romanus* (1612), and *De Statu Prisci Orbis* (1615), he republished in 1616 under the title *De Statu Libri tres*. His crowning labour was *De Tribus Luminibus Romanorum* (1634), the 'three luminaries' being Cicero, Seneca, and Pliny, out of whose works he intended to compile, on the same plan as his previous works, a comprehensive digest of the civil and religious history, and the moral and physical science, of the Romans. 'Bellenden,' says Hallam, 'seems to have taken a more comprehensive view of history, and to have reflected more philosophically on it, than perhaps any one had done before.' His works furnished the materials for Middleton's *Life of Cicero*. Warton first denounced the theft, which was afterwards made clear by Dr Parr in his edition of the *De Statu* (1787).

Bellerophon (originally called HIPPOPHON) was the son of the Corinthian king Glaucus, and Eurymede, daughter of Sisyphus. Other accounts make Neptune his father. Having accidentally killed the Corinthian Bellerus, he fled to his relative Protus, king of Argos, whose wife, Antea, fell in love with the young hero. He rejected her offers, whereupon in revenge she poisoned her husband's mind against his guest. Protus sent him to his father-in-law, Iobates, king of Lycia, with a sealed message, asking Iobates to cause the youth to be slain. The latter, reluctant to do so directly, imposed upon Bellerophon the seemingly impossible task of slaying the formidable Chimæra (q.v.). Mounted on the winged steed Pegasus (given to him by Pallas), the hero ascended into the air, and succeeded in slaying the monster with his arrows. He was next sent against the Amazons, whom he also defeated. On his way home he destroyed an ambuscade of Lycians, set by Iobates for his destruction. That monarch now thought it useless to attempt his death, and, as a sort of recompense, gave the hero in marriage his daughter Philonoe, by whom he had three children—Isander, Hippolochus, and Laodameia. Homer relates that he at last drew on himself the hatred of the gods, and wandered lonely through the Aleian field. Pindar relates that Bellerophon on Pegasus endeavoured to mount to Olympus, when the steed, maddened by Jove through the agency of a gadfly, threw his rider, who was stricken with blindness. Bellerophon was a favourite subject in ancient art. His story was dramatised by Sophocles in *Iobates*, and by Euripides in *Sthenoboa* and *Bellerophontes*, but not one of the three has come down to us.

Bellerophon, an extinct genus of molluscs, known as an abundant fossil. The shell is spirally coiled in one plane, and the outer margin has a deep notch. About 300 species are known, persisting from the Cambrian to the Carboniferous

Bellerophon tangentialis.

strata. Bellerophon has been bandied about from one division of molluscs to another. Montfort, who established the genus, placed it among cepha-

lopods; till lately it was regarded as a heteropod; now it is placed among fissobranch gasteropods, not far from the common ear-shell, and nearer the family Pleurotomariidae.

Belles-lettres, a term adopted from the French into the English and various other languages. It is commonly used in a somewhat general sense to designate the more elegant or refined departments of literature. In English usage it is synonymous with another vague expression, *polite literature*, including history, poetry and the drama, fiction, essays, and criticism.

Belleville, an eastern suburb or outlying section of Paris, was enclosed by the line of fortifications. It is largely inhabited by the poorest class of workmen, and is notable as a centre of Communistic agitation.

Belleville, a thriving city in the province of Ontario, Canada, situated on the Bay of Quinte, Lake Ontario, 48 miles W. of Kingston by rail. It is the seat of Albert University (1857). Pop. 12,000.

Belleville, a city of Illinois, U.S.A., situated in a productive region, 16 miles S.E. of St Louis, with coal-beds in the vicinity, and manufactures of iron goods, thrashing-machines, glass, shoes, beer, flour; pop. 25,000, largely German.

Belley, a town in the French department of Ain, 40 miles E. of Lyons. It has a cathedral dating from 889, and fine lithographing stones are procured in the neighbourhood. Pop. 7000.

Belligerent. See ENEMY, NEUTRALITY.

Bellingham, a city and seaport of Whatcom county, Washington, has timber and salmon-canning industries; pop. 26,000.

Bellingham. See PERCEVAL.

Belli'ni, the name of a Venetian family which produced several remarkable painters. The earliest was JACOPO BELLINI, who died in 1470. He was a pupil of the celebrated Gentile da Fabriano, and was the first to bring to Venice the skill of Florence. Most of his pictures have perished.—His elder son, GENTILE BELLINI (born probably in 1424; died 1507), was distinguished as a portrait-painter, and also for his professional groups, with fine architectural perspective. Along with his brother, he was commissioned to decorate the council-chamber of the Venetian senate. Mohammed II., having by accident seen some of his works, invited Gentile to Constantinople, employed him to execute various historical works, and dismissed him laden with presents. The 'Preaching of St Mark' is his most famous achievement.—His more celebrated brother, GIOVANNI BELLINI (born about 1428; died 1516), was the founder of the older Venetian school of painting, and contributed greatly to its progress. His works are marked at first by a somewhat hard manner and severe drawing, due to the influence of his brother-in-law, Andrea Mantegna, but gradually increase in warmth and tenderness to the very last. His best works are altar-pieces and devotional pictures, and these rank among the noblest products of the religious art of the world. Among his numerous pupils the most distinguished were Giorgione and Titian.

Belli'ni, VINCENZO (1802-35), operatic composer, was born at Catania, in Sicily. An organist's son, he was sent by a Sicilian nobleman to the Conservatorio of Naples, and there was instructed in composition by Tritto and Zingarelli. His opera, *Il Pirata*, immediately carried his name beyond Italy, and for the short remainder of his life fresh operas appeared almost every year, and were received with unstinted applause. Worthy of mention are *I Capuleti ed i Montecchi* (1830); *La Sonnambula* (1831); and *Norma* (1832), his best and most popular work. In 1833 he went to

Paris, where he became acquainted with music other than Italian. He was received with great applause in London, whither he had accompanied the famous Pasta, for whom he had written *La Sonnambula*. After his return to Paris, he wrote *I Puritani* (1834), which shows the influence of the French school, but without seville imitation. Bellini was the most genial and original of all the followers of Rossini. His compositions are entirely devoid of either dramatic vigour or musical depth, but, even in their sometimes monotonous melancholy, display irresistible sweetness. See books by Pougin (1868) and Lloyd (1909).

Bellinzo'na, or BELLENZ, the chief town of the Swiss canton of Ticino, on the left bank of the river Ticino, 109 miles SSE. of Lucerne by rail. It has still its three old castles, which, with their towers and battlements, give the place a medieval appearance. Pop. 10,000, mostly Italian-speaking.

Bellman, KARL MICHAEL (1740-95), 'the Swedish Anacreon,' born at Stockholm, held a series of government sinecure posts there. See SWEDEN (*Literature*).

Bell-metal. See BELL.

Belloc, HILAIRE, born near Paris, 27th July 1870, of French and English parentage, was educated at Edgbaston Oratory School and (after service in the French artillery) at Balliol. Naturalised in 1903, he sat in parliament as a Liberal (1906-10), for South Salford, and became well known as journalist, poet (serious and humorous), essayist, topographer, novelist, satirist, politician, military historian, and Roman Catholic, among other capacities.—His sister MARIE ADELAIDE BELLOC-LOWNDES is a novelist.

Bello Horizonte, capital of the Brazilian state of Minas Geraes, 60 miles NW. of the old capital Ouro Preto, is an attractive modern town, built since 1894; pop. 40,000.

Bello'na, the goddess of war among the Romans, probably a Sabine divinity, was described by the poets as the companion, sister, or wife of Mars, and was represented as armed with a bloody scourge, and as inspiring her votaries with a resistless enthusiasm in battle. During the war with the Samnites, 296 B.C., the consul Appius Claudius vowed a temple to Bellona, which was erected afterwards in the Campus Martius. In this temple the senate gave audience to embassies from foreign powers, and also to returning consuls, whose claims to a triumph and entrance into the city would have been nullified. The priests of the goddess were styled *Bellonarii*, and at their mystic festivals, especially on the 'day of blood' (March 20), used to gash their own arms and shoulders, and thus to offer their blood.

Bellet, JOSEPH RENÉ, Arctic explorer, was born in Paris, 18th March 1826. A lieutenant in the French navy, he served with distinction in the French expedition against Tamatave in 1845, and in May 1851 he joined the expedition in search of Sir John Franklin, sent out by Lady Franklin. Distinguished by his noble daring and spirit of enterprise, he took part in several explorations; in one of which he discovered Bellet Strait. He was lost in an ice crack in Inglefield's expedition, 21st August 1853. His *Journal* was edited by Lemer at Paris in 1854 (Eng. trans. 1855).

Bellet Strait, the passage on the north coast of North America which separates North Somerset from Boothia Felix, and connects Prince Regent Inlet with Franklin Channel. Its east entrance was discovered in 1852 by Lieutenant Bellet. After four unsuccessful attempts, it was explored for the first time by M'Clintock on his crowning voyage. It is about 20 miles long, and, at its

narrowest part, about 1 mile wide, running pretty nearly on the parallel of 72°, between granite shores which, everywhere high, rise here and there to 1500 or 1600 feet. Through this funnel both the winds and the waters have full play; the latter, permanent currents and flood-tides alike, coming from the west. A point on the south shore, 71° 55' N., 95° W., is the most northerly point of the North American continent.

Bellows. See BLOWING MACHINES.

Belloy, PIERRE LAURENT BUIRETTE DE, one of the first French dramatists who ventured to introduce on the stage native instead of classical heroes. He was born at St Flour, in Auvergne, in 1727, and educated for the law; but the seductions of the stage proved irresistible, and under the name of Dormont he played for some years at St Petersburg and other northern cities. In 1758 he returned to France to superintend the bringing out of his tragedy *Titus*, trusting that its success would reconcile his family to him. In this, however, he was disappointed, for the piece proved a failure, being only a feeble imitation of Metastasio, and he returned to St Petersburg. In 1762 he again visited France, and obtained a decided success by his tragedy of *Zelmire*. It was followed by *Le Siège de Calais* (1765), *Gaston* et *Bayard* (1771), and *Pierre le Cruel* (1772). He died at Paris, 5th March 1775. His collected works were edited by Gaillard in 6 vols. in 1779; a selection by Anger in 2 vols. appeared in 1811.

Bell Rock, or INCHCAPE, a reef of old red sandstone rocks in the German Ocean, 12 miles SE. of Arbroath, and nearly opposite the mouth of the Tay. The reef is 2000 feet long; at high water of spring-tides it is covered to a depth of 16 feet, at low water is partly uncovered to a height of 4 feet; and for 100 yards around, the sea is only 3 fathoms deep. It was formerly a fruitful cause of shipwreck, and, according to tradition, the abbot of Aberbrothock (Arbroath) placed a bell on it, 'fixed upon a tree or timber, which rang continually, being moved by the sea, giving notice to the saylers of the danger.' This tradition has been embodied by Southey in his well-known ballad of *The Inchcape Rock*. A lighthouse, 120 feet high, designed by Robert Stevenson and Rennie, was erected in 1807-10, at a cost of £61,331. A new lightroom was built in 1902.

Section of Bell Rock Lighthouse.

Bellu'no (the ancient *Bellunum*), a cathedral city of Venetia, Northern Italy, finely situated on the right bank of the Piave, 42 miles N. of Treviso. It is the capital of a province. Pop. 20,000.

Beloit, a city of Wisconsin, U.S.A., on Rock River, 75 miles SW. of Milwaukee by rail. It has a college (1847), several flour and paper mills, foundries, and manufactories of agricultural implements, &c. Pop. 21,000.

Belon, PIERRE, a French naturalist, born in 1518 at Soulethière in Maine, studied medicine at Paris, and in 1546 set out on a journey to Greece, Asia Minor, Egypt, and Arabia. He returned in 1549, and in 1553 published the results of his travels. In April 1564 he was murdered by robbers whilst gathering herbs at a late hour of the evening.

in the Bois de Boulogne. Besides his book of travels, Belon wrote several valuable treatises on trees, herbs, birds, and fishes. He was one of the first who established the homologies between the skeletons of different vertebrates; he planted the first cedar in France; and he formed two botanical gardens more than a century before the creation of the Jardin des Plantes. A statue of him was unveiled at Le Mans in October 1887.

Belone. See GAR-PIKE.

Belper, an urban district of Derbyshire, on the Derwent, $7\frac{1}{2}$ miles N. of Derby. It owes its prosperity to the cotton-works of Messrs Strutt, one of whom was in 1856 created Lord Belper. The manufacture of cotton yarn and cotton hosiery is largely carried on; and there are ironworks and engineering-shops. Pop. 12,000.

Belsham, THOMAS, a Unitarian theologian, was born at Bedford, 26th April 1750. The son of a dissenting minister and of a granddaughter of the first Earl of Anglesey, he was educated a Calvinist, and became pastor of an Independent congregation at Worcester in 1778, and head of the theological academy at Daventry in 1781. These offices he resigned in 1789, on embracing Unitarian views, and shortly after received the charge of a new theological academy at Hackney, which collapsed for want of funds in 1796. Before its extinction he succeeded Priestley in his pastoral charge of the Gravel-pit Unitarian Chapel, Hackney, and from 1805 till his death, 11th November 1829, filled the pulpit of Essex Street Chapel. Most of his numerous works are controversial. His doctrine regarding the person of Christ represents the purely 'humanitarian' view, as distinguished from the more nearly Arian sentiments of men like Channing. He published also *Elements of the Philosophy of the Human Mind* (1801); a memoir of his predecessor, Theophilus Lindsey (1812; centenary edition, 1873); *The Improved Version of the New Testament* (1808); and the *Epistles of Paul translated* (4 vols. 1822). See his Life by Williams (1833).—His brother, WILLIAM (1752–1827), was an active and voluminous writer of history and political tracts on the side of the Whigs. His principal work, written in a liberal spirit, and in a clear and simple style, was his *History of Great Britain to the Conclusion of the Peace of Amiens* (12 vols. 1806).

Belshazzar, the name of a Babylonian prince mentioned in the book of Daniel as the last Chaldean king of Babylon, slain at the capture of the city by the Medes and Persians. No ancient historian mentions his name as one of the successors of Nebuchadnezzar, but the Babylonian cuneiform inscriptions give the name Bel-sar-uzar as that of the son of Nabonidus, the last king of Babylon (555–538 B.C.), and one of his later inscriptions gives ground for the inference that the son was associated with his father on the throne. According to the book of Daniel he had a divine intimation of his impending fate in the words written by an invisible hand upon the wall, *Mene, Mene, Tekel, Upharsin* (lit. 'numbered, numbered, weighed, and divisions').

Belt, the name given to two straits, the GREAT and the LITTLE BELT, which, with the Sound, connect the Baltic with the Cattegat. The GREAT BELT, nearly 40 miles in length, and varying in breadth from about 10 to nearly 20 miles, divides the Danish islands, Zealand and Laaland, from Fünen and Langeland. The LITTLE BELT divides the island of Fünen from Jutland. It is equal in length to the Great Belt, but much narrower. Its greatest breadth is about 10 miles, but it gradually narrows towards the north, until at the fort of Fredericia it is less than a mile wide; thus the

passage from the Cattegat into the Baltic is here easily commanded. Both the Belts are dangerous to navigation on account of numerous sand-banks and strong currents; and therefore, for large vessels, the passage by the Sound (q.v.) is preferred.

Bel'tane, BELTEIN, or BEALTAINN, the name of a heathen festival once common to all the Celtic nations, and traces of which have survived to the present day. The name is derived from *tin* or *terne*, fire, and *beal*; *Beal* is understood to be the name of a god not directly connected with the Asiatic Belus, but a deity of light peculiar to the Celts, appearing as Belinus in Ausonius, Tertullian, and numerous inscriptions. The great festival of this worship among the Celtic nations was held in the beginning of May, but there seems to have been a somewhat similar observance in the beginning of November—the beginning and the end of summer. On such occasions, all the fires in the district were extinguished; the *needfire* was then kindled with great solemnity, and from this sacrificial fire the domestic hearths were rekindled.

The earliest mention of the beltane is found in Cormac, Archbishop of Cashel in the beginning of the 10th century. Two fires were lighted side by side, and to pass unhurt between them was wholesome for men and cattle. Traces of this usage existed in the Scottish Highlands even in the 19th century, and it is more than probable that the leaping through the flames which was then practised was a survival of a time when sacrifices of animals and even of human beings were thus offered. At Carnac, in Brittany, and in the Irish South Isles of Aran to the present day, the domestic animals are driven through the flames, and thus obtain immunity from accident and disease throughout the year.

Some scholars have striven to identify the worship of the Celtic Beal with that of the Baal or Bel of the Phœnicians and other Semitic nations. It is unnecessary, however, to go beyond the family of nations to which the Celts belong in order to find analogies either for the name or the thing. Grimm identifies the Celtic Beal not only with the Slavonic *Belbog* or *Bjelbog* (*bel* or *bjel*, 'white,' *bog*, 'a god'), but also with the Scandinavian and Teutonic Balder or Paltar, whose name appears under the form of *Baldag* ('the white or bright day'), and who appears to have been also extensively worshipped under the name of *Phol* or *Pol*. The universality all over Europe in heathen times of the worship of these personifications of the sun and of light through the kindling of fires and other rites, still finds a survival in the periodical lighting of *bonfires*. The more marked turning-points of the seasons would naturally determine the times of these festivals. The two solstices at midwinter and midsummer, and the beginning and end of summer, would be among the chief seasons. The periods of observance, which varied, no doubt, originally, more or less in different places, were still further disturbed by the introduction of Christianity. Unable to extirpate these rites, the church sought to Christianise them by associating them with rites of her own, and for this purpose either appointed a church-festival at the time of the heathen one, or endeavoured to shift the time of the heathen observance to that of an already fixed church-festival. All over the south of Germany, the great bonfire celebration was held at midsummer (*Johannisfeuer*), a relic, probably, of the sun-festival of the summer solstice: throughout the north of Germany, it was held at Easter. It is probable that this fire-festival (*Osterfeuer*) of Ostara—a principal goddess (Eastre) of the English—had been originally held on the 1st of

May, and was shifted so as to coincide with the church-festival now known as Easter.

In Great Britain, St John's Eve was celebrated with bonfires; and Easter had its fire-rites, which, although incorporated in the service of the Roman Catholic Church, were clearly of heathen origin. But the great day for bonfires in the British Islands was the 1st of November. Fewer traces of this are found in other countries, and therefore we must look upon it as more peculiarly Celtic.

Belts and Belting. The term belt is employed to indicate the flexible connecting piece which, by means of its frictional resistance to slipping, enables a revolving pulley to give a rotational motion to another pulley. These flexible belts are usually made from leather, which has been tanned by oak bark, or some other suitable bark such as that of American hemlock spruce, wattle, &c. Pure vulcanised india-rubber, or india-rubber with interposed plies of canvas, and waterproofed woven cotton belts are also largely used, especially in situations where leather belting would be unsuitable; in fact, most of the well-known textile fibres have been employed to manufacture belting. In general, belts are flat strips running on pulleys with flat or slightly rounded rims; sometimes grooves are formed in the pulley-rims, and then the belts are circular in cross-section, or else ordinary hemp or wire ropes are employed. The belt is made into an endless band by means of a laced joint, or by the use of special metal fasteners, usually so made that the joint may be easily broken when it is necessary to tighten the belt at any time. If the endless band is used as an open belt, the two pulleys will rotate in the same direction; whereas if the band is used as a crossed belt, the two pulleys will revolve in opposite directions.

The most essential qualities in a belt are (1) good grip of the surface of the pulley-rim; (2) strength to resist the tension in the belt, which is requisite in order to transmit power from one pulley to the other; (3) non-liability to stretch; (4) durability. The coefficient of friction for leather belting running on iron pulleys when the belting is new varies from 0.3 to 0.4, but when the belt has been in use for some time, and has become a little greasy, the coefficient has a lower value. If the belt is in contact with one-half the circumference of the pulley, then the ratio of the tension in the belt on the tight or driving side to that on the slack side for a coefficient of friction 0.22 is very nearly 2, and for a coefficient of friction equal to 0.3 it is 2½.

The working tension for ordinary leather belting should not exceed 330 lb. per square inch of section; the thickness of single belting varies from $\frac{3}{8}$ to $\frac{3}{4}$ inch; hence the working tension in such belts should not exceed about 65 lb. per inch width of belt. In order to prevent excessive wear from the belt slipping on the pulley-rim, the smallest pulley diameter should not be less than about thirty-five times the thickness of the belt, which means a 7-inch pulley for a single belt, and about 21 inches diameter for a treble belt. In ordinary working the total slip should not exceed about 2 per cent. of the belt velocity; when the slipping becomes excessive, the belt is liable to be thrown off the pulley. When belts are driven at speeds of less than 2000 feet per minute, the effect of centrifugal force is negligible; but when speeds are increased to 6000 or 7000 feet per minute, centrifugal force becomes an important factor, and must be taken into account in calculating the amount of power a belt will transmit.

Cotton belting is cheaper and stronger than leather belting, and can be obtained in widths varying from 1½ inch to 60 inches, and with

varying numbers of plies. The strength of 8-ply is said to be over 1100 lb. per inch of width.

Leather chain belting is formed of short pieces or links of leather joined together by metal rivets. This belting is more flexible than ordinary leather belting, it can be easily shortened when necessary, and is very suitable for driving dynamos for electric lighting and similar purposes; it can be obtained up to 33 inches in width (see Unwin, *Elements of Machine Design*, part i.; *Trans. Am. Soc. Mech. Eng.*, vii. 347, 540; xv. 204). Flat belting is now extensively used for transporting such materials as grain in flour-mills, &c.

Belu'chistán, or BALUCHISTAN, a country of southern Asia, bounded on the N. by Afghanistan, on the E. by Sind, on the S. by the Arabian Sea, and on the W. by the Persian province of Kerman. It has a coast-line of over 500 miles, and corresponds in general with the ancient Gedrosia, save that the latter extended to the Indus. The area is 135,000 sq. m. The population enumerated in 1921 was 800,678; but in addition there are probably about 1,000,000 nomads. Anciently a part of Persia, it is now a province of the Indian Empire. In bygone ages the Beluchi Desert formed a barrier for the Lower Indus, constraining every assailant from Alexander downwards to prefer the less barren, though perhaps more rugged, route through Afghanistan into the Punjab—a preference strengthened by Alexander's direful experience in returning from the Indus along the coast. Until 1810 Beluchistan was almost entirely a *terra incognita* to Europeans. Most of the country, indeed, is still little known, but railway surveys established its general features. A railway entering from Sind runs by Quetta and by Harnai to the Afghan frontier; and from it a line runs by Nushki into Persia. The surface is generally mountainous, more especially towards the north, where branches of the great Suliman Range, running north and south, rise to a height of 12,000 feet. The ranges in the south generally run east and west, parallel with the coast, and the longitudinal valleys between form the principal thoroughfares, there being no regular routes in the country except those through the Bolan and Mula passes to Quetta and Kalát. Even the bottoms of some of the valleys have an elevation of 5700 feet; and the capital of the chief state, Kalát, or Kelát, on the side of one of them, is 6783 feet above sea-level. Large deserts, rendered impassable in summer by sandstorms, and swept in winter by benumbing, piercing winds, occupy hundreds of square miles of the country; and the rivers—unless after heavy rains, when those in the north-east frequently inundate great tracts of country—are inconsiderable, few of the streams in the south appearing to be perennial at all. The west is largely a land of drought, with stretches of sand varied by bare hills and treeless valleys. The temperature is one of striking and sudden extremes, 125° F. in the shade having been registered on the coast even in March, although at Kalát in February water has been observed to freeze as it was poured on the ground. The pastures, as may be supposed, are poor, so that there are few cattle; sheep, however, as well as mountain goats and antelopes, are numerous. The camel is the ordinary beast of burden; but in the north-west, towards Kerman, serviceable horses, with a marked strain of Arab blood, are bred. The wild animals include the tiger, leopard, wolf, hyæna, ape, wild ass, &c.; and fish in great quantities are caught off the coast. Wherever there is a sufficiency of water the soil is productive—the lowlands yielding rice, sugar, cotton, indigo, and tobacco; and the higher grounds, wheat, barley, madder, maize, and pulse. The mountains are bare at the top, and their slopes are scantily

wooded as a rule; but in the valleys the almond, olive, and peach grow wild, and even the deserts furnish a useful brushwood. The gardens produce excellent fruits of all sorts, and in the sandy coast-district of Mekran, or Makran, the date is carefully cultivated. The minerals are gold, silver, copper, lead, antimony, iron, tin, sulphur, alum, sal-ammoniac, chromite, salt, and petroleum; the manufactures are chiefly carpets, tent-covers of goat's and camel's hair, and rude firearms. The capital of Kalát is Kalát (q.v.), with about 2000 inhabitants, an old citadel, and a number of badly built and very dirty houses. Mastung (population, 5000) is the most thriving township in the state. There are no seaports, the fishing-villages in the south being mere collections of wretched hovels; but along the surf-beaten, sandy cliffs of the coast some sheltered roadsteads are found. The best of these are Sonmiani Bay, Homara, and Gwadar, the last having a fort and a telegraph station. There is an insignificant inland trade, chiefly in the hands of Hindus.

The inhabitants belong to the distinct races of Brahui and Beluchis. The Brahui, who are hospitable and generous, are the aboriginal, dominant, and most numerous race—it has even been proposed to call the country Brahuistan. The Beluchis, praised by some travellers and dispraised by others, are powerful on the borders. Opinions have been widely divided as to the origin of the Brahui, many assuming their kinship with the Dravidians of southern India, although apparently on insufficient grounds. Their language is classed as Dravidian, but appears to contain many ancient Hindu words, and echoes the accent of the Punjab dialect. In appearance they are short, sturdy, and strongly built, with round, flat faces, and brown hair. Their dress is a coarse calico tunic, with trousers fastened at the ankles, and a skull-cap with sash of the same colour. The Beluchis are of Iranian descent, with a mingling of Tatar blood, and their language closely resembles modern Persian; they are both a numerically smaller and a more recent element than the Brahui. They are tall, with longer and more prominent features, and are brave, but restless and prone to predatory warfare, in which they frequently show themselves senselessly cruel. Their dress is distinguished from that of the ruling race by a turban and wider trousers not confined at the ankles. The women's attire is very much the same as the men's. Both races are inured to extremes of heat and cold, and are capable of considerable exertion; but the normal life of the Beluchis, at least, is one of laziness and indulgence, broken only by hunting, racing, and athletic contests. Both are Mohammedans of the Sunni sect, but the teaching of the Koran is confused with numberless superstitious beliefs. Besides these two races, there are colonies of Persian descent called Delhwars, who form a vassal class, Lasis, Khetians, Jats, indigenous Hindus, servile Ghulams, and Afghans.

The Indian province of Beluchistan includes (1) British Beluchistan (9000 sq. m.), constituted in 1887 out of certain districts (Shorarud, Duki, Sibi, and Shahrig) ceded by Afghanistan in 1879; (2) Agency Territories (including among others Quetta, the Bolan Pass, and tribal areas) leased from the khan of Kalát or otherwise brought under British administration (45,000 sq. m.); (3) the states of Kalát and Las Bela (80,000 sq. m.). The province is under a high commissioner. The capital is Quetta (q.v.).

Beluchistan is, in a somewhat indefinite manner, under the authority of the khan of Kalát. The khan having acted treacherously towards the British during the Afghan campaign of 1839, his royal city was taken by storm. In 1841 it was

again captured, for temporary occupation, by the British. In 1877 England obtained by treaty with the khan the right of permanently occupying Quetta (which was annexed, with his consent, in 1887), and of having a political agent at Kalát; and the khan practically became a feudatory of the Indian Empire, and placed his territory at the disposal of the British government for all military and strategical purposes, gaining by its moral support a prestige that has made his authority more respected by the semi-independent chiefs of the pastoral tribes. In 1893 the reigning khan was deposed by the British, and his son peacefully proclaimed in his stead. The khan of Kalát rules some 72,000 sq. m., and a population of 470,000; the jam of Las Bela 7100 sq. m., and 61,000.

PERSIAN BELUCHISTAN is that part of south-eastern Persia which adjoins Indian Beluchistan. It is included in the province of Kerman. There are Beluchis not only in India and Persia, but also in Oman.

See Bellew's *From the Indus to the Tigris* (Lond. 1874); works on Beluchistan by Hughes (1877), Macgregor (1882), Floyer (1882), and Olver (1890); Thorntun, *Life of Sandeman* (1895); Holdich, *The Indian Borderland* (1901), and *The Gates of India* (1910); M. L. Dames, *The Baluch Race* (1904), and *Popular Poetry of the Baluches* (1907).

Beluga, or WHITE WHALE (*Beluga* or *Delphinapterus leucas*), one of the dolphin family, closely related to the narwhal. The body is from 12 to 16 feet in length, of graceful proportions, and remarkable for its creamy-white colour, and for the absence of a dorsal fin, which is represented only by a slight ridge. The flippers are short; the head is arched, and sinks abruptly to the short rounded snout; the teeth are small and conical, comparatively few in number (8 to 10 on each half-jaw), somewhat distant from one another, absent posteriorly, and often falling out in the adults. It is a markedly gregarious animal, associating in droves of both sexes. The female shows great solicitude for her young. These are at first of a bluish-gray colour. The white whales feed on fishes, which they often follow far up the rivers—e.g. the St Lawrence and the Amur. According to Eschricht, they also eat cuttle-fishes. They are fearless sportive animals, and have been successfully kept in aquaria. Their headquarters are round Greenland, but they occur all over the Arctic seas, often going as far south as the St Lawrence. They only rarely appear on British coasts. The Greenlanders capture them in the fords by means of strong nets, or by harpooning, though the comparatively soft skin often fails to retain the weapon. The flesh is largely eaten, the fat yields very fine oil, the skin is made into leather, and some of the internal membranes are also utilised. This name is also applied to a great Russian sturgeon (the *Bielaga* or *Huso*). See CETACEA, DOLPHIN, NARWHAL, WHALE.

Belur', a village of Mysore, 130 miles W. of Bangalore. Known in the Purānas as *Velapura*, locally regarded as the Southern Benares, it is the site of a celebrated temple.

Belus. See BAAL.

Belvedere (It., lit. 'fine view'), a raised turret or lantern on the top of a house, or a high summer-house in a garden or park, from which to look out on the surrounding country. A part of the Vatican in Rome is known as the Belvedere, and gives its name to the famous statue of Apollo (q.v.). The picture-gallery in the palace at Vienna bears the same name. Others are at Warsaw, Prague, and Weinmar.

Belvedere (*Kochia scoparia*), an annual belonging to the Chenopodiaceæ (q.v.), a native of

the middle and south of Europe. It has long been familiar in British gardens as an ornamental annual, not upon account of its flowers—for they have no beauty—but of its close pyramidal, rigid form, and numerous narrow leaves, which give it some resemblance to a miniature cypress-tree. It is hence sometimes called Summer Cypress.

Belvoir. See MANNERS, FOXHUNTING.

Belzoni, GIOVANNI BATTISTA, a famous traveller, was born, the son of a poor barber, at Padua in 1778. He was educated at Rome for the priesthood, but soon displayed a preference for mechanical science, and when the French republican troops took possession of the pontifical city, quitted his religious studies altogether. About the year 1800 he visited Holland, and in 1803 came to England. Six feet seven inches tall, for a time he gained a living by exhibiting feats of strength, at first in the streets, and afterwards at Astley's. At the same time, however, he continued his mechanical studies, and exhibited models of hydraulic engines in the large towns of the kingdom. After a sojourn of nine years in England, he went to Spain and Portugal in his capacity of theatrical athlete. From the Peninsula he passed to Malta, and thence to Egypt in 1815, on the invitation of Mehemet Ali, who wished him to construct a hydraulic machine for the irrigation of his gardens near Cairo. Although he succeeded in this undertaking, the design was abandoned by the pasha, and Belzoni was induced by the traveller Burckhardt and Mr Salt, the British consul, to direct his attention to the exploration of Egyptian antiquities. He threw himself with ardour into his new vocation. He removed the colossal bust of the so-called 'Young Memnon' from the neighbourhood of Thebes to Alexandria, and was the first who opened the temple of Abu-Simbel. In the valley of 'the tombs of the kings'—Biban-el-Moluk—near Thebes, he discovered several important catacombs containing mummies, and among others, opened in 1817 the celebrated grotto-sepulchre of Seti I., from which he removed the splendid sarcophagus, now, along with the 'Young Memnon,' and other results of Belzoni's labours, in the British Museum. But his greatest undertaking was his opening of the second pyramid of Gizeh, supposed since Herodotus' time to contain no interior chamber. An attempt made on his life caused his departure from Egypt, but previously he made a journey along the coast of the Red Sea, and another to Lake Mœris and the Lesser Oasis, which he erroneously supposed to be that of Siwah (q.v.), in search of the ruins of the temple of Jupiter Ammon. In the course of his explorations he discovered the emerald mines of Zubara and the ruins of Berenice, the ancient commercial entrepôt between Europe and India. In 1819 he returned to Europe, and in 1821 published at London his *Narrative of Excavations in Egypt and Nubia*. In 1821 he opened in London a successful exhibition of his Egyptian antiquities, which he took to Paris in the following year. Becoming restless, he soon afterwards undertook a journey to Timbuktu, in Central Africa. At Benin he was attacked by dysentery, from which he died at Gato, December 3, 1823.

Bem, JOSEPH, a Polish leader of the Hungarian insurgents, was born in 1795 at Tarnov, in Galicia. After thirteen years' military service (1812-25), and after taking an active part in the Polish rebellion of 1830-31, he went to France, where he earned a livelihood by teaching mechanics and mnemonics. In 1848, having failed in an attempt to organise an insurrection in Vienna, he joined the Hungarians, and was intrusted with the command of the army of Transylvania, amounting to

10,000 men. He soon defeated the Austrians in several engagements, announcing his victory over the famous Ban Jellachich in the laconic despatch, *Bem Ban Bum* ('Bem has beaten the Ban'); and finally succeeded, in March 1849, in driving both them and their allies, the Russians, into Wallachia. He then proposed, by amnesties and general mild rule, to gain the adherence of the German and Slavonic population; but his propositions were not entertained by Kossuth and the Hungarian commissariat. After expelling the troops under Puchner from the Banat, Bem returned into Transylvania, where the Russians had defeated the Hungarians. Here he was defeated in a battle near Schassburg, where he was opposed to three times the number of his own troops. At Kossuth's request he now hastened into Hungary, and took part in the unfortunate battle near Temesvar. Retreating into Transylvania, he defended himself for some days against a vastly superior force, and then made his escape into Turkey, where he embraced, from political motives, the profession of Islam, and, as Amurat Pasha, obtained a command in the Turkish army. In February 1850 he was sent to Aleppo, where, after suppressing the sanguinary insurrection of the Arabs against the Christian population, he died of fever, December 10, 1850. Bem was distinguished as a general by promptness and courage, and his personal kindness made him popular with his followers.

Bembato'ka, BAY OF, a safe and commodious bay on the NW. coast of Madagascar, in 16° S. lat. and 46° E. long. The river Betsiboka, with the Ikiopa, drain into the bay; the former, which is about 300 miles long, is navigable for small steamers for about 90 miles. Majunga, on the north side of the bay, is the second port in the island, with about 7000 inhabitants, Bembatoka being but a village.

Bembex (i.e. 'whirl'), a genus of solitary sand-wasps (Sphegidae), represented by numerous species in most parts of the world. They are roughly wasp-like in appearance, with broad heads and very large eyes, and make a loud buzz during their rapid flight. The female bembex burrows a hole in the sand, and there deposits her eggs, but before closing it up collects a store of flies, on which the larvæ at first subsist. See WASP.

Bembo, PIETRO, one of the most celebrated Italian scholars of the 16th century, was born in Venice, May 20, 1470; having studied at Padua and Ferrara, he early devoted himself to polite literature. He edited the Italian poems of Petrarch, printed by Aldus in 1501, and the *Terzium* of Dante, 1502. In 1506 he proceeded to the court of Urbino, where he resided until 1512, then went to Rome, and was made secretary to Pope Leo X. On the death of that pope, Bembo returned to Padua, where he became a liberal patron of literature and the arts, as well as a prolific writer himself. In 1529 he accepted the office of historiographer to the republic of Venice, and was also appointed keeper of St Mark's Library. In 1539 Bembo, who had taken only the minor ecclesiastical orders, was unexpectedly presented with a cardinal's hat by Pope Paul III., who afterwards appointed him to the dioceses of Gubbio and Bergamo. He died January 18, 1547. Bembo united in his character all that is amiable. He was the restorer of good style in both Latin and Italian literature. His taste is said to have been so fastidious with regard to style, that he subjected each of his own writings to forty revisions previous to publication. Some of them are marred by the licentiousness of the time. Among his works may be mentioned the *Rerum Veneticarum Libri XII.* (Venice, 1551; Italian ed. 1552); his little

treatise on Italian prose, which marked an era in Italian grammar; *Gli Asolani*, a dialogue on Platonic love; *Rime*, a collection of sonnets and canzonets; and his Letters, Italian and Latin. His *Tutte Opere* were published at Venice in 4 vols. in 1729, and often since.

Bembridge Beds, a division of the Oligocene strata, resting on the Osborne, and capped by the Hamstead series, are principally developed in the Isle of Wight. Edward Forbes arranged the Bembridge Beds in four divisions, thus: (1) The upper mails and laminated gray clays, which form the basement bed of the 'black band,' the lowest member of the Hamstead series. They are distinguished by the abundance of *Melania turretesima*. (2) Unfossiliferous mottled clays, alternating with fossiliferous marls and clays, whose characteristic organisms are *Cerithium mutabile* and *Cyrena pulchra*. (3) The oyster-bed, consisting of greenish marl, and containing immense quantities of a species of oyster (*Ostrea vectensis*), accompanied with *Cerithia*, *Mytili*, and other marine mollusca. (4) The Bembridge limestone, generally a compact, pale-yellow, or cream-coloured limestone, but sometimes vesicular and concretionary, and containing occasionally siliceous or cherty bands. This is interstratified with shales and friable marls. All the beds are fossiliferous, containing numerous land and fresh-water shells. One bed is composed almost entirely of the remains of a little globular Paludina. Shells of *Lymnea* and *Planorbis* are abundant, and are accompanied with the spirally striated nucules of two species of *Chara*, water-plants which have been well preserved because of the large quantity of lime which enters into their composition. In this division have been found the mammalian remains of the species of *Palæotherium* (q.v.) and *Anoplotherium* (q.v.), which characterise the gypseous deposits of Montmartre.

Bemersyde, an estate with an old mansion, in Berwickshire, near the Tweed, $3\frac{1}{2}$ miles E. of Melrose, held since the 12th century by the Haigs, was in 1921 given by subscribers to Earl Haig. See an excellent monograph by John Russell (1881).

Ben (Heb. and Arab., 'son'), often used in connection with the father's name to form Jewish and Arabic personal names, and consequently used, owing to the lack of family-names among the Semitic peoples, to form patronymics—thus Ali Ben Hassan = Ali, son of Hassan. The Hebrew form *Ben* is familiar to us from its use in Bible names—e.g. Benhadad, 'the son or worshipper of Hadad' or Adad, the chief idol of the Syrians; Benoni, 'son of my pain'; Benjamin, 'son of the right hand,' &c. Similarly, many Jews have formed with this prefix new family-names, as Benary = the son of Ari, analogous to English names in -son. The Arabs, Persians, and Turks often make the prefix into *Ibn* (*Ebn*); the Jews, under Arabic influ-

ences, *Aben*, *Aven*, as in Aben Esra. The plural, *Beni*, is found in the names of many Arab tribes—as Beni Omayyah, 'the sons of Omayyah,' the family known in history as the Omniades; and sometimes in the names of places—as Beni-Hassan (see BENI-ISRAEL). The corresponding word in Aramaic is *Bar*, as in Simon Bar-jona.

Ben, or BEINN, the Gaelic and Irish form (Welsh *Pen*) of a Celtic word signifying 'mountain' or 'mountain head.' It occurs, usually as a prefix, in the names of a great many mountains and places within the British Isles, as *Ben Nevis*, *Ben Macdhui*, The Twelve *Pins*, *Pennigant*, *Penzance*; and it appears in many continental names, as the *Pennine* Alps, the *Apennines*, and *Pindus*.

Ben, OIL OF, a fluid fixed oil, obtained from the seeds of the Horse-radish Tree (*Moringa pterygosperma*), found in India and Arabia, and other species. The seeds are called Ben Nuts, and are roundish, with three membranous wings. The oil has several properties which make it of special value to perfumers and watchmakers. When exposed to cold, it deposits a white flaky matter; and when this is removed, an oil is left which is most suitable for watches owing to its non-liability to freeze. Oil of ben is also used to extract the odorous principles from flowers; and as it is not liable to turn rancid, it is much prized in the manufacture of perfumes, although its frequent adulteration with other oils has tended to restrict its use.

Benares (*Bandras*), the most sacred city of the Hindus, and one of the principal towns of North India, situated on the left or northern bank of the Ganges, 420 miles by rail from Calcutta, and 74 from Allahabad. After Lucknow it is the largest city in the United Provinces of Agra and Oudh. It skirts the Ganges for 3 miles, and the high bank is lined continuously with broad flights

The Burning Ghat, Benares.

of stairs or *ghâts*, leading to the innumerable temples and large substantial houses, which present towards the river an imposing array of towers and pinnacles and richly carved façades. The river takes a great crescent-like sweep at this point, and the view of the city is one of the most striking in the world. Benares, however,

is disappointing internally, the streets being mere narrow lanes between the lines of tall, dismal houses. But the crowds of priests and pilgrims on the ghats and at the temples, the sacred bulls wandering at large, and even the wares exposed for sale, all point to the religious character of the place. Among the chief buildings are the Nepalese Temple; Aurungzebe's mosque, with its two minarets 147 feet high; Raja Jai Singh's observatory; the Gopal Mandir, wealthiest of all the temples; the Bisheswar or Golden Temple of Siva, the holiest of all; and the famous Monkey Temple, in the suburbs. Other points of special interest are the well of Mani Karnika, formed of Vishnu's sweat; the Juana-vapi, or 'pool of knowledge'; and the Lat Bhairo, a portion, it is believed, of one of Asoka's pillars. To bathe in the Mani Karnika is to be cleansed from all sins for time and eternity. At the Burning Ghat the bodies of Hindus are reduced to ashes. The city counts 1450 Hindu temples or shrines, most of them small, and 272 Mohammedan mosques. The Hindu University (residential and teaching; founded 1915-16) is now responsible for the Central Hindu College, founded by Mrs Besant; Queen's College, a government institution, is affiliated to Allahabad University. Notable buildings are the hospital and the town-hall. The great Dufferin (railway) Bridge, opened in 1887, crosses the Ganges in sixteen spans. Its length without approaches is 3578 feet. Formerly there was only a bridge of boats, withdrawn during the floods. Benares draws immense revenues from the thousands of pilgrims who visit it from all parts of India. It has a considerable trade, not only in country produce, but in English goods, jewellery, and precious stones. Its brass-ware, kinob or gold-cloth, and lacquered toys are famous. Pop. (1881) 191,025; (1891) 222,420; (1911) 203,804; (1921) 199,993—three-fourths Hindus.—A city of great antiquity, Benares (Sansk *Vārāṇasī*) was for 800 years the headquarters of Buddhism. In the 4th century B.C. it reverted to the ancient faith, of which it has ever since been the metropolis. It has been in the hands of many temporal rulers—the Rajput princes, the Mogul emperors, the Oudh nawabs—being ceded by the latter to the English in 1775. There was a rising here during the Mutiny in 1857, but it was promptly dealt with, and the constant passage of troops from Calcutta to the north kept the city free from disturbance. The western suburb of Sikrol (Secrole) contains the military cantonments and European quarter; the suburb of Sigra is the seat of most of the missionary institutions.—The district has the hottest and dampest climate in the United Provinces, the mean temperature being 77°, and the annual rainfall about 40 inches. See books on the city, also called 'Holy Kasi,' by E. B. Havell (1906), and W. Phillips Cape (1909).

Benares, an Indian state constituted in 1910-11, includes Bhadohi, Kera Mangraur, and (since 1918) Ramnagar, all in Mirzapur district; area, 1000 sq. m.; pop. 363,000.

Benavente, a town of Spain, 34 miles N. of Zamora, is overlooked by a huge half-ruined castle, and is now a dull and poverty-stricken place, built chiefly of mud cottages. It was here that Moore's retreat commenced, 28th December 1808. Pop. 6700.

Benbecula, one of the Hebrides or Western Isles of Scotland, between North and South Uist, 20 miles W. of Skye, and belonging to Inverness-shire. Measuring 6 or 7 miles either way, it is nearly 36 sq. m. in area, low and flat, and consists chiefly of bog, sand, and lake, resting on a substratum of gneiss rock, with a very broken coastline. Nearly three-fourths of the area are under crofts and farms. Pop. 1300.

Benbow, JOHN, admiral, was born in 1653, the son of a Shrewsbury tanner. He entered the navy as a master's mate in 1678, but it was as captain of a merchantman that he first distinguished himself in a bloody action with Sallee pirates (1686). After the Revolution he re-entered the navy, and received his first commission as third-lieutenant, June 1, 1689; but before the close of the same year he was appointed in succession captain to three men-of-war, and by 1696 had risen to be rear-admiral. The most memorable of all his exploits was his last, where his stubborn valour contrasted nobly with the disloyal behaviour of his captains. Off Santa Marta, in the West Indies, on 19th August 1702, he came up with a superior French force under Du Casse. For four days he kept up a running fight with the enemy, almost deserted by the rest of his squadron. On the morning of the 24th his right leg was smashed by a chain-shot. His officers consoled with him. 'I had rather have lost them both,' said the sturdy admiral, 'than have seen this dishonour brought upon the English nation. But, hark ye—if another shot should take me off, behave like men, and fight it out!' As soon as his wound was dressed he was carried to the quarter-deck, and directed the fight while it lasted. The enemy sustained severe loss; but the behaviour of the other captains, who actually refused to obey the admiral's signals, made the contest hopeless, and Benbow sailed away to Jamaica. He died of his wound at Port Royal, on the 4th November. The recusant officers were tried by court-martial, and two captains were shot. Cowardice is none so common among English naval officers that we can rest content with that as an explanation of the strange conduct of Benbow's captains in their mutinous disobedience to his orders. Indeed, it is more than likely that their disaffection was to a large extent a personal matter, and that the 'honest, rough seaman,' by his overbearing and bullying nature, had made himself as hateful to his higher officers as he was popular with his crew for his off-hand manners and personal courage.

Bench, the high seat of the court-room or chamber where judges sit to administer the laws, or the platform on which the chairs for the judges are placed. The court of King's or Queen's Bench was originally so called because in it the sovereign sat in person when he administered justice. The court of Common Pleas was also called Common Bench. The term bench is also applied in America as in Britain to the judges themselves as a class; thus, we speak of the *bench* and *bar*. It has likewise, popularly and conventionally, an ecclesiastical application, the bishops of the Church of England being, as a body, sometimes designated by it; hence the expression, 'Bench of Bishops.' So also in the Episcopal and Methodist-Episcopal churches in the United States. 'Benches' is the ancient name of the governing bodies of the four Inns of Court (q.v.). See COMMON LAW, BANC.

Bench-warrant is a warrant issued by the court, before which an indictment has been found to arrest the accused, that he may appeal and find bail for his appearance at the trial. It is used extensively in the United States to bring into court persons who have neglected to obey an order of court, such as delinquent jurymen.

Bencoelen, capital of a Dutch residency on the SW. coast of Sumatra. Owing to the surf and coral reefs, landing here is difficult. The site is low and swampy, and the houses are mostly built on bamboo piles. There is a lighthouse; and the town is defended by a fort. Rice, coffee, maize, sugar-cane, the coconut, and other fruits are grown;

pepper and camphor are the chief exports, but trade has declined. Bencoelen was founded by the English (1686), but was ceded to the Dutch by the London treaty of 1825. Pop. of town, 12,000; of residency, with an area of 10,000 sq. m., 260,000.

Bend, in Heraldry, one of the figures known as Ordinaries, consists of the space contained between two parallel lines crossing the shield diagonally from dexter chief to sinister base (fig. 1). It is said to occupy a fifth part of the shield unless charged, when it occupies a third part. Its diminutives are the *Bendlet*, which is half its width (fig. 2), the *Cotise*, one-fourth (generally borne in pairs flanking the bend), and the *Ribbon*, one-eighth of its width. In early Heraldry the bend was used as a difference or mark of cadency as well as an original bearing.

The *Bend-sinister* is an occasionally occurring variety of the bend, drawn from sinister chief to dexter base (fig. 3). The *Scarpe* is its diminutive; and that well-known mark of illegitimacy, the *Baton-sinister* (q.v.), is also so accounted.

Charges placed in the direction of a bend are said to be *bendwise*, and when a bend is charged with other figures, the charges on it are understood to be placed bendwise. The term *bend*, when applied to several charges, differs from *bendwise*, in so far as it has reference to the relative position of the charges, not the direction in which each charge lies, as will be understood from the figure,

where the three crosses botonné are placed *palewise in bend* (fig. 4). A field divided by a diagonal line in the direction of a bend is said to be *parted per bend* (fig. 5).

Bendy is a term applied in Heraldry to a field divided into four or a larger even number of parts by lines drawn diagonally, or in the direction of a bend as in the figure, *Bendy* of six argent and azure.

Benda, GEORG, the most distinguished of a notable musical family, born at Jungbunzlau, in Bohemia, in 1721, and distinguished as a pianist, violinist, and composer, died at Köstritz in 1795. He was bandmaster to the Duke of Gotha (1748-87), and in this period produced several operas and cantatas, such as *Ariadne auf Naxos* and *Medea*.

Bendemann, EDUARD, painter, was born in Berlin in 1811, and studied under Schadow. As early as 1832 his great picture of the Captive Jews was exhibited at Berlin, and in 1837 he gained the gold medal at Paris. In 1838 he was appointed professor of the Academy of Art at Dresden. Here he was intrusted with the execution of the larger frescoes in the palace, and on these his fame chiefly depends. In 1858 he succeeded his

father-in-law as director of the Düsseldorf Academy. He died 27th December 1889.

Bender, or **BENDERY**. See TUGHINA.

Bender Abbas, or **BANDER ABBAS**, also called **GOMBROON**, a seaport of Persia, in the province of Kirman, stands on the Strait of Ormuz, opposite the island of that name. Bender Abbas owed its name and importance to Shah Abbás, who, assisted by the English, drove the Portuguese in 1622 from Ormuz, ruined that seaport, and transferred its commerce to Gombroon. For a while the new town prospered; but at present it is a wretched place of about 8000 inhabitants, mostly Arabs.

Ben'digo, at one time called Sandhurst, the centre of a rich gold-bearing district in Victoria, Australia, 101 miles by rail NNW. of Melbourne. The discovery of gold was made in 1851, and the field at once became second only to Ballarat. Later on it developed exceptional importance as a quartz-reefing field, and it is still the richest in Victoria, although Coolgardie in Western Australia far surpasses it, and Mount Margaret (W.A.) is slightly richer. There are many deep shafts, one of more than 4600 feet. The city, which has an excellent water-supply and good public gardens, has been a municipality since 1855. It has many fine public buildings, banks, &c., and the breweries, iron-foundries, and brick-fields usual in a town of the size. It is also an important railway centre, being the junction of lines from Melbourne (*via* Castlemaine) and Kilmore, and from Echuca, Swan Hill, and the mallee districts on the north and north-west. Pop. 33,000.

Benedek, LUDWIG VON, an Austrian general, born in 1804 at Oedenburg. He commanded a regiment in Italy in 1847, and distinguished himself at Mortara and Novara. In 1849 he commanded in Hungary, and took an important share in several battles, being twice wounded. In the Italian campaign of 1859, he drove back the Piedmontese at Solferino with great slaughter. In 1866 he commanded in the war with Prussia, but after the defeat of Sadowa was superseded and court-martialled. He died 27th April 1881.

Beneden, PIERRE JOSEPH VAN (1809-94), born at Mechlin, became professor of zoology and paleontology at the Catholic university of Louvain in 1836, and wrote on the cetacea, parasites, and other departments of natural history.—His son EDOUARD (1846-1910), professor at Liège, was an eminent embryologist and cytologist.

Benedetti, VINCENT, COUNT, a French diplomatist, born in 1817 at Bastia, in Corsica, was appointed in 1855 director of political affairs to the foreign minister, and in this capacity edited the protocols of the Congress of Paris in the following year. He was appointed ambassador at Turin in 1861, and at Berlin in 1864. Benedetti drew up the draft of a secret treaty between France and Prussia in 1870; and it was he who made at Ems the demand about the Hohenzollern candidature that led to the war. In *Ma Mission en Prusse* (1871) and *Studies in Diplomacy* (Eng. trans. 1895) he defends his own policy and throws all blame on Bismarck. He retired to Corsica, practised at the bar of Ajaccio, and died 28th March 1900.

Benedi'cité, or the Song of the Three Children, a canticle from the Apocrypha forming part of the prayer of Abednego in the fiery furnace. It was sung in the Christian Church as early as the time of St Chrysostom, and is used in the Anglican Church in the morning services when the *Te Deum* is not sung.

Benedict is the name of fifteen popes. **BENEDICT VIII.**, son of Count Gregory of Tuscoli, was elected in 1012, but was driven from Rome by the anti-pope Gregory. In 1014 he was restored to the

papal chair by the Emperor Henry II., and afterwards defeated the Saracens, and took from them, with the help of the Pisans and Genoese, the island of Sardinia; and also various places in Apulia from the Greeks, by the help of Henry. He distinguished himself as a reformer of the clergy, and interdicted, at the synod of Pavia, both clerical marriage and concubinage. He died in 1024.—BENEDICT IX., a nephew of the preceding, obtained the papal throne by simony in 1033, at the age of eighteen; but in 1038 the Romans rose in indignation, and banished him on account of his almost unexampled licentiousness. By aid of bribery he was several times reinstalled, and as often formally deposed, only to return again by the same means. The Emperor Henry III., to remove such gross scandals from the church, deposed all the three popes—Benedict, Sylvester, and Gregory, and caused Suidger, Bishop of Bamberg, to be elected as Clement II.; but on his death, in 1047, the deposed Benedict IX. again corruptly regained the papal see, and held it for eight months, when he was displaced, first by Damasus II., and afterwards by Leo IX. He died in the convent of Grotta Ferrata in 1056.—BENEDICT XIII. is a title assumed by two popes, *Peter de Luna*, a Spaniard, chosen by the French cardinals in 1394, and recognised only by Spain and Scotland up to his death in 1424; and *Vincenzo Marco Orsini* (1724–30), a learned and well-disposed man, of simple habits and pure morals, who unfortunately yielded himself to the guidance of the greedy and unscrupulous Cardinal Coscia, who greatly abused the confidence reposed in him. Benedict always exhibited great moderation in politics, and an honourable love of peace, and was instrumental in bringing about the Seville treaty of 1729. During this pontificate a remarkably large number of saints, chiefly from the monastic orders, were added to the calendar.—BENEDICT XIV. (Prospero Lambertini), the most worthy to be remembered of all the pontiffs so named, was born at Bologna in 1675. Before his elevation, he had distinguished himself by extensive learning, and by marked ability in the lower offices. Succeeding Clement XII., he began his pontificate, in 1740, with several wise and conciliatory measures; founded chairs of physic, chemistry, and mathematics in Rome; revived the academy of Bologna, and instituted others; dug out the obelisk in the Campus Martius, constructed fountains, rebuilt churches; caused the best English and French books to be translated into Italian; and in many other ways encouraged literature and science. His piety was sincere, enlightened, and tolerant, and his doctrines were well exemplified in his practice. He was extremely concerned for the morals of the clergy, and established a board of examiners for all candidates to vacant sees. Two important bulls were promulgated by him, denouncing such accommodation of Christian doctrines and rites to heathen beliefs and usages as the Jesuits had practised in the East. The only accusation brought against him by his Roman subjects was 'that he wrote and studied too much, but ruled too little,' or left affairs of business too much in the hands of the Cardinal Valentine. He died 3d May 1758.—BENEDICT XV. (Giacomo della Chiesa) was born 21st November 1854, of a noble Italian family, at Pegli, near Genoa. He studied law, but was ordained in 1878. Five years later he became secretary to the Papal Embassy at Madrid, and in 1887 secretary to Cardinal Rampolla. In 1907 he became archbishop of Bologna, in May 1914 a cardinal, and, after an unusually short interval, was elected pope in September. He made several ineffectual efforts to end the Great War. During his pontificate official relations with France and Great Britain were resumed. He died 22d January 1922.

Benedict, St, the founder of Western monachism, was born of a wealthy family at Nursia, near Spoleto, in 480 A.D. At an early age he was sent to the schools of Rome, but soon grew dissatisfied with the sterile character of the instruction dispensed. The world to the boy seemed full of distractions, impurities, and ignorance; it was difficult to resist, by the ordinary safeguards of virtue, the colossal evils with which men were environed; only, therefore, in the devotions of religion, in the holy silence of solitary meditation, did Benedict see a safe refuge from the sins of the time, and the possibility of realising a spiritual strength which would enable him to stem the flood of corruption. He resolved to leave the city, and betake himself to some deep solitude where the murmur of the world would be inaudible, and alone in the rocky wilderness wrestle with his own nature, until he had conquered it and laid it a sacrifice on the altar of God. In pursuance of this resolution, when he had only reached the age of fourteen, he departed from Rome, accompanied for the first 25 miles by the nurse whom his parents had sent with him as an attendant. He then left her, and retired to a deserted country lying on a lake, hence called *Sublaqueum* (now Subiaco). Here, in a cavern (which afterwards received the name of the Holy Grotto), he dwelt for three years, until his fame spread over the country, and multitudes came to see him. He was now appointed abbot of a neighbouring monastery, observing, or rather neglecting, the oriental rule; but soon left it, as the morals of the half-wild monks were not severe enough. This, however, only excited a livelier interest in his character, and as he lived in a period when the migration and interfusion of races and nations were being rapidly carried on, he could not fail to draw crowds of wanderers about him. Wealthy Romans also placed their sons under his care, anxious that they should be trained for a spiritual life. Benedict was thus enabled to found twelve monasteries, over each of which he placed a superior. The savage Goths even were attracted to him, and employed in the useful and civilising practice of agriculture, gardening, &c. He now sought another retreat, and, along with a few followers, founded a monastery on Monte Cassino, near Naples, afterwards one of the richest and most famous in Italy. Here he extirpated the lingering relics of paganism, and had his celebrated interview with Totila, king of the Goths, to whom he spoke frankly and sharply on his errors. In 515 he is said to have composed his *Regula Monachorum*, in which he aimed, among other things, at repressing the irregular and licentious life of the wandering monks, by introducing stricter discipline and order. It eventually became the common rule of all Western monachism. The monasteries which Benedict founded were simply religious colleges, intended to develop a high spiritual character, which might beneficially influence the world. To the abbot was given supreme power, and he was told to acquit himself in all his relations with the wisdom of God and of St Benedict. The discipline recommended is milder than that of oriental monachism with regard to food, clothing, &c.; but enjoins continual residence in the monastery, and, in addition to the usual religious exercises, directs that the monks shall employ themselves in manual labours, imparting instruction to youth, copying manuscripts for the library, &c. By this last injunction, Benedict, though this was not directly intended, preserved many of the literary remains of antiquity; for the injunction, which he gave only with regard to religious books, was extended afterwards to many secular productions. It is remarkable that the founder of the most learned of all the monastic orders was himself so

little of a scholar that St Gregory the Great described him as being '*scienter nesciens, et sapienter indoctus*'—learnedly ignorant, and wisely unlearned. St Benedict died March 21, 543.

Benedict, SIR JULIUS, a musician and composer, German by birth, but after 1836 resident in England. Born November 27, 1804, at Stuttgart, where his father was a Jewish banker, he studied first under Hummel at Weimar, and afterwards under Weber at Dresden. On Weber's recommendation, he was, in 1824, made musical director of the German Opera, Vienna; and he afterwards was appointed to the conductorship of the San Carlo Theatre in Naples. While in Naples, he produced an opera buffa called *Giacinta ed Ernesto*, and an opera seria, *I Portoghesi in Goa*. Both were too German to suit the Italian taste, but later they were well received at Stuttgart. In Paris, and afterwards (1835) in London, he appeared with great success as a pianist. In 1836 he took up his permanent residence in London, and was, during that year, director of the opera buffa at the Lyceum, where he produced an operetta, composed in Naples, *Un Anno ed un Giorno*. Turning his attention afterwards to English opera, he composed *The Gipsy's Warning* (1838), *The Brides of Venice* (1844), and *The Crusaders* (1846), three works which, translated into German, have been well received in the composer's native country. He conducted the opera in Covent Garden Theatre in 1843 and 1844, and the Norwich Musical Festival in 1845, and thereafter conducted the Monday Popular and numerous other concerts and great musical gatherings in London and in the provinces, besides being a successful pianoforte teacher. In 1850 he conducted at Jenny Lind's concerts in America. In 1860 he produced a cantata, *Undine*, at the Norwich Musical Festival, which was very well received. His *Lily of Killarney*, first given in 1862 at Covent Garden, was his greatest operatic success. He produced a cantata, *Richard Cœur de Lion* (1863); an opera di camera, *The Bride of Song* (1864); and the cantatas *St Cecilia* (1866) and *Graziella* (1882). His oratorio, *St Peter*, written for the Birmingham Musical Festival, 1870, was perhaps his masterpiece; it met with extraordinary success. His first symphony also was received with great favour in 1873. His music possesses abundance of fresh and pleasing melody, and shows the hand of a consummate master, without, however, any very pronounced individuality of style. In his earlier works the score owed something to Rossini, but his later compositions betray more of the influence of his master, Weber. In style and feeling, however, they are singularly English to be the composition of a foreigner. He was knighted in 1871, and was a corresponding member of the French Academy. He died in London, 5th June 1885. He wrote on Mendelssohn and on Weber.

Benedict Biscop, a great churchman of Anglo-Saxon times, was born about 628 of a good Northumbrian family. At first in the service of King Oswy, he assumed the tonsure in the Benedictine monastery of Lerins, after his second journey to Rome. On his return to England from his third journey, he was appointed abbot of St Peter's at Canterbury, but this office he held only for two years. He made yet another pilgrimage to Rome, and soon after his return received from Egrith of Northumbria, in 674, a grant of land between the Wear and the Tyne. Here he founded a monastery, and endowed it with numerous books which he had collected in his visits to Rome. 'He was,' says William of Malmesbury, 'the first person who introduced in England constructors of stone edifices, as well as makers of glass windows.' In 682

he founded a second monastery at Jarrow. Himself a man of the loftiest character, he did much to advance learning and culture in the church, and to his careful fostering of learning we owe his great pupil Bede. He died 12th January 690.

Benedictine, a liqueur, first made at the monastery of Fécamp early in the 16th century, and since the French Revolution manufactured by a secular company there. See LIQUEUR.

Benedictine Editions. See MAURISTS.

Benedictines, the general name of all the monks and nuns following the rule of St Benedict (480-543). He founded his first twelve monasteries at Subiaco, near Rome; thence he passed to Monte Cassino, near Naples, where he wrote his *Rule*, and founded the abbey which is still famous. In his lifetime his disciple, St Placid, spread his order in Sicily; and St Mamus in France. St Gregory the Great was the first (590-604) of the fifty Benedictines who have occupied the papal throne, a list which includes such names as St Leo IV., St Gregory VII., and St Pius VII., and which ends with Gregory XVI. (1831-46). St Augustine, the disciple of Gregory the Great, brought the Benedictine rule to England along with the Christian faith, and became the first of a long list of Benedictine archbishops of Canterbury. The English Benedictine, St Boniface, preached the faith in Germany, and founded there the great abbey of Fulda. Ansgar, the apostle of Denmark; Willibrord, of the Frisians and Dutch; Adalbert, of the Bohemians; and Casimir, of the Poles, were all Benedictines. Benedict Biscop, Bede, and Anselm in England; Isidore, Leander, and Ildefonsus in Spain; Peter Damiani in Italy, and Bernard in France, are names which illustrate the hold this order had upon the teaching of the Catholic Church. As early as 1354 the order had numbered 24 popes, 200 cardinals, 7000 archbishops, 15,000 bishops, 1560 canonised saints, and 5000 holy persons worthy of canonisation, a number since increased to 40,000. It had possessed 37,000 monasteries, 20 emperors, 10 empresses, 47 kings, 50 queens, and an immense number of royal and noble persons. In the 15th century there were 15,107 Benedictine monasteries. The Reformation left not more than 5000.

The Benedictines were grouped into 'orders' and 'congregations,' named after their first abbey, their founder, their patron saint, or their country. The first of these was established at the abbey of Clugny (q.v.) in 910. At Cîteaux (*Cistercium*) the Cistercians (1098) were organised. In Italy St Romuald founded the order of Camaldoli (1009), St John Gualbert that of Vallombrosa (1070), St William that of Monte Vergine (1119). Other congregations were named from Fontevault (1099), Tiron (1109), and Savigny (1112). The Silvestrines (1231) and Celestines (1274) bear the names of their founders; the Olivetans (1319) that of their first abbey. The congregation of Monte Cassino was formed by the union of several abbeys in Italy in 1415, and still exists, though much shorn of its strength. The great abbey of St Paul's in Rome belongs to it. The principal congregation in Germany was that of Bursfeld, which disappeared with the Reformation; but in 1868 the congregation was re-established at Beuron in Hohenzollern-Sigmaringen, and it has now several daughter-abbeys. In Austria and neighbouring countries a score survive out of a much larger number of independent abbeys, of which many date back to the 8th and 9th centuries. The principal are Salzburg, Melk, and Krems in Austria; Martensberg in Hungary. In 1712 a congregation of Armenian Benedictines established itself at San Lazzaro, near Venice, under the name of

their founder Mechtar, and still continues a source of religion and learning for its mother-country. In France the congregation of St Vanne was erected in 1600; along with that of Tiron it was absorbed into that of St Maur in 1627 (see MAURISTS).

The Revolution of 1792 swept all away, but in 1837 D. Gueranger founded the 'French Congregation' at Solesmes; the law of 1903 dispersed the congregation, some of whom established themselves in England. In 1905-10 there were in all in the 'Benedictine Federation' 16 congregations, with 155 monasteries and 5940 monks; besides 142 monasteries of Camaldolese, Vallombrosans, Cistercians and Trappists, Sylvestines, Olivetans, and Mechtarists, with 5347 religious in them. The English congregation was founded in 1300 by the union of all the English monasteries then existing. It included, among the 113 numbered by Tanner, all the greater abbeys and cathedrals, and four other abbeys which have since become cathedrals of England. It was despoiled at the Reformation, and its few surviving members took refuge and multiplied abroad, whence they returned at the French Revolution. In Scotland the principal Benedictine monasteries were Coldingham, Dunfermline, and Iona; Kelso, Kilwinning, Arbroath, and Lindores (Tyronensian); Melrose, Newbattle, Dundrennan, and Kinloss (Cistercian); and Paisley (Cluniac). The abbey of Fort Augustus, the only one now in Scotland, was founded 1878, and in it is perpetuated whatever remained of the Scottish abbey at Ratisbon. During the 19th century the order spread widely in the United States, the mother-abbey being St Vincent's, Pennsylvania. Monasteries have been established also in Australia (one among the aborigines) and in New Zealand. In 1851 a new congregation was erected under the presidency of the abbey of Subiaco, one of the original foundations of St Benedict, and has widely propagated.

The Rule of St Benedict is a modification of that of the eastern ascetics, St Basil, Cassian, &c. It was the first to introduce *Stability*, or the binding of the monk to a permanent abode in a monastery, and in the practice of monastic life till death. This is the first of the Benedictine's three vows; the second is *Conversion of Manners*—i.e. the striving after perfection of life; and the third, *Obedience according to the Rule*, by the tenor of which the monk is bound to chastity, to the renunciation of private property, to retirement from the world, to the daily and public solemnisation of the divine office, and to a life of frugality and labour under filial obedience to the abbot. Hospitality and the other works of mercy, corporal and spiritual, are strongly inculcated in the rule, and among these, Benedictine monks have always given a high place to the work of education and instruction in worldly and religious learning. Both these still form the principal subjects of their employment. From the days of Charlemagne to the 12th or 13th century, the Benedictine monasteries were almost the only repositories of learning; the literary labours of the Maurists in the 18th century are proverbial, and to this day it would be difficult to find a Benedictine monastery without at least its 'internal' school of philosophy and theology. The modern congregation of Beuron is famous for its school of art.

The Benedictine habit consists of a tunic and Scapular (q.v.), over which is worn a long full gown called a *cowl*, with a *hood* to cover the head. The colour is not specified in the rule, and it is conjectured that the early Benedictine wore white as being the natural colour of undyed wool. For many centuries, however, black has been the prevailing colour, whence the term 'black monk' comes to

mean a Benedictine in general, or one who does not belong to certain congregations which have a special colour—e.g. the Camaldolese, the Cistercians and Olivetans wear white, and the Sylvestines blue. The latter are numerous in Ceylon.

St Benedict's twin-sister Scholastica is supposed to have lived under his rule, and Benedictine nuns have always been as numerous as Benedictine monks. At present the number of their convents probably much exceeds that of the monasteries of men.

See *Annales Ordinis Sti Benedicti*, and *Acta Sanctorum Ordinis Sti Benedicti*, by Mabillon; Reyner, *Apostolatus Benedictinorum in Anglia*; *Album Benedictinum* (St Vincent's, Pennsylvania, 1880); *The Holy Rule of St Benedict* (Fort Augustus, 1885); Montalembert, *The Monks of the West* (trans. 1895); Father Taunton, *The English Black Monks of the Order of St Benedict* (1897); Abbot Butler, *Benedictine Monachism* (1919); and MONACHISM.

Benediction (Eccles. Lat. *benedictio*) is a solemn invocation of the Divine blessing upon men or things, and in its simplest form may be considered almost coeval with the earliest expressions of religious feeling. The Sabbath is said to have been blessed. Jacob blessed his two grandsons. Christ 'took bread and blessed it,' and 'lifting up his hands,' blessed his disciples. In the primitive church the custom gradually developed itself in various liturgical forms. In Protestant churches a form of benediction is used at the close of religious services. In the Roman Church a priestly benediction has been defined as a formula of imperative prayer, which, in addition to the desire which it expresses, transmits a certain grace or virtue to the object over which it is pronounced. Such ecclesiastical benedictions are generally accompanied with the sprinkling of holy water and the use of incense, and universally with the sign of the cross. Prescribed forms may be gathered from the missal, breviary, and pontifical, or may be found collected in the *Benedictionale Romanum*. Certain blessings form part of the liturgical services which only occur at stated seasons, as the blessing of the candles on Candlemas Day, of the ashes on Ash Wednesday, and of the palms, the sacred fire, the incense grains, the paschal candle, font and baptismal water, during Holy Week. Many ancient and curious ceremonies are used at the blessing of altars or of church-bells by the bishop. Other objects for which special blessings are provided in the *Benedictionale* are fields, houses, ships, cattle, noxious animals, articles of food, and even railroads and telegraphs. Water mingled with blessed salt for the devotional use of the faithful in church or at home is as a rule prepared every week. This *aqua benedicta* or holy water in turn conveys a blessing to persons or objects aspersed with it. Priests having special faculties for the purpose may bless crosses and rosaries, which only, when so blessed, impart the papal indulgence to those who use them. So great was the importance attached by Roman Catholics to this delegated papal blessing, that in 1571 the English parliament, in retaliation against the pope for attempting to depose Elizabeth, imposed the penalties of premunire on any one who should bring into the realm an *Agnus Dei* (a medal of wax), crosses, pictures, or beads consecrated or hallowed by the Bishop of Rome, or by authority derived from him. The papal benediction conveyed to a dying person carries with it a plenary indulgence. On certain occasions the pope pronounces a solemn benediction *urbi et orbi* (on the city and the world).

BENEDICTION is also the name given in some countries (in French, *Le Salut*) to a brief and popular service of comparatively modern origin in the Roman Church. It consists of certain canticles and antiphons sung in presence of the sacred host,

which is exposed for the occasion on a 'throne' above the altar. The service is concluded by the priest, wrapped in a veil, taking the monstrance which contains the host, and therewith making the sign of the cross over the people, and giving to them in silence the benediction of the most holy sacrament.

Benedictus, (1) the fifth movement of the Mass (q.v.), beginning 'Benedictus qui venit,' following the Sanctus; (2) the canticle of Zacharias (Luke, i. 68-79), used in the Roman service of matin-lands, and thence adopted into the Anglican morning service.

Benedix, JULIUS RODERICK, a German actor, manager, and play-writer, was born at Leipzig in 1811, and died there September 26, 1873. Of his numerous pieces, the best are his comedies, most of which are favourites in Germany, for their humorous, intricate plot, constant change of incident and scene, and natural, but witty, dialogue. His dramatic works fill 27 vols. (1846-74).

Benefice, or BENEFICIUM, was first applied in the Lombard laws and the Constitutions of Charlemagne to the life-interests in land, which were the reward of military service, and afterwards developed into hereditary feudal grants; but is now used in England to denote any kind of church promotion or dignity, but specially a 'benefice with cure of souls,' such as rectories, vicarages, and other parochial cures, as distinguished from bishoprics, deaneries, cathedral preferments, and other ecclesiastical dignities or offices. Some benefices are called *exempt* or *peculiar*, by which is meant that they are not to be under the ordinary control and administration of the bishop; but such exempt or peculiar benefices are nevertheless, so far as relates to pluralities and residence, subject to the archbishop or bishop within whose province or diocese they are locally situated. See DEAN.

There are, in general, four requisites to the enjoyment of a benefice. 1st, Holy orders, or ordination at the hands of a bishop of the established church or other canonical bishop (a Roman Catholic priest may hold a benefice in the Church of England on abjuring the tenets of his church, but he is not ordained again); 2d, Presentation, or the formal gift or grant of the benefice by the lay or ecclesiastical patron; 3d, Institution at the hands of the bishop, by which the cure of souls is committed to the clergyman; and 4th, Induction, which is performed by a mandate from the bishop to the archdeacon to give the clergyman possession of the temporalities. Where the bishop is himself also patron, the presentation and institution are one and the same act, and called the *collation* to the benefice. The spiritual duties of a benefice are those connected with public worship, baptism, marriage, burial, and the administration of the Lord's Supper, with less defined duties of visitation of and intercourse with parishioners. The emoluments of a rector consist of the freehold of the parsonage house, the glebe, the tithes, and other duties; the vicar has only a proportion of these. The rector is liable for the repair of the chancel, and has serious duties in connection with the church and the churchyard, which in the ordinary case are his freehold. (See Cripps or Phillimore on Church Law.) In Scotland, benefices are divided into temporalities or lands and spiritualities or teinds. The former were taken by the crown at the Reformation and erected into lordships in favour of the lords of erection, titulars, and commendators; but in the 17th century most of these estates returned to the crown. These titulars had also rights of drawing teind from other lands, a public grievance, which was settled by the celebrated decrees arbitral of Charles I. The spiritualities, or main body of the teinds, are still held by

the Church of Scotland (see TEINDS, AUGMENTATION, STIPEND). The election of ministers now proceeds under the Patronage Act, 1874. The minister in Scotland has a manse and glebe, but not the same rights in the church or churchyard, as in England. See ADVOWSON, SIMONY, PLURALISM.

Beneficiary is a legal term used in both England and Scotland to denote a person who is in the enjoyment, or is ultimately entitled to the enjoyment, of any interest or estate held in trust by others. The technical term in the law of England is *Cestui que trust* (q.v.). Thus, annuitants, special legatees, and residuary legatees are all beneficiaries. In charitable trusts of a discretionary character there is often doubt as to who the beneficiaries really are, and both under statute and at common law the courts or the commissioners are occasionally asked to reform a charity, which often means changing the class of beneficiaries. Beneficiaries are entitled to protect the trust estate by interdict and injunction against improper acts of the trustees, and also to sue the trustees for an accounting. See TRUST.

Benefit of Clergy. This expression relates to a former state of the law of England, which shows the power of the clergy and the ignorance of the people. The benefit or privilege meant little short of the total exemption of the clerical order, in respect of crimes and offences, from the jurisdiction and authority of the secular magistrate. The only exception to this was the priest being held in custody by the king himself; but even in that case, he could only remain in such regal custody with the pleasure and consent of the bishop, who had entire control over his person, and over the inquiry into his offence. If a priest or 'clerk' happened to be imprisoned by the secular arm, on a criminal charge or capital felony, he was, on the bishop's demand, to be instantly delivered up without any further inquisition; not, indeed, to be let loose upon the country, but to be detained by the ordinary, till he had either purged himself from the offence, or, having failed to do so, had been degraded. The purgation before the church court was arranged entirely in favour of the accused. This state of things continued till the Statute of Westminster the First (1275), which provided that the prisoner must first be indicted before he could be claimed, and then in the reign of Henry VI. it was settled that the prisoner must first be convicted, and might either then claim his clergy by plea declining the jurisdiction, or, as was most usually practised, after conviction, by way of arresting judgment. The test of admission to this singular privilege was the clerical dress and tonsure—i.e. the claimant must be strictly in orders and not a mere assistant. The statute *Pro Clero* (1350), however, extended it to all manner of clerks, and by later practice it was extended to all who could read, whether of the clergy or laity—a mark of great learning in those days—and therefore capable of becoming clerks. Women, however, except professed nuns, were until the Reformation excluded. But laymen could only claim it *once*, and upon so doing were burned on the hand, and discharged; to be again tried, however, by the bishop, whose investigation usually resulted in an acquittal, which, although the offender had been previously convicted by a jury, or perhaps on his own confession, had the effect of restoring him to his liberty, his credit, and his property. The mode in which the test of reading was applied was as follows: On conviction, the felon demanded his clergy, whereupon a book (commonly a psalter) was put into his hand, which he was required to read, when the judge demanded of the bishop's commissary, who was present, *Legit ut clericus?*

and upon the answer to this question depended the convict's fate; if it were simply *legit*, the prisoner was burned on the hand, and discharged; but if *non legit*, he suffered the punishment due to his offence. By a series of statutes most of the serious crimes and all capital crimes had been excluded from benefit of clergy before the end of the 17th century, but it was extended to all persons convicted of clergyable offences, whether they could read or not; and instead of burning on the hand, a discretionary power was given to the judge to inflict a pecuniary fine or imprisonment. Newly-created felonies, which were numerous in the 18th century, were not entitled to the benefit. But all further attempts to modify and improve the law on this subject proving impracticable, the benefit of clergy was at last totally abolished, by statutes of 1779 and 1827; and by a later statute the same was done for the peers.

See Hale's *Pleas of the Crown*, Stephen's *History of the Criminal Law of England*, and a learned essay in Lea's *Studies in Church History* (1904).

Benefit of Inventory, in the Scots law, was a legal privilege whereby an heir secured himself against unlimited liability for his ancestor, by giving up, within the *Annus deliberandi* (q.v.), an inventory of his heritage or real estate, to the extent of which, and no further, was the heir liable. The method of obtaining this privilege was simplified in 1847 and 1868, but it is now superseded by the general declaration in the Conveyancing (Scotland) Act, 1874, that 'an heir shall not be liable for the debts of his ancestor beyond the value of the estate of such ancestor to which he succeeds.' See DEBT, MORTGAGE.

Benefit Societies. See FRIENDLY SOCIETIES; and for the associations sometimes called Benefit Building Societies, see BUILDING SOCIETIES.

Benke, FRIEDRICH EDUARD, professor of philosophy in Berlin, was born in that city in 1798, and studied theology and philosophy, first at Halle, and then at Berlin. In 1820 he commenced lecturing in the latter university, but his lectures were soon interdicted by the minister Altenstein, as his philosophical views were quite opposed to those of Hegel. For three years he taught at Göttingen, but in 1827 his lectures at Berlin were again allowed, and in 1832, on Hegel's death, he was appointed extraordinary professor of philosophy. In March 1854 Benke disappeared suddenly from his residence, and nothing more was heard of him until June 1856, when his body was found in the canal at Charlottenburg. Benke has more affinity with British thinkers than any other German philosopher. His most important works are on psychology, which he insists must be founded on the facts of our consciousness. His system of psychology is therefore what the Germans call 'empirical,' and his method is the Baconian as pursued in natural science.

Beneš, EDUARD, Czech statesman, born in 1884, was a lecturer on sociology in Prague University. A refugee during the Great War, he wrote *Bohemia's Case for Independence* (1917). In the first and subsequent Czechoslovak ministries, including his own (1921-22), he was foreign minister. The 'Petite Entente' was his work.

Benet College. See CAMBRIDGE.

Benevento (ancient *Beneventum*), a city of Southern Italy, capital of a Campanian province of the same name, is situated on a hill near the confluence of the Calore and Sabato, 61 miles NE. of Naples by rail. It occupies the site of the ancient city, out of the materials of which it is entirely built, and is surrounded by walls about 2 miles in circumference. It has a citadel, a fine

old cathedral, some noteworthy churches, and a magnificent arch, erected in 114 A.D. to the honour of the Emperor Trajan, which, with the single exception of that of Ancona, is the best preserved specimen of Roman architecture in Italy. It is an archiepiscopal see, and has a population of about 25,000, chiefly engaged in the manufacture of leather, parchment, and plated goods. The town was in the possession of the Samnites when history first takes notice of it, and it appears to have been captured from them by the Romans some time during the third Samnite war (298-290 B.C.). It was certainly in the hands of the Romans in 274 B.C.; and six years later they changed its name from Maleventum to Beneventum, and made it a Roman colony. The Carthaginians under Hanno were twice decisively defeated in the immediate neighbourhood during the second Punic war. It rapidly rose to be a place of importance under the Roman empire; under the Lombards, who conquered it in the 6th century, it continued to flourish; and at length it became capital of a duchy which included nearly the half of the late kingdom of Naples. This was seized by the Normans; the town was given (1053) to the pope by the Emperor Henry III. Thenceforward, until 1860, when it was united with the kingdom of Italy, Benevento continued, with slight intervals, to be governed through a resident cardinal with the title of Legate. In 1806 it was bestowed by Napoleon, with the title of prince, on Talleyrand; but it was restored to the pope in 1815.—The province of Benevento has an area of 820 sq. m., and a population of 260,000.

Benevolence, in the history of the law of England, was a species of forced loan or contribution, levied by kings without legal authority. It was first so called in 1473, when asked from his subjects by Edward IV. as a mark of good-will towards his rule, but similar compulsory 'free-will offerings' had not been uncommon in former reigns. Under Richard III., in 1484, an act of parliament abolished benevolences as 'new and unlawful inventions,' but spite of this they continued to be exacted by Richard himself and by Henry VII. In 1614 James I. tried, but with little success, to raise money by this expedient, and it was never again attempted by the crown; Charles I. expressly declining to have recourse to it.

Benfey, THEODOR, a great orientalist and comparative philologist, was born of Jewish parents near Göttingen in January 1809. He studied in Göttingen, Munich, Frankfurt, and Heidelberg, devoting himself especially to classical and comparative philology. In 1862 he was appointed to the chair of Sanskrit and Comparative Philology in the university of Göttingen, which he held till his death in June 1881. One of his earliest literary efforts was a translation of Terence (Stutt. 1837); after this, however, he turned his attention almost exclusively to comparative philology, oriental languages, especially Sanskrit, and mythology. In his fifty years devoted with rare enthusiasm and persistency to linguistic studies, he did more than any other scholar to enlarge the boundaries of Sanskrit philology. In comparative philology, though an adherent of Bopp, he deviated from his master in deriving all Indo-European words from *monosyllabic primitive verbs*. This conception depends on his theory of the origin of stem suffixes. These, he holds, are almost all derived from a fundamental form *ant*, which appears in the present participle of verbs. To support this view he assumes the most violent permutations of sounds which set all phonetic laws at defiance. For his theory, see his *Lexicon of Greek Roots* (Berl. 1839), *Short Sanskrit Grammar*

(Lond. 1868), and numerous essays. In Sanskrit he laid a foundation for the true study of the Veda by editing the *Sāma Veda* (Leip. 1848) with glossary and translation; and this work he continued by a scholarly translation of the first *mandala* of the Rig Veda in his magazine *Orient and Occident* (Gött. 1863-64). His Vedic grammar, for which he had been collecting materials for many years, was left unfinished. He also published a *Complete Sanskrit Grammar, Chrestomathy and Glossary* (Leip. 1854), and a *Sanskrit-English Dictionary* (Lond. 1866); and in comparative folklore his principal work was a translation (2 vols. 1859) of the *Panchatantra* (q.v.).

'**Bengal**' (old *Bangālā*), a name given to part of British India, but variously signifying—(1) the old historical presidency which, in pre-Mutiny times, comprised the greater portion of Northern India; (2) the province as it was till 1905, also called Lower Bengal, comprising Bengal Proper (the division of Calcutta and four other districts), Bihar, Orissa, and Chota Nagpur; (3) Bengal as partitioned in 1905, when Eastern Bengal was detached and united with Assam; (4) Bengal as repartitioned in 1912 from Bihar and Orissa and reunited with Eastern Bengal. Bengal had 78,699 sq. m. and 46 millions of inhabitants in 1921; while Bihar and Orissa had 83,181 sq. m. and 34 millions. As divided in 1905, Bengal contained 42 millions of Hindus and 9 of Mohammedans; while Eastern Bengal and Assam had 18 millions of Mohammedans and 12 of Hindus.

The undivided province was the largest and most populous of the twelve divisions of British India, nearly as large as Spain, and half as large again as Great Britain and Ireland: its lieutenant-governor had to superintend an area of 151,000 sq. m. and a population of 75 millions—with the native states, 80 millions, or more than that of the United States of America at that time, and about twice that of the United Kingdom. The census of 1881 gave a population of 66,750,520 in British territory and 2,845,405 in the feudatory states. The following are the census figures for 1911 and 1921, giving a density in Bengal Proper of 592 per square mile, in Bengal States 166:

	Sq miles	Pop 1911.	Pop 1921
Bengal.....	78,699	45,483,077	46,053,177
Bihar and Orissa.....	83,181	34,490,034	33,998,778
Assam.....	58,015	6,713,635	7,598,861
British Territory.....	214,895	86,686,796	88,250,816
Bengal.....	5,398	822,565	896,173
Bihar and Orissa.....	28,648	3,945,209	3,965,431
Assam.....	8,456	346,222	383,672
Feudatory States.....	42,497	5,113,996	5,245,276
Total.....	257,392	91,800,792	93,496,092

Roughly speaking, Bengal comprises the low-lying deltas of the Ganges and Brahmaputra, and the alluvial plains stretching along their lower courses. In the N. it is hemmed in by the Himalayan ramparts; in the SW. it adjoins the hilly region of Chota Nagpur, which forms a continuation of the Central Indian plateau; while on the S. its coastline extends round the top of the Bay of Bengal, from the Hugli to the point at which Chittagong is terminated by the Lower Burma boundary. Although for the most part level, Bengal is diversified in various parts by peaks and spurs thrown out from the great mountain-systems. It is bounded landwards by the native states of Sikkim and Bhutan on the N., by Assam and Upper Burma on the E., by Nepal and Bihar and Orissa on the W. The province is portioned out into five large administrative tracts called divisions, each under a commissioner, Calcutta (or Presidency), Bardwan, Rajshahi, Dacca, and Chittagong. The divisions, Patna, Tirhut, and Bhagalpur, Orissa, and Chota

Nagpur, form the new province of Bihar and Orissa. The commissionerships are again divided into districts, each with a magistrate, and among these may be named the densely peopled metropolitan districts of Hugli (Hooghly), Howrah, and the 24 Parganas; and the rich trading districts of Dacca and Faizpur. The distinctive features of Bengal are its immense network of rivers, the magnificent range of the Himalayas, the luxuriant but fever-haunted Terai at the base of the great mountain-chain, and the trackless forests and jungles of the Sundarbans (Sunderbunds), on the sea-face of the delta—the almost undisputed home of the tiger and rhinoceros. Besides the main streams of the Ganges and Brahmaputra, the chief rivers are the Tista, Hugli (formed by the Bhagirathi and Jalangi), the Damodar, and Rupnarayan. All the rivers are subject to floods, bring down an immense quantity of soil, and thousands of square miles in the delta thus receive a splendid top-dressing every year. The country is so enriched by this system of recuperation as 'to defy the utmost power of over-cropping to exhaust its fertility.' As compared with Northern India, Bengal is remarkable for the absence of large cities. Calcutta, the capital, is one of the largest cities in the world, having in 1921 a population of 1,263,292. But the other towns are small, the next largest being Dacca, with 117,000. On the Hugli, within 20 miles of Calcutta, stand the small French settlement of Chandernagore, the Portuguese Hugli, the Dutch Chinsua, and the Danish Serampur. All these are now places of diminished importance, but they give to the river Hugli a peculiar historical significance; all but Chandernagore have been ceded to England, the Danish town as late as 1845.

The climate of the plains is similar to that of the Indian seaboard everywhere—hot and humid. But on the hills every variety of climate is met with, till the perpetual snow-line is reached. The ordinary range of temperature in the plains is from about 52° F. in the cold season, to 103° in the shade in summer. In good European houses the temperature in the hottest months can be kept down to 95°. The hill-station of Darjiling, at an elevation of 6685 feet, has a mean temperature of 54°. In the eastern districts the average yearly rainfall is over 100 inches, while on the hillsides this is greatly exceeded. Calcutta has only 66, Darjiling 126. Bengal is exposed to the heavy sweep of the Monsoon (q.v.), while cyclonic waves and river inundations are frequent, carrying at times terrible havoc far into the low-lying country. At the same time, earthquakes are not infrequent, and have caused widespread destruction of property. The people are mostly employed in agriculture, and among the chief products are indigo, jute, the opium poppy, oil-seeds, many varieties of rice, cinchona, tea, turmeric, pepper, the silk mulberry, cotton, sugar, and innumerable grains, spices, and drugs. Opium is a government monopoly; and cinchona is chiefly grown at the government plantations at Darjiling. The enormous wealth of Bengal lies in its production of articles of commerce. From its position in relation to the interior, a vast traffic passes through Bengal, much of the wheat of the North-west, and the jute and tea of Assam, finding an outlet at Calcutta. Nearly all the foreign trade belongs to Calcutta. The principal exports are opium, rice, jute, oil-seeds, indigo, cotton, wheat, and hides and skins. A large trade is done in gunny-bags, Calcutta in one year exporting over 600 millions of them. In addition to about 5000 square miles of reserved forests, there are in cultivation over 21 million acres under rice, 2 million acres under wheat and other food-grains, and 1½ million acres under oil-seeds; the other principal crops are sugar, indigo, tobacco, cotton,

and tea. Great interest attaches to the cultivation of tea, which rapidly came to hold a front rank among Indian industries. There are about 300 tea-gardens in Darjiling district and the Terai, including Jalpaiguri; the Assam produce also passes through the province. Systematic forest conservancy has done much to check indiscriminate destruction of timber, and to increase the government revenue (from the 'reserved forests').

Bengal has considerable mineral wealth. In Bardwan coal, iron, and copper are worked, but the iron-smelting has hardly been a commercial success. Of many coalfields, the most important is at Raniganj. The seventy jute and cotton mills around Calcutta are even a more striking indication of industry, employing more than 200,000 hands. This new cotton manufacture in some measure takes the place of the old native industry in fine cottons and muslins, almost annihilated by the competition of Lancashire. Lacquer, sugar, ropes and cables, leather, porcelain and stoneware are also amongst the manufactures. The railways include the Darjiling-Himalayan, one of the most wonderful mountain-railways in the world. Several distinct systems of canals provide for conveyance of goods, and irrigate a vast area of land.

Standing far in advance of the rest of India in education, the enlightened classes in Bengal are largely employed in government service. Of some fifty institutions giving university education, most are affiliated to the university of Calcutta. With engineering, normal, industrial, and other schools, there were in all in 1920 more than 50,000 public educational institutions, with about 1,900,000 pupils, besides over 2000 private institutions, with 67,000 pupils. See the articles INDIA and books there cited, CALCUTTA, BRAHMA SAMĀJ, &c.

Including Eurasians, there are upwards of 45,000 Europeans in the province, of whom 28,000 are in Calcutta and its neighbourhood. Of the Europeans, 12,000 are British-born. In Bengal there are also 1080 Armenians, 3000 Chinese (shoemakers and carpenters in Calcutta), 600 Parsis, and 2000 Jews.

Within the province there is a great variety of race, language, religion, and civilisation. A large proportion of the people are of Aryan stock; but no sharp line can be drawn in race between those called Hindus and those reckoned aborigines or non-Aryan, as many low-caste Hindus are wholly aboriginal in blood. There is within the province every degree of civilisation from that of the English-educated, sceptical Hindu gentleman, to the primitive hillman. The new province of Bengal has 20 million Hindus and 24 million Moslem inhabitants, mainly belonging to the upper classes, and 130,000 are returned as Christians. In Bengal Proper the Santals are the most notable aboriginal stock; in the Indian states are the Kolarian or Dravidian Gonds, Kols, and Bhuiyas, as well as Indo-Chinese tribes.

The history of Bengal is merged in that of India. The Mohammedan conquest dates from 1200. The East India Company made its earliest settlements, purely commercial in character, in the first half of the 17th century. The old settlement was the keystone of the British empire in India; and in the opinion of General Chesney (*Indian Polity*) it remained the one part of India which would be worth retaining were the rest to go. Main facts in the strictly provincial history are the Permanent Settlement of the Land Revenue enacted by Lord Cornwallis in 1793, by which the rights of proprietors were defined and secured in perpetuity; and the Tenancy Act of 1885, a supplement to the older measure, intended to protect cultivators. In 1905 Bengal was partitioned into two divisions. In 1912 the partition of 1905 was reversed, and a fresh division made into Bengal and Bihar and

Orissa. Calcutta at the same time ceased to be capital of India. Under the Government of India Act (1919) Bengal became a governor's province, with diarchical government and a partially elected legislative council. See also INDIA.

Bengal, BAY OF, a portion of the Indian Ocean, of the figure of a triangle. Its southern side, drawn from Coromandel to Malacca, so as merely to leave on the right both Ceylon and Sumatra, may be stated at 1200 miles. The bay receives many large rivers—the Ganges and the Brahmaputra on the north, the Irawadi and Salwin on the east, and on the west the Mahanadi—the Godavari, the Kistna, and the Kaveri. On the west coast there is hardly anything worthy of the name of harbour; while on the east there are many good ports—such as Akyab, Gwa, Maulmain, Tavoy River. The islands in the bay are very numerous, and include the Andaman, Nicobar, and Mergui groups. The monsoons prevail over the whole of the north part of the Indian Ocean, of which the Bay of Bengal is a part, and also over the maritime tracts of Bengal itself. See MONSOON.

Bengalese. See WEAVER-BIRD.

Bengali Language, one of the great Aryan vernaculars of India; see INDIA, and Dinesh Chandra Sen's *History of Bengali Language and Literature* (1912).

Bengal Kino. See BUTEA, KINO.

Bengal Light, or BLUE LIGHT, is a brilliant signal-light used at sea in a case of shipwreck, and in ordinary pyrotechny for illuminating a district of country. It is prepared from nitre, sulphur, and the black sulphide of antimony. The materials are reduced to fine powder, thoroughly dried, and intimately mixed in the following proportions by weight: nitre, 6; sulphur, 2; black sulphide of antimony, 1. The mixture constitutes the Bengal light, and when kindled, immediately bursts into rapid and vivid combustion, evolving a brilliant, penetrating, but mellow light. As the fumes evolved during the combustion of the Bengal light contain an oxide of antimony, and are poisonous, the light cannot be used with safety in rooms or enclosed spaces.

Bengal Quince, the fruit of *Ægle marmelos*. See *ÆGLE*.

Benga'zi, a seaport of North Africa, capital of the district of Cyrenaica, or Barca (q.v.), on the east coast of the Gulf of Sidra; pop. 35,000, including considerable numbers of Maltese, Greeks, Italians, and Jews. The trade is largely with Mediterranean ports, the extensive traffic with the interior having largely passed to Tripoli. Imports include English cottons and woollens, coal and iron. The harbour, which has a lighthouse, is surrounded by reefs, and has been largely silted up with sand. The sponge-fishery on the coast is valuable. When, with Tripoli, this territory was taken by Italy in October 1911, Bengazi was bombarded rather severely. The town is comparatively clean and well built, and possesses a fine bazaar, and several mosques and synagogues, a Catholic church, and a Franciscan monastery. Bengazi is the site of the ancient city of *Hesperis*, which rose to some importance under Ptolemy III., who called it *Berenice*, after his wife. The ruins lie to the north-east of the present town.

Bengel, JOHANN ALBRECHT, a distinguished German theologian and commentator, born at Winnenden, in Württemberg, 24th June 1687. He studied at Tübingen, where, in 1708, he became theological tutor; later in life he held several high offices. He died 2d November 1752. He was the first Protestant author who treated the

exegesis of the New Testament in a thoroughly critical and judicious style. He did good service also in the rectification of the text of the Bible, and was the first to classify the manuscript authorities for the text of the New Testament into families (Asiatic and African). The short notes in his *Gnomon Novi Testamenti* (1742) are invaluable, and have been translated into various languages. They were made much use of by John Wesley in his *Notes on the New Testament*, which forms one of the standards of Wesleyan Methodism. Indeed, Wesley's work may be regarded as little more than an abridged translation from Bengel. An exposition of the Revelation of St John (1740) and a chronological work—the *Ordo Temporum a Principio per Periodos (Economic Divinae Historicae atque Propheticae)* (1741)—gained for Bengel, in his time, a great reputation, some regarding him as an inspired prophet, but the majority as a visionary. In these works he calculated, on the basis he supposed to be laid down in the Apocalypse, that the world would endure for the space of 7777½ years, and that the 'breaking loose and the binding of Satan' would take place in the summer of 1836. See the Lives of him by Burk (2 vols. 1831-37) and Wachter (1865), and Reiff's *Bengel und seine Schule* (1882).

Benghazi. See BENGAZI.

Benguela (also *Benguella*), a province of Angola or Portuguese Western Africa, between the provinces of Loanda on the N. and Mossamedes on the S., the eastern limits of which are not very definitely fixed. It is usually represented as lying between 10° and 15° S. lat. and 12° and 17° E. long. Its surface is generally mountainous, rising from the coast-line inland in a series of terraces; several important rivers flow through it in a north-west direction to the Atlantic. These rivers have numerous affluents, and water is everywhere so plentiful that it may be found by digging two feet beneath the surface. Sulphur, copper, and petroleum are found in the mountains, and also gold and silver in small quantities. The description of flora and fauna given for Angola (q.v.), of which Benguela is a part, of course applies equally to this latter district.—**SÃO FELIPE DE BENGUELA**, the Portuguese capital of the above region, is situated on a level plain near the sea, backed by a line of hills, in 12° 33' S. lat. It is very unhealthy, and has a straggling appearance. The loss of trade has, moreover, given it an air of desolation. It was a great slave-station at one time, exporting annually 20,000 slaves to Brazil and Cuba. The population is about 2500. Lobito Bay, 20 miles farther north, with a good harbour, and a railway destined to reach Katanga and connect with the general system of African railways, is a progressive port, which bids fair to become the gateway of Central Africa.

Bení, a river of South America, in Bolivia, rises in the La Paz Cordillera of the Andes, at a height of almost 12,000 feet, and collects all the streams that rush down from the mountains between 14° and 18° S. lat. Flowing through the department of its own name, it joins the Mamore, after a course of over 1000 miles, to form the Madeira, one of the largest affluents of the Amazon. The current is very strong, and there are numerous rapids, but the river is traversed by the rafts and canoes of india-rubber collectors and bark-gatherers.

Benicarló, a poor, dirty, walled town of Spain, in the province of Castellón, 84 miles SW. of Tarragona. Pop. about 10,000, who manufacture 'full-bodied' wines for export to Bordeaux, where they are used in cooking clarets for the English market. Fiery brandy and carobs are also exported.

Benicia, a city of California, formerly capital of Solano county and of the state, is situated on the Carquinez Strait, which connects the San Pablo and Suisun bays, 30 miles NE. of San Francisco. It has a commodious harbour. Cement, leather, and flour are manufactured. Pop. 2700. The 'Benicia Boy' was John C. Heenan, the pugilist, who fought in England with Tom Sayers in 1860.

Beni-Hassan, a village of Upper Egypt, on the east bank of the Nile, remarkable for the catacombs excavated in the low hills that rise in this part of the valley. These chambers are about thirty in number, and are supposed to have been used as sepulchres by the principal inhabitants of Hermopolis, a city that stood on the opposite side of the river. Some measure 60 by 40 feet, and pillars, left smooth for hieroglyphics, are cut out of the rock in imitation of the columns that support the roofs of buildings. The sides of the caverns are covered with paintings representing Egyptian customs; and these, although not so artistic as those in the Theban catacombs, are of earlier date.

Beni-Israel ('sons of Israel'), a remarkable settlement, evidently of Jewish origin, existing in the west of India, chiefly in Bombay and some coast towns. They are believed to have reached India from Yemen about the 6th century. They abstain from unclean fish and flesh, keep the great feasts, and have always strictly observed the Sabbath, while they have a distinctly Jewish cast of countenance. Their number is about 5000, mostly artisans, though some are soldiers. They claim to have existed for about a thousand years, and assert that they assumed the name by which they are known because that of Jehudim ('Jews') was hateful to the Mussulmans. Some of them know Hebrew, but Marathi is their ordinary language, and in it they possess some literature. They rarely intermarry with the ordinary Jews. Among them there exists a class, called Kala Israel ('Black Israel'), with which they never intermarry, as the latter are socially much inferior, being either their own descendants by heathen wives, or the offspring of proselytes. A similar distinction exists among the Jews of Cochín. In Bombay an official called *Nassi*, or head, dispenses justice among the Beni-Israel, while the principal authorities in religious matters are the *kayees*; but in the outlying villages these dispose of both ecclesiastical and civil business, with the aid of a council. It should be remembered that the Afghans call themselves Bani-Israel, and claim descent from King Saul.

Benin, a country of Western Africa, lying between the lower Niger and Dahomey. Benin was formerly one of the most powerful kingdoms in West Africa, but it was subsequently broken up into several small states; and now it is all included in the British protectorate of Nigeria—for the most part in the Benin district of the same (organised 1897). The soil is very fertile, producing rice, yams, palms, pepper, plantains, cotton, sugar, &c. The population is dense. The government, customs, and superstitions of Benin are like those of Ashanti. The capital, Benin, is 73 miles inland from the mouth of the Benin River, and has a population of above 15,000. Gato, a harbour lower down the river, is an important centre for the palm-oil trade. Wari or Jaku, 130 miles SE. of Benin, is on an island surrounded by a branch of the Niger. The river Benin is 2 miles wide at its mouth, but has a troublesome bar of mud. Benin was discovered by the Portuguese Alfonso de Aveiro (1486), and a large trade in slaves was carried on. The French Bight of Benin settlements (Porto Novo, Kolonu or Cotonou, Grand Popo, and Agoué) are on the coast of Dahomey.

Benin, BIGHT OF, that portion of the Gulf of Guinea (q.v.) extending from Cape Formosa on the E. to Cape St Paul on the W., a distance of about 390 miles, with a coast-line of 460 miles. Several rivers empty themselves into the Bight of Benin, three of which are accessible to shipping. Palm-oil and ivory are the principal articles of trade at the towns on the coast.

Beni-Suef, a town of central Egypt, capital of a province of the same name, on the right bank of the Nile, about 70 miles SSW. of Cairo. A branch line of railway has been constructed westward to Medinet el Fayum, and the town is the entrepôt of all the produce of the fertile valley of Fayum, and has cotton-mills and alabaster quarries. The population of the province is about 453,000; of the town, 32,000.

Bénitier, the vase or vessel for Holy Water (q.v.) in Roman Catholic churches, known in England as the holy-water font, vat, pot, stone, stock, or stoup. Bénitiers are either movable or fixed; portable ones, commonly of silver, being used in processions; and fixed bénitiers placed near the doors of churches, so that the people may dip their fingers in the water, and cross themselves with it as they enter or leave the church.

Benjamin ('son of the right hand'), the youngest and most beloved of the sons of Jacob. His mother, Rachel, died at his birth, naming the child with her last breath *Benoni* ('son of my pain'), but his father changed this ill-omened name to Benjamin. He was the eponymous founder of one of the twelve tribes of Israel. Its warriors were noted for their skill in archery, and for their cleverness in the use of the left hand. According to the Scripture numeration, the tribe in the desert numbered 35,400 warriors above twenty years of age; and on the entrance into Canaan, 45,600. Its territory, which was small but fertile, lay on the west side of the Jordan, between the tribes of Ephraim and Judah. The chief places were Jericho, Bethel, Gibeon, Gilgal, and Jerusalem, the last of which was on the confines of Judah. In the time of 'the Judges,' the tribe of Benjamin became involved in a war of extermination with the eleven other tribes of Israel, who put to death all the males save 600, who afterwards procured themselves wives by a kind of Sabine rape. Saul, the first king of Israel, was of the tribe of Benjamin, which remained loyal to his son, Ishbosheth. After the death of Solomon, Benjamin along with Judah formed the kingdom of Judah; and on the return from the captivity these two constituted the principal element of the new Jewish nation. The apostle Paul was a Benjamite.

Benjamin OF TUDE'LA, a Jewish rabbi, was born in Navarre, Spain. He was the first European traveller who gave information respecting the distant East. Partly with commercial views, and partly to inquire into the condition of his dispersed co-religionists, he made a journey, in the years 1159-73, from Saragossa, through Italy and Greece, to Palestine, Persia, and the borders of China, returning by way of Egypt and Sicily. He died in 1173. His itinerary—written in Hebrew, and frequently republished in Latin, English, Dutch, German, and French translations—is occasionally concise and valuable; but, like all early travellers, Benjamin had a greedy ear for the marvellous. His blunders, too, are numerous.

Benjamin, JUDAH PHILIP (1811-84), born at St Croix, West Indies, was the son of Anglo-Jewish parents, who emigrated to the United States, where he practised as a lawyer in New Orleans. He was engaged prominently in politics, serving first with the Whigs, and afterwards with the Democrats. He sat in the United States senate

from 1852 till Louisiana's secession in 1860, and in February 1861 joined Jefferson Davis's cabinet as Attorney-general. He was for a few months Secretary of War, and then acted as Secretary of State until Davis's capture in 1865, when he escaped with some difficulty to England. He was called to the English bar in the following year, became a Q.C. in 1872, and retired from a large practice in 1881. He wrote a *Treatise on the Law of Sale of Personal Property*.

Benjamin Tree. See BENZOIN.

Benkulen. See BENCOELEN.

Ben Lawers, a Perthshire mountain, flanking the NW. shore of Loch Tay. Easy of ascent, it is rich in alpine plants, and there is a magnificent view from its summit, which is 3984 feet high, or with the cairn (rebuilt in 1878), 4004.

Ben Led'i, a mountain (2875 feet) of Perthshire, $4\frac{1}{2}$ miles W. by N. of Callander. A jubilee cairn was erected on it in 1887.

Ben Lo'mond, a Scottish mountain in the NW. of Stirlingshire, on the east side of Loch Lomond, $18\frac{1}{2}$ miles N. of Dumbarton. It is 3192 feet high, and consists of mica slate, with veins of quartz, greenstone, and felspar porphyry. The summit is precipitous on the north side, with a gentle declivity on the south-east; it is covered with vegetation to the top. Seen from Loch Lomond, it appears a truncated cone, and from between Stirling and Aberfoyle a regular pyramid. The magnificent view from the top in clear weather includes the whole length of Loch Lomond, with its diversified isles, and wooded and cultivated shores, the rich plains of Stirlingshire and the Lothians, the windings of the Forth, the castles of Stirling and Edinburgh, the heights of Lanarkshire, the vales of Renfrewshire and Ayrshire, the Firth of Clyde, the Isles of Arran and Bute, the Irish coast, Kintyre, and the Atlantic. The north semicircle of the horizon is bounded by Ben Lawers, Ben Voirlich, Ben Ledi, Ben Cruachan, and Ben Nevis, and some of the Perthshire lochs are seen.

Benlowes, EDWARD, poet, born about 1603, studied at St John's College, Cambridge, travelled on the Continent, inherited Brent Hall, Essex, spent his fortune on poets and scholars, and died in poverty at Oxford in 1676. By conversion or upbringing a Roman Catholic, he became an Anglican in later life. His principal work, *Theophilus, or Love's Sacrifice* (1652), is 'a very discursive treatise on mystical theology and passions of the soul, followed by an equally discursive comment on the sins of the flesh.' The poem was lavishly illustrated by plates and vignettes, and 'several parts thereof set to fit airs by Mr J. Jenkins.' Partly in Latin, mostly in English, it is written in an awkward stanza, and exhibits the extravagances of 'metaphysical' conceit in their extremest form. See Saintsbury's *Caroline Poets* (vol. i. 1905), and Butler's *Character of a Small Poet*.

Ben Macdhu'i, a mountain (4296 feet) of south-west Aberdeenshire, 18 miles WNW. of Castletown-of-Braemar. One of the Cairngorms, it is not a conspicuous summit, but was formerly thought to be higher than Ben Nevis, which alone in Scotland outtops it.

Bennett, (ENOCH) ARNOLD, was born in 1867 in the district of Shelton, north-east of Hanley, one of 'The Five Towns' in north Staffordshire, scene of many of his best works. Abandoning law for literature by way of journalism, he revealed from the close of the 19th century remarkable versatility in a series of works ranging from short stories to a lengthy trilogy; from breathless extravaganzas to grim, slow-moving novels à la Flaubert and the

realists; from comedies rippling with laughter and spiced with satire to Biblical drama—not to mention essays in *belles lettres* largely of a journalistic character. Mr Bennett courted and won popularity in his sensational stories and fantasias—such as *The Grand Babylon Hotel* (1902), *The Gates of Wrath*, and *Buried Alive* (1908; dramatised in 1911 with striking success as *The Great Adventure*). This popularity was confirmed by the breezy humour of *The Card* (1911) and other stories depicting the lighter side of life in the Potteries district, and by the comedy *What the Public Wants* (1909), with its biting satire on the catchpenny press. But it is to his realistic novels that Mr Bennett owes his enduring place in literature—to *Riceyman Steps* (1923), to the drab, yet penetrating, pictures of 'The Five Towns' in *The Old Wives' Tale* (1908), *Clayhanger* (1910), and its sequels *Hilda Lessways* (1911) and *These Twain* (1916); and to the artfully objective *The Pretty Lady* (1918). Much autobiographical material is contained in his *The Truth about an Author* (1903; revised edition, 1914) and other treatises on life and literature.

Bennett, JAMES GORDON (1795–1872), born near Keith, in Banffshire, and trained for the Roman Catholic priesthood, emigrated to America in 1819, where he became in turn teacher, proof-reader, journalist, and lecturer. On 5th May 1835 he issued the first number of the *New York Herald* as an independent newspaper, and laid the foundation of its enormous success.—His son, JAMES GORDON BENNETT (1841–1918), showed like enterprise in the conduct of the *Herald*. He sent Stanley (q.v.) in 1870 to find Livingstone, and, with the *Daily Telegraph*, financed his Congo journey (1874–78). He supported polar exploration, storm warnings, and automobilism.

Bennett, JOHN HUGHES, an eminent physician, born in London, 31st August 1812, graduated at Edinburgh in 1837, and after four years' study in Paris and Germany, settled in Edinburgh as an extra-mural lecturer. A work published in 1841, in which he recommended cod-liver oil in all consumptive diseases, first brought him into notice, and in 1848 he was made professor of the Institutes of Medicine in Edinburgh University—a post which he held until 1874. His health gave way in 1871, and most of his last years were spent abroad. He died at Norwich, 25th September 1875. His original investigations are embodied in numerous treatises and articles in medical journals, and in his *Text-book of Physiology* (Edin. 1870–71).

Bennett, WILLIAM, born in 1804, graduated B.A. at Oxford in 1837, and, taking orders, was incumbent of Portman Chapel, and of St Paul's, Knightsbridge. The latter charge he resigned in 1851, in consequence of an anti-Tractarian outcry; but he was almost immediately presented to the vicarage of Frome in Somersetshire. An extreme High Churchman, he was author of many theological works, but is chiefly remembered through the case of *Sheppard v. Bennett* (1870–72), wherein his teaching on the Real Presence was pronounced to be not inconsistent with the doctrine of the Church of England. He died 15th August 1886.

Bennett, SIR WILLIAM STERNDALÉ, Mus.D., D.C.L., English pianist and composer, was born at Sheffield, 13th April 1816. After studying for ten years at the Royal Academy, London, he was sent to complete his musical education at Leipzig. He attracted the notice of Mendelssohn at the Düsseldorf Musical Festival, appeared with success at Leipzig in the winter of 1837–38, and was received with great applause when he returned to London. In 1838 he was elected member of the Royal Society of Music, and in 1856 became professor of Music at Cambridge. At the opening of the International

Exhibition, 1862, Tennyson's ode, *Uplift a Thousand Voices*, was sung to music by Bennett. In 1868 he became principal of the Royal Academy of Music, and was knighted in 1871. He died 1st February 1875, and was buried in Westminster Abbey. His published compositions include a symphony, four concert overtures, the two cantatas *The May Queen* and *The Woman of Samaria*, and a few songs. But his peculiar individuality is best exemplified in his works for the pianoforte, of whose capabilities he was a great master; of these, the principal are four concertos and a capriccio with orchestra, two sonatas, and numerous studies. His music is characterised by graceful fancy and delicate finish in the minutest details, rather than commanding power or depth of feeling. His earlier works resemble Mendelssohn's, but a better parallel for the genius of his music generally has been pointed out in Scarlatti, his favourite master in pianoforte music. In his later years his creative activity was almost sunk in that of the teacher. Cordially recognised by Mendelssohn and Schumann, he remained till lately almost the sole representative of English music at all widely known on the Continent. See the Life by his son (1908).

Ben Nevis, a mountain of Inverness-shire, 7 miles SE. of Fort William, by a carriage-road opened in 1880. The loftiest summit in Great Britain, it has a height of 4406 feet, with a tremendous precipice of 1500 feet on the north-east side. Granite and gneiss form the base of the mountain, which above is composed of porphyry. A meteorological observatory was erected on the summit in 1882, and constant observations were made and communicated by telegraph; but both this and the associated low-level observatory in Fort William (opened in 1890) were closed in 1904 for want of adequate support.

Bennigsen, LEVIN AUGUST THEOPHIL, COUNT, a general in the Russian service, was born at Brunswick in 1745, and having entered the Russian service in 1773, soon attracted the notice of the Empress Catherine, who employed him to carry out her designs against Poland. He fought at Pultusk (1806), and held the chief command in the murderous struggle at Eylau (1807). When Napoleon invaded Russia in 1812, Bennigsen commanded the Russian centre on the bloody field of Borodino. Before the French began their retreat, he gained a brilliant victory over Murat at Tarutino (October 18). Differences with Kutusov made him retire for a time from the service; but after that general's death, he took the command of the Russian army of reserve, fought victoriously at the battle of Leipzig, and was created count by the Emperor Alexander on the field. Failing health made him retire finally, in 1818, to his paternal estate in Hanover, where he died in 1826.

Bennington, a town of Vermont, 37 miles NE. of Troy, N.Y., has woollen and iron manufactures. It was the scene of an American victory in 1777. Pop. 10,000.

Benoît de Sainte-More, French trouvère of the latter half of the 12th century, wrote a lengthy *Roman de Troie* (ed. L. Constans, 1906 *et seq.*), and probably (for Henry II. of England) a *Chronique des Ducs de Normandie*. Other romances have been doubtfully assigned to him.

Benoni, a gold-mining town of the Transvaal, 20 miles E. of Johannesburg; pop. 47,500 (14,500 white).

Benshie. See BANSHEE.

Benson, EDWARD WHITE (1829–96), Archbishop of Canterbury, born near Birmingham, took a first at Cambridge, senior optime, was a master at Rugby, and first head-master of Wellington

College. In 1876 he was nominated to the newly erected bishopric of Truro, and in 1882 was translated to Canterbury. He published several volumes of sermons, and works on Cathedrals and on St Cyprian, and gave the important judgment in the Lincoln case on ritual. See the Life by his eldest son, A. C. BENSON (1862-1925), Master of Magdalene College, who published poems, essays, book on Laud, Tennyson, Rossetti, FitzGerald, Pater, and Ruskin, and on his brother Hugh, and (with Lord Esher) edited Queen Victoria's correspondence, 1907. The article on Matthew Arnold in this work is from his pen. His third son, EDWARD FREDERIC (b. 1867), is author of *Dodo* (1893), *The Rubicon*, *The Babe B.A.*, *Vintage*, *The Angel of Pain*, and many other novels and plays. A younger son, ROBERT HUGH (1871-1914), became a Roman Catholic priest, a popular preacher, and private chamberlain to Pope Pius X. He wrote *The Light Invisible* and other novels, and some theological works. See Life by Martindale (1916).

Benson, RICHARD MEUX (1824-1915), founder and first Superior (1866-1890) of the Society of Mission Priests of St John the Evangelist, commonly called the Cowley Fathers. He studied at Oxford, was vicar of Cowley in 1850-70, and of Cowley St John (then separated) in 1870-86. He wrote sermons and devotional books. See his *Letters* (1916-20). The Cowley Fathers are an Anglican monastic society 'for the cultivation of a life dedicated to God according to the principles of poverty, chastity, and obedience.' Its headquarters are at Cowley St John, near Oxford. The fathers, who are employed in educational and missionary work, wear a black cassock with a black cord and a long black cloak.

Bent Grass (*Agrostis*), a genus containing about a hundred species (see GRASSES, PASTURE).—Common Bent Grass (*A. vulgaris*), abounding on dry elevated lands, becomes a pest in arable land. *A. canina* is also common.—Marsh Bent Grass (*A. alba*) is found in moist situations, and a variety (*A. stolonifera*) is known as Fiorin Grass. *A. dispar*, American Herd Grass, or Red Top Grass, is cultivated in France. The rarer and more delicate *A. spica-venti* is chiefly admired for its graceful appearance. Most of the European species are North American also. In the United States and Canada some of the bents are highly important as pasture and forage plants. On suitable soils *A. vulgaris* and *alba* give excellent crops of hay.

Bentham, GEORGE, botanist, nephew of the jurist, was born in 1800 at Stoke, a village since absorbed in Portsmouth. The son of an officer who had risen to high rank in both the Russian and English services, young Bentham's earlier years were spent largely abroad, but from 1826 to 1832 he lived with his uncle, to whom he acted as secretary while carrying on his own legal studies. His *Outlines of a New System of Logic* (1827) is a remarkable book; herein for the first time is clearly set forth the doctrine of the quantification of the predicate, in which he thus anticipated Sir William Hamilton. Only sixty copies, however, were sold when the publishers became bankrupt; and the fact that the work contained this discovery was not recognised until 1850, although Bentham's claims have been fully vindicated since. Though called to the bar, he soon abandoned the law for botany. He had catalogued the plants of the Pyrenees (1824-26), and had been elected in 1828 a Fellow of the Linnæan Society, and in 1829 secretary of the Horticultural Society. He now devoted himself to his new study, and soon published his important *Labiatularum Genera et Species* (1832-36). In 1854 he presented his collections to the Royal Gardens at Kew, where for the rest of

his life he was engaged almost every day in his task of systematisation and description. He there elaborated the flora of Hong-Kong and of Australia, and in conjunction with Sir Joseph Hooker, completed his exhaustive and valuable *Genera Plantarum* (3 vols. 1862-83), which may be said to summarise the botany of flowering plants. His numerous other writings did much to elucidate the flora of almost every region outside the Arctic circle. He died 10th September 1884. From 1863 to 1874 president of the Linnæan Society, Bentham was a member of many other British and foreign learned bodies, and in 1878, on the completion of the Australian flora, received a Companionship of St Michael and St George. See a book on him by B. D. Jackson (1906).

Bentham, JEREMY, writer on jurisprudence and ethics, was the son of a pushing attorney in London, where he was born (in Red Lion Street, Houndsditch) on 15th February 1748. At the age of seven he was sent to Westminster School; and in 1760, being only twelve years old, he entered Queen's College, Oxford, where he took his B.A. degree in 1763. But though his years were so tender, he appears to have been less unprepared than might be supposed to benefit by the university; for before entering it, he had already, by his precocious tendency to speculation, acquired the title of 'the philosopher.' His father, who expected him to become Lord Chancellor, set him to study law at Lincoln's Inn, where he was called to the bar in 1772. He never practised, however, having a strong distaste for his profession, which is paraded in many of his writings. Turning from the practice of law to its theory, he became the greatest critic of legislation and government in his day. His first publication, *A Fragment on Government* (1776), was an acutely precritical examination of a passage in Blackstone's *Commentaries*, prompted, as he has himself explained, by 'a passion for improvement in those shapes in which the lot of mankind is meliorated by it.' The *Fragment* abounds in fine, original, and just observation; it contains the germs of most of his after writings, and must be highly esteemed, if we look away from its disproportion to its subject and the writer's disregard of method. It procured him, in 1781, the acquaintance of Lord Shelburne (Lansdowne), at whose seat, Bowood, he afterwards passed perhaps the most agreeable hours of his life. Here it was that he met Miss Caroline Fox (Lord Holland's sister), who was still a young lady, when Bentham, in 1805, offered her his heart and hand, and was rejected 'with all respect.'

On the death of his father in 1792, he succeeded to property in London, and to farms in Essex, yielding from £500 to £600 a year. He lived frugally, but with elegance, in Queen Square, Westminster; and employing young men as secretaries, got through an immense amount of work and correspondence. By a life of temperance and great self-compacency, in the society of a few devoted friends ('who,' says Sir James Mackintosh, 'more resembled the hearers of an Athenian philosopher than the proselytes of a modern writer'), he attained the age of eighty-four, dying 6th June 1832. In accordance with his own directions, his body was dissected; and his skeleton, dressed in his accustomed garb, is preserved at University College, London.

A pamphlet on *The Hard Labour Bill* (1778), recommending an improvement in the mode of criminal punishment, was an excerpt from his *Rationale of Punishments and Rewards* (1825), which was written in 1775, but first saw the light in a French translation by Dumont (1811). In these two works, Bentham did more than any other writer of his time to rationalise the theory

of punishments by consideration of their various kinds and effects, their true objects, and the conditions of their efficiency. He published in 1787 *Defence of Usury*; in 1789, *Introduction to the Principles of Morals and Legislation*; in 1802, *Discourses on Civil and Penal Legislation*; in 1813, *A Treatise on Judicial Evidence*; in 1817, *Paper relative to Codification and Public Instruction*; in 1824, *The Book of Fallacies*. His works were collected and edited in 1843 by Bowring and John Hill Burton, in 11 volumes. It is well, however, for Bentham's reputation, that it does not rest wholly on his published writings; and that he found in Dumont, the Mills, and Sir Samuel Romilly, generous disciples to diffuse his principles and promote his fame. In his early works, his style was clear, free, spirited, and often eloquent; but, from 1810, it became overloaded and darkened with technical terms. It is in regard to these more especially that M. Dumont has most materially served his master by arranging and translating them into French, through the medium of which language Bentham's doctrines were propagated throughout Europe, till they became more popular abroad than at home. James Mill, himself an independent thinker, did much in his writings to extend the application in new directions of Bentham's principles, a work in which, apart from his original efforts, he achieved a lasting monument of his own subtlety and vigour of mind.

In all Bentham's ethical and political writings, the doctrine of utility is the leading and pervading principle. His favourite vehicle for its expression, 'the greatest happiness of the greatest number,' a phrase first formulated by Hutcheson and taken over by Beccaria and Priestley, owes its currency to Bentham. 'In this phrase,' he says, 'I saw delineated for the first time a plain as well as a true standard for whatever is right or wrong, useful, useless, or mischievous, in human conduct, whether in the field of morals or politics.' In the application of the principle Bentham arrived at various conclusions, which he advocated irrespective of the conditions of society in his day, and of the laws of social growth, which, indeed, neither he nor his contemporaries understood. He demanded nothing less than the immediate remodelling of the government, and the codification and reconstruction of the laws; and insisted, among other changes, on universal suffrage, annual parliaments, vote by ballot, and paid representatives. Many of his schemes have been realised, many more are in course of realisation; the end and object of them all was the general welfare, and his chief error lay in conceiving that organic changes are possible through any other process than that of growth and modification of popular needs, ideas, and institutions. It was this error that led the philosopher, in his closet in London, to devise codes of laws for Russia (through which country he made a tour in 1785) and America, the adoption of which would have been equivalent to revolutions in these countries, and then bitterly to bewail the folly of mankind when his schemes were rejected. But in Mill's words, 'he found the philosophy of law a chaos, and left it a science.' He may be regarded as the philosophic pioneer of Liberalism and Radicalism, and holds a high place in the history of political thought.

See J. H. Burton's *Benthamiana* (1843), the Life in Bowring's edition of his works, that by C. M. Atkinson (1905), and the articles MILL (J. S.), UTILITARIANISM, &c.

Benthamia, a sub-genus of *Cornaceæ* (q.v.) in which the many small drupes grow together. *Benthamia fragifera*, a native of Nepal, is a small tree, with lanceolate leaves, fragrant flowers, and a reddish fruit, not unlike a mulberry, but larger; not unpleasant to the taste. Its fruit has been known to ripen in the south of England.

Bentinck, WILLIAM, first Earl of Portland, born in Holland in 1649, was the descendant of a noble family which in the 14th century had migrated from the Palatinate to Gelderland, where it is still represented by a younger line. He was from boyhood the favourite and friend of William III., and was founder of the fortune of the Bentinck family in England. He was constantly employed, both in military and diplomatic services, and trusted beyond all others with the secrets of the king's foreign policy. After the coronation of William and Mary, Bentinck was created an English peer, and presented with large estates and numerous offices in the royal household; but these last he resigned in 1699, from jealousy of Arnold van Keppel, Earl of Albemarle. The king's affection, however, never wavered to the end of his life. Bentinck died in 1709. See Mrs M. E. Grew, *William Bentinck and William III.* (1924).—WILLIAM CAVENDISH BENTINCK, third Duke of Portland, born in 1738, entered Lord Rockingham's cabinet in 1765, and succeeded him as leader of the Whig party. He was twice prime-minister—April to December 1783, and 1807-9; but his best work was done as Home Secretary under Pitt, with charge of Irish affairs, throughout the eventful period 1794-1801. He died a month after resigning the premiership, November 30, 1809.—LORD WILLIAM CAVENDISH BENTINCK, Indian statesman, second son of the third Duke of Portland, was born in 1774, and became an ensign in the Coldstream Guards in 1791. Having served with distinction in Flanders and Italy, he was governor of Madras (1803-7), where he advocated several useful reforms; but his prescription of sepoy beards and turbans led to the massacre of Vellore, and his own immediate recall. From 1808 to 1814 he was serving in the Peninsula and Italy; in 1827 he was appointed governor-general of Bengal, and in 1833 became the first governor-general of India. His policy in India was pacific and popular, and his viceroyship was marked by the suppression of suttee and thuggism, the educating and employment of natives, the opening up of the internal communication, and the establishment of the overland route. He returned to England in 1835, and died at Paris, June 17, 1839. See a Life by Boulger (1892).

LORD GEORGE BENTINCK, sportsman and leader of the Protectionists, the third son of the fourth Duke of Portland, was born 27th February 1802, and, entering the army in 1819, attained six years afterwards the rank of major. From 1822 to 1825 he was private secretary to his uncle, Mr Canning, and in 1826 was elected member for Lynn-Regis. At first, attached to no party, he voted for Catholic emancipation and for the principle of the Reform Bill, but against several of its most important details, and in favour of the celebrated Chandos clause. On the formation of Peel's ministry in December 1834, he and his friend Lord Stanley, afterwards Earl of Derby, with some adherents, formed a separate section in the House of Commons; but, on Peel's resignation in the following April, Lord George openly joined the Conservative party, and in 1841 received from Peel an offer of office, which he declined, being at that time too deeply engrossed in racing and field-sports. When Peel introduced his free-trade measures in 1845, a large body of his supporters formed a Protection party, Lord George assuming its leadership, and taking henceforth a prominent part in the debates. A hard hitter, and a master of figures, he was no orator; yet his speeches in the session of 1846 were most damaging to the government of Sir Robert Peel, and contributed in no small degree to hasten its downfall. He was always a champion of religious liberty, advocating the removal of the Jewish disabilities, and the endowment of the Irish Catholic

clergy out of the land; and at the time of the potato famine he wanted government to lend £16,000,000 for reproductive works in Ireland. He was an 'Admirable Crichton' of field-sports, and though he never did win the Derby, had brilliant success on the turf, whose dishonest practices he showed the utmost zeal to suppress. He died suddenly, 21st September 1848, whilst walking near Welbeck Abbey. See his *Life* by Lord Beaconsfield (1851), and his *Racing Life* by Kent (1892).

Bentley, RICHARD, scholar, was born of yeoman parentage at Oulton, in the West Riding of Yorkshire, January 27, 1662. After four years at Wakefield grammar-school, he entered St John's College, Cambridge, in 1676, as subsizar. Little is known of his university career, except that he showed early a strong taste for the cultivation of ancient learning. At the usual time, he took the degree of Bachelor of Arts; and in 1682 he was appointed by his college to the head-mastership of Spalding grammar-school, in Lincolnshire. Within the year he resigned this situation to become tutor to the son of Dr Stillingfleet, then Dean of St Paul's, and subsequently Bishop of Worcester. In 1689 he accompanied his pupil to Oxford, where he had full scope for the cultivation of classical studies; and that he succeeded in acquiring there some local reputation is evinced by his having been twice appointed to deliver the Boyle Lectures on the Evidences of Natural and Revealed Religion. He had taken orders in 1690, and to Stillingfleet he owed various good ecclesiastical preferments, with the post of librarian of the King's library at St James's. His *Letter to Mill* (1691) on the chronicler John Malelas is itself a masterpiece; but it was the *Dissertation upon the Epistles of Phalaris* (1699), an expansion of an earlier essay, that established his reputation throughout Europe, and may be said to have commenced a new era in scholarship. The principles of historical criticism were then unknown, and their first application to establish that the so-called Epistles of Phalaris (q.v.), which professed to have been written in the 6th century B.C., were the forgery of a period some eight centuries later, filled the learned world with astonishment.

In 1700 Bentley was appointed Master of Trinity College, Cambridge; and in the following year he married Joanna Bernard, the daughter of a Huntingdonshire knight. The history of Bentley's Mastership of Trinity is the narrative of an unbroken series of quarrels and litigations, provoked by his arrogance and rapacity, for which, it must be confessed, he was fully as well known during his lifetime as for his learning. He contrived, nevertheless, in 1717, to get himself appointed regius professor of Divinity, and, by his boldness and perseverance, managed to pass scathless through all his controversies. Notwithstanding that in 1714 one Bishop of Ely, the visitor of Trinity, was hindered only by death from pronouncing sentence depriving him of his mastership, that in 1718 the university senate deprived him of his degrees, and that in 1734 another bishop did actually pronounce his deposition, he was in full possession of both mastership and degrees at the time of his death. This stormy life did not impair his literary activity. He edited various classics—among others, Horace (1711) and Terence (1726)—upon which he bestowed vast labour. Emendations were at once his forte and foible—the latter conspicuously in his edition of *Paradise Lost* (1732). He is, perhaps, more celebrated for what he proposed than for what he actually performed. The proposal (1720) to print an edition of the Greek New Testament, in which the received text should be corrected by a careful comparison with the Vulgate and all the oldest

existing Greek MSS., was then singularly bold, and evoked violent opposition. He failed in carrying out his proposal; but the principles of criticism which he maintained have since been triumphantly established, and have led to important results in other hands, as in Lachmann's. He is to be regarded as the founder of that school of classical criticism of which Porson afterwards exhibited the chief excellences as well as the chief defects; and which, though it was itself prevented by too strict attention to minute verbal detail from ever achieving much, yet diligently collected many of the facts which men of wider views are still grouping together to form the modern science of comparative philology. Bentley died 14th July 1742, leaving behind him one son, Richard, who inherited much of his father's taste with none of his energy, and two daughters, one of whom, Joanna, married, and was the mother of Richard Cumberland the dramatist. See Monk's *Life of Bentley* (2 vols. 1833); Jebb's *Bentley* (1882); and Dyce's unfinished edition of his works (3 vols. 1836-38).

Benton, THOMAS HART, an American statesman, born in North Carolina in 1782, settled in Tennessee, where he studied law, and was elected to the legislature. In 1812 he raised a regiment of volunteers, and also served on General Jackson's staff. After the war, he started a newspaper in St Louis, by which he became involved in several duels. On the admission of Missouri as a state, he was chosen United States senator in 1820, and in this post, during thirty years' continuous service, took a leading part in public affairs. He died in Washington, April 10, 1858. A determined opponent of Calhoun's nullification scheme, he afterwards supported Jackson in his war on the United States bank, and earned the sobriquet of 'Old Bullion' by his opposition to the paper currency. He published *A Thirty Years' View, or a History of the Working of the American Government from 1820 to 1850* (2 vols. 1854-56); and *An Abridgment of the Debates of Congress from 1789 to 1856* (15 vols. 1857).

Benué (spelt also *Binue* and, by Dr Barth, *Benuwé*), an important river of Central Africa, forming the great eastern affluent of the Niger, which it joins about 230 miles above the mouth of that river in the Gulf of Guinea. Dr Barth describes the Benué as being 800 yards across, with a general depth in its channel of 11 feet, and 'a liability to rise under ordinary circumstances at least 30 feet, or even at times 50 feet higher.' In 1854 an expedition under the command of Dr Baikie explored it as far as Dulti, a place about 350 miles above its confluence with the Niger. In a second expedition, undertaken in 1862, Dr Baikie explored as far north as Kano, in Hausa. The Church Missionary Society sent out an exploring party in 1879 under Flegel, who in 1883 reached its sources in Adamawa; and Mizon's expedition in 1892 greatly extended our knowledge of it. Flowing through wide tracts of fertile territory, and navigable for 700 miles, the Benué is a highway into the heart of the Sudan, and is evidently destined to be an important channel of commerce with Central Africa.

Benyowsky, MAURICE AUGUSTUS, COUNT DE, a remarkable Hungarian adventurer, born in 1741. While fighting for the Polish Confederation, he was taken prisoner in 1769, and banished to Kamchatka, where he was made tutor in the family of the governor. In this capacity he gained the affections of the daughter of the governor, by whom he was assisted in his plans for escape; which, however, was not effected without a struggle, in which the governor was killed. Benyowsky, with ninety-six companions, set sail in a ship well armed and provisioned, and with a considerable amount of

treasure, and reached France in 1772. Invited by the French government to found a colony at Madagascar, he arrived on the island in February 1774, and was made king in 1776 by the chiefs in conclave, he adopting the native costume. His relations with the French were now not always friendly, and while in contention with the government of Mauritius, he was killed in battle, May 23, 1786. See *Memoirs and Travels of Benyowsky, written by Himself* (1790; new ed. by Pasfield Oliver, 1904).

Benzene, a compound of carbon and hydrogen, C_6H_6 , discovered by Faraday in 1825, in a tarry liquid resulting from the distillation of oil. It must not be confounded with Benzine or Benzoyl, which names have at different times been used for benzene. *Benzine* is the name given to a distillate from American petroleum, which is much used as a substitute for turpentine, and for dissolving oils and fats. *Benzoyl* is the commercial name applied to a mixture of substances, including benzene and its homologues. *Benzol* is synonymous with benzene, while *benzoline* is a name applied to benzene and impure benzene indiscriminately. Benzene is found amongst the products of the destructive distillation of a great many organic bodies. The most abundant source of benzene is coal-tar (see GAS, COAL). On distilling coal-tar, the more volatile liquid hydrocarbons pass over first, mixed with acid and basic compounds, and constitute what is known as light oil or coal naphtha. When the crude naphtha is purified by redistillation and subsequent agitation, first with sulphuric acid, and then with caustic soda, an oil is obtained which consists mainly of benzene and its homologues. By submitting this oil to a process of fractional distillation, a portion is obtained, boiling at 176° – 212° (80° C.– 100° C.), from which benzene crystallises out on cooling the liquid to 32° (0° C.). The benzene is freed by pressure from the substances remaining liquid at this temperature. Commercial benzene is, however, always impure. Pure benzene is most readily obtained by cautiously distilling a mixture of one part benzoic acid with three parts of slaked lime. The mixture of benzene and water which passes over is shaken up with a little potash, the benzene decanted, treated with calcium chloride to take up the water, and the dried benzene thus obtained is rectified on the water-bath. At ordinary temperatures benzene is a thin, limpid, colourless liquid, evolving a characteristic and pleasant odour. At 41° F. (5° C.) it solidifies; and at 176° F. (80° C.) it boils, evolving a gas which is very inflammable, burning with a smoky flame. It readily dissolves in alcohol, ether, turpentine, and wood-spirit, but is insoluble in water. It is valuable to the chemist from the great power it possesses of dissolving rubber, gutta-percha, wax, camphor, and fatty substances. Impure benzene is thus much used in removing grease-stains from woollen or silken articles of clothing. When heated, benzene also dissolves sulphur, phosphorus, and iodine. Commercially of importance, benzene is from the chemical point of view a compound of surpassing interest. It consists of 12 parts of carbon by weight, with 1 part of hydrogen, and might therefore be represented by the formula CH ; but it has been found that the molecule weighs six times as much as this, and requires the formula C_6H_6 . Benzene has been synthesised by Berthelot by heating acetylene in a closed retort. This is known as polymerisation.

The manner in which the atoms are arranged in the molecule has already been referred to in the article on the Aromatic Series, and it will be seen by a reference to the graphic formula there given that the number of compounds derivable from benzene

is practically unlimited. The so-called coal-tar colours are all derivatives of benzene (see the article ANILINE).

Benzerta. See BIZERTA.

Benzoic Acid, or the *Flowers of Benzoïn*, has been known since the beginning of the 17th century, and occurs naturally in many balsamiferous plants, and especially in benzoïn gum, from which it may be readily obtained by several processes. The simplest is as follows: The coarsely powdered resin is gently heated in a shallow iron pot, the mouth of which is closed by a diaphragm of coarse filter-paper. Over this is tied a covering of thick paper somewhat like a hat. The porous filter-paper allows the vapours of benzoic acid to pass through it, but keeps back the empyreumatic products. At the end of the operation, the hat-like cover is found lined with a crystalline sublimate of benzoic acid which is nearly pure, being mixed only with traces of a volatile oil, which gives it a pleasant smell, like vanilla. The benzoic acid thus prepared is the best for pharmaceutical purposes. Benzoic acid is also prepared from the urine of graminivorous animals, but has a slight urinous odour. The acid is manufactured cheaply by synthetic methods, toluene or naphthalene being used as starting-point. The acid obtained from the latter is frequently resublimed with benzoïn to give it a vanilla-like odour. Benzoic acid is always in the form of snow-white, glistening, feathery crystals, with a fairy aspect of lightness, having a warm, acid, acidulous taste. It is readily dissolved by alcohol and ether, but sparingly soluble in water, which, however, dissolves it readily on the addition of borax or phosphate of soda. It is one of the materials present in *Tinctura Camphoræ Composita*, and has been administered in chronic bronchial affections, its value being due to its locally stimulating properties. It has also been used largely in genito-urinary diseases. Benzoic acid taken into the stomach increases within three or four hours the quantity of hippuric acid in the urine. Benzoic acid and the benzoates are much used in antiseptic preparations. The chemical formula for crystallised benzoic acid is C_6H_5COOH . Oil of bitter almonds is the aldehyde of benzoic acid (see ALDEHYDES), and the corresponding alcohol, benzoic or benzylic alcohol, is also known.

Benzoin, BENJAMIN, or BENZOIC GUM, a fragrant resinous substance, formed by the drying of the milky juice of the Benzoïn or Benjamin Tree (*Styrax*, or *Lithocarpus benzoïn*), a tree of the natural order Styracaceæ, and a congener of that which produces Storax (q.v.), a native of Siam, and of Sumatra and other islands of the Indian Archipelago. Benzoin is first mentioned by Batuta in 1350 A.D. as Java Frankincense (Arabic *Lubān Jāwī*), corrupted into Banjawi, Benjoin, Benzoe, &c. Benzoin comes to us in reddish-yellow transparent pieces. Different varieties, said to depend upon the age of the trees, are of very different price; the whitest, said to be the produce of the youngest trees, being the best. Amygdaloidal benzoin contains whitish almond-like tears diffused through its substance. Benzoin is obtained by making longitudinal or oblique incisions in the stem of the tree: the liquid which exudes soon hardens by exposure to the sun and air. Benzoin contains about 14 to 18 per cent. of Benzoic Acid (q.v.), although in some varieties this is either entirely wanting or replaced by 11 per cent. of cinnamic acid. A very fragrant oil, *styröl*, is present in small proportion (a few drops from a pound), the bulk of the gum consisting of resin. Benzoin is used in perfumery, in pastilles, and for incense, being very fragrant and aromatic, and

yielding a pleasant odour when burned. Its compound tincture is prepared by macerating benzoin, along with storax, tolu, and aloes, in rectified spirit for seven days, and subsequent straining, when the Compound Tincture of Benjamin (called variously Wound Balsam, Friar's Balsam, the Commander's Balsam, or Jesuit's Drops) is obtained. It is frequently applied to wounds directly; or is used as an exterior varnish over a bandage. In the preparation of court-plaster, sarcenet (generally coloured black) is brushed over with a solution of isinglass, and then with a coating of the alcoholic solution of benzoin. The tincture is likewise used in the preparation of soaps and washes. Benzoin possesses stimulant properties, and was formerly much used in medicine, particularly in chronic pulmonary affections. The name *Asa dulcis* (q.v.) was given to it in the 16th century.—The milky juice of *Terminalia benzoin*, a tree of the natural order of Combretaceæ, becomes, on drying, a fragrant resinous substance resembling benzoin, which is used as incense in the churches of Mauritius. It was erroneously supposed that benzoin was the produce of *Benzoin odoriferum*, or *Lindera benzoin*, a deciduous shrub of the Lauraceæ, a native of Virginia, about 10 to 12 feet high, which still bears the name of Benzoin, or Benjamin Tree, and is also called Spicewood or Fever-bush. Its highly aromatic bark is stimulant and tonic, and is used in North America in intermittent fevers. The berries are also aromatic and stimulant.

Benzol. See BENZENE.

Benzoyl, the radical of the benzoic series, represented by the formula C_6H_5O , is a hypothetical substance supposed to exist in benzoic acid and many other bodies. Thus, benzoic acid, from this point of view, is regarded as hydrate of benzoyl, C_6H_5OOH , and the oil of bitter almonds as the hydride of benzoyl, C_6H_5OH . As further examples of this group of bodies, we may mention benzoyl chloride, C_6H_5OCl , and benzoyl cyanide, C_6H_5OCN . *Dibenzoyl* (C_6H_5O)₂, or benzoyl, as it is sometimes called, may be looked on as the above-mentioned radical in the free state, and is prepared by the action of sodium amalgam on benzoyl chloride, in small colourless prisms, soluble in alcohol and ether.

HYDRIDE OF BENZOYL is the volatile or essential oil belonging to the benzoic series. It is represented by the formula C_6H_5OH , and has been already considered under ALMONDS, VOLATILE OIL or ESSENTIAL OIL of (q.v.).

Beowulf, an Old English poem of epic character, on the deeds of BEOWULF, a prince of the Geatas (the Götars of southern Sweden), who killed first Grendel, a monster of the moors and fens that had infested Heorot, the banqueting-hall of the Danish king Hrothgar; then Grendel's mother in her cave under a mere; and long afterwards, as the aged king of his own people, a dragon whose hoard had been rifled. His last victory costs him his life, and the poem ends with his cremation.

The only manuscript of the epic is a codex now in the British Museum, which once belonged to Sir Robert Cotton, and was much injured by the fire in the Cottonian Library in 1731. It is the work of two scribes. The handwriting of both is of the end of the 10th century. The poem consists of over 3000 alliterative lines, and is the oldest long poem in any Germanic tongue. Its language is West Saxon in the main, not without a sprinkling of forms which are not West Saxon. There is reason to believe that it was originally written in an Anglian dialect, most probably Mercian. The poem must be referred to a very early stage of English culture. Christianity had been intro-

duced, but the poet is describing an earlier world, a heroic age remarkably Homeric in temper and manners. The Christian touches are slight, yet the old heathen customs have begun to be forgotten; the Swedish antiquary Knut Stjerina found the poet inaccurate in his archæology. Evidence for date is indefinite, but such as it is it points to the early part or perhaps the middle of the 8th century. Of the poet nothing whatever is known. The characters of *Beowulf* are Geats and Danes; its scenes Heorot (probably Leine, near Roskilde) and the land of the Geats. Franks, Frisians, Swedes, and many other Germanic peoples the poet knows of: the English appear only in the digression on King Offa and his bloodthirsty queen Thryth, whose story belongs to the time when the English were still a Continental folk. It used to be thought, therefore, that *Beowulf* must be a translation from the Danish. What fragments remain, outside of *Beowulf*, of Old English heroic poetry prove that for subjects it ranged impartially over the whole Germanic world. The evidence of proper names, moreover, is conclusive. Such of the personages as have been traced in history or saga have names which exhibit all the sound-changes of the English language between their own time and the poet's; therefore they must have been transmitted through English channels, unless we are to suppose that the English writer was a philological expert. Thus Gregory of Tours and the author of the *Gesta Francorum* tell of the disastrous raid of Chochilaicus upon the Franks and Frisians about 512 or 520 A.D. Chochilaicus and its variants are Latinised representatives of the primitive form *Hugilaikaz*, which develops quite regularly into *Hygelac* in Old English. The raid is referred to in *Beowulf*, in which Hygelac is not a Danish king as in Gregory, but Beowulf's uncle, king of the Geats. Many of the Danish princes can be identified in the sagas and in Saxo Grammaticus. Hrothulf, Hrothgar's nephew and associate in the government, is seen to be no other than the famous Hrolf Kraki.

Beowulf himself, however, nowhere appears in history or tradition, and he is doubtless a fictitious interpolation in the Geatish royal line. Some confusion arises from the fact that there are two Beowulfs in the poem. Besides the hero there is an ancestor of the kings of the Danes, Beowulf the son of Scyld Seefing, who appears in the introduction only. Now the ancient English kings, not content with tracing their descent from Woden, carried it some generations beyond. In some West Saxon genealogies there appears among the ancestors of Woden, Beaw, son of Sealdwea or Scyld, whom Ethelwerd makes son of Scyf. It has been conjectured that owing to likeness of names the deeds of a corn-god Beaw have been attributed to the hero Beowulf, and Beowulf's name in exchange has been given to Beaw. Explanations of the story as a nature-myth long held the field, especially Müllenhoffs. Beaw (and so Beowulf) was regarded as a divine protector of mankind, representing cultivation and settled dwelling, his name assigned to the root *bhū*, 'to be, dwell, grow.' Grendel was a personification of North Sea's inundations in spring; his mother the depths. The dragon was the foul weather of the departing year, when the god's strength had waned. There was no lack of similar explanations. Grendel for some was a pestilence, or the grinding of the captive 'at the mill with slaves.' Even the swimming match with Breca was taken as a sun-myth. Breca represented the breakers, outstripped in their journey across the sea by Beowulf the sun-god. Nature-myths have lost their hold upon us. The mythological theories of Beowulf have been powerfully assailed by Professor Lawrence and others. Yet some

would find a residue of truth in them. Beow or Beaw seems indeed to have been a barley-spirit. For the story of Beowulf the Geat, however, parallels have been found in folk-tales. Dragon stories, of course, are plentiful enough. The adventures with Grendel and his mother belong to the class of tales called 'The Bear's Son.' Those elements in the Bear's Son cycle of stories which did not suit the poet's purpose have yet in some cases left traces to confirm the relationship. Especially close is the kinship between *Beowulf* and the stories of Grettir, of Orm, and of Bothvar Bjarki.

Since Ettmüller some have believed the work to be an amalgam of several poems. Müllenhoff maintained that the Grendel fight and the dragon fight were originally lays by different authors. To the first of these another poet added the fight with Grendel's mother, and yet another wrote the introduction. Interpolator 'A' added the story of Beowulf's home-coming, and inserted passages in the other parts; and then interpolator 'B' combined the whole of A's product with the dragon story and added most of the episodes, with moralisings and Christian theologisings. Other dividers have divided differently. A recent tendency is to grant that such a thing might have happened, but to deny that there is any evidence that it did happen. Scrutiny has failed to prove such differences in style as one should expect on the lay hypothesis. Moreover, the leisurely manner of narration is unlaylike. The poet might well have got his matter from lays, but hardly much of his text. Even the Christian elements in the poem, superficial and out of keeping as they seem to many, do not daunt the assertors of its unity.

The poem was first edited by Thorkelin (Copenhagen, 1815), afterwards by Kemble (London, 1838), Thorpe (1855), Thomas Arnold (1876), Harrison and Sharp (1883), Wyatt (1894; re-edited by R. W. Chambers, 1914), Sedgefield (1910), Klaeber (1922). German editions are those of Heyne (1863; re-edited by Schücking, 1918); Grein (1867; re-edited by Wülker, 1881); Zupitza, an autotype of the MS. (1882); Möller (Kiel, 1883); Holder (Freiburg, 1884); Trautmann (1904); Holthausen (1905-6, &c.). See translations by Kemble (1837), Thorpe, Arnold, Lumsden (1881), Garnett (1883), Earle (1892), William Morris and Wyatt (1895), Clark Hall (1895, 1914), Tinker (1902), Hyshe (1907), Gummere (1909), Scott Moncrieff (1921); the researches (in German) of Ten Brink (1888), Sarrazin, Müllenhoff, Sievers, Boer, Brandl, Morsbach, Panzer, Deutschbein, Schücking, Björkman; (in English) by Chadwick, Chambers, Lawrence, and Klaeber; (in Danish) by Olrik; Sweet in Hazlitt's edition of Warton's *History of English Poetry*; Morley, *English Writers* (1887); Stopford Brooke, *English Literature to the Norman Conquest* (1898); W. P. Ker, *Epic and Romance*; A. S. Cook, *Concordance to Beowulf* (1911); Knut Stjerna's *Essays on Questions connected with Beowulf* (trans. 1913); and R. W. Chambers's full and learned study (1921).

Bequeath (A.S. *bicwethan*), a word meaning originally to declare, and in the technical language of English law, to leave personal property by will to another. In Scots law the words bequeath and bequest are less used than in England. In both countries the expression 'leave and bequeath' is appropriate to the disposal of personal property, but in neither country would the courts defeat the intention of a testator to include his heritable or real estate, if that intention sufficiently appeared. See LEGACY, WILL.

Béranger, PIERRE JEAN DE, a popular song-writer of France, was born on the 19th August 1780, in the street of Montorgueil, in Paris. His father, a notary's clerk, had left his mother six months after their marriage, and Béranger was brought up by his grandfather, Champy, a tailor, until his ninth year, when he passed into the care of an aunt who kept an inn in the suburbs of Péronne. She was an

ardent republican, and appears to have taken pains to imbue her nephew with her political principles. From his fourteenth to his seventeenth year Béranger worked as apprentice to a printer in Péronne. He afterwards acted as a clerk to his father, who about this time gained a fortune by financial enterprises, only to lose it, however, in 1798. Béranger then settled in Paris, and gave himself to literature, living in the garret of which he has sung so charmingly, planning the most ambitious works (among them an epic on Clovis), and making careful studies of French style, until in 1804 distress compelled him to ask aid from Lucien Bonaparte. The assistance sought was willingly given; and about three years later the poet Arnault found Béranger a clerkship in the office of the Imperial University, a post which he held until 1821. On the publication of the first collection of his songs in 1815, he was recognised as the lyrical champion of the opposition to the Bourbons. His popularity with the working-classes was immense. It was for them that he always wrote, and they repaid him with an ardour of gratitude and admiration such as no other poet has excited in modern times. The *chanson*, in which the 18th-century writers had trifled in praise of love and wine, became in his hands a trenchant political weapon.

His politics, a curious compound of republicanism and devotion to the Napoleonic legend, exactly hit the taste of the multitude. His songs passed from mouth to mouth before they were published; since the invention of printing he is the only poet, it has well been said, who might have dispensed with the services of the press. For a time the government did not interfere, but two volumes which he published in 1821 led to a trial, at the close of which he was fined 500 francs and sentenced to three months' imprisonment in St Pélagie. Another volume, issued in 1825, was the cause of a second prosecution. Béranger was on this occasion fined 10,000 francs and condemned to nine months' imprisonment in La Force, where he was visited by Hugo, Dumas, Sainte-Beuve, and others of the greatest men of the day. In 1830 he published *Chansons Nouvelles*, and in 1840 he wrote the story of his life. In 1848 he was elected, against his will, by more than 200,000 votes to represent the Department of the Seine in the Constituent Assembly. He took his seat, but a few days afterwards begged to be allowed to resign. He rejected sundry offers of advancement from Napoleon III., and lived in retirement during his last years. He died at Paris on July 17, 1857. Béranger has been repeatedly compared to Burns, but he has neither the passion nor the deep humour of the Scottish poet. His songs cover a wide variety of subjects. Their vivacity and wit and tripping lightness of movement, their spontaneity and humanity, their gaiety which trembles into pathos, their satire which melts into laughter, their inimitable simplicity and seemingly unstudied grace of workmanship, explain and justify the unequalled popularity which their author secured and still retains among his countrymen. See *Ma Biographie* (Paris, 1857), and his correspondence edited by Boiteau (4 vols. 1859-60); also Jules Janin's *Béranger et son Temps* (Paris, 1866); Nivalet, *Béranger et son Œuvre* (1892); and Boule, *Béranger, sa Vie, son Œuvre* (1908).

Berar, or HYDERABAD ASSIGNED DISTRICTS, was until lately a central province of India, forming a commissionership under the resident of Hyderabad (Haidarabad); but since 1902-3, having been leased in perpetuity to Britain, it is practically incorporated with the Central Provinces, between which and the Nizari's Dominions it lies. It is 150 miles long by 144 broad; area, 17,711 sq. m.; population, 3,000,000. Berar consists of the districts of Amraoti, Ellichpur, Wun, Akola, Buldana, and

Basim, assigned to the British government under the treaties of 1853 and 1861 with the Nizam of Hyderabad, who was bankrupt, and unable to pay a large and increasing debt. The province is mainly a broad valley running east and west, between the Satpura Range in the north and the Ajanta Range on the south, and is divided into the *Balaghat* or upland country, and the *Payanghat* or lowland country. The valley at the base of the Satpuras, consisting of black loam, is extremely fertile, and is one rich sheet of waving crops in harvest time. It is traversed in its length by the Purna—itsself a tributary of the Tapi—which, with its numerous affluents, affords an ample supply of water to the valley, and it is thus peculiarly suitable for the cultivation of cotton, forming indeed the richest and most extensive cotton-field in India. The other products are millet, oil-seeds, wheat, pulses, tobacco, and castor-oil. Beds of coal are found near the Wardha River, in the Wun district; iron ore is plentiful in the east, and the only natural lake is the salt Lake of Louar. The Great Indian and Peninsular Railway runs through the province from east to west. Ellichpur (pop. 24,000) was the capital of the old kingdom. The British, under General Wellesley, helped the Nizam in 1803 to crush the Mahratta power.

Berat', a town of Albania, 30 miles NE. of the seaport of Avlona. It is the seat of a Greek archbishop. Pop. about 8000, a third of whom are Greeks.

Berber, a town on the right bank of the Nile, below the confluence of the Atbara, about 200 miles N. by E. of Khartum, was long the head of the great caravan route from the Nile to Suakin. It is mostly built of mud houses, and stretches for several miles on the east bank of the river. It is a station on the railway from Khartum to Cairo, and direct communication by rail with Suakin and Port Sudan through Atbara junction was opened in 1906. Pop. about 10,000.

Berbera, a seaport of British Somaliland, with a good harbour, on a bay of the Gulf of Aden. It was conquered by Egypt in 1875, but in July 1884 the British government took possession of it, and a small Indian force is now stationed there. It is the scene of a large annual fair, which brings over 30,000 people together from all quarters in the East. Coffee, grains, ghi, gold-dust, ivory, gums, cattle, ostrich-feathers, &c. are brought hither from the interior, and exchanged for cotton, rice, iron, Indian piece-goods, &c.

Berberid'æ, or **BERBERIDACEÆ**, a natural order of archichlamydeous dicotyledons, of which the different species of *Barberry* (q.v.) afford the best-known examples. Many of the plants of this order are spiny shrubs; others are herbaceous perennials. Their leaves are alternate; their flowers are usually in racemes, and are readily characterised by their trimerous symmetry and recurved anther valves; the fruit is either a berry or a capsule, and is usually acid, bitter, or astringent. There are more than 100 species, widely distributed through the temperate zone and on the mountains of the tropics, but absent from South Africa and Australasia.

Berbers, the general name usually given to the tribes inhabiting the mountainous regions of Barbary and the northern portions of the Great Desert. It is derived, according to Barth, either from the name of their supposed ancestor, *Ber*, which we recognise in the Lat. *A-fer*, an African, or from the Greek and Roman term *Barbari*. The name by which they call themselves, and which was known to the Greeks and Romans, is *Amázigh*, *Mazigh*, *Mazys*, &c. according to locality, and

whether singular or plural. These tribes have a common origin, and are the descendants of the aboriginal inhabitants of Northern Africa. They belong to the Hamitic family, and though they have been conquered in succession by the Phœnicians, Romans, Vandals, and Arabs, and have become, in consequence, to some extent a mixed race, they retain in great part their distinctive peculiarities. Till the 11th century, the Berbers seem to have formed the larger part of the population inhabiting the southern coast of the Mediterranean, from Egypt to the Atlantic Ocean; but, on the great Arab immigrations which then took place, they were driven to the Atlas Mountains, and to the desert regions where they now live. In Algeria, where they usually are termed *Kabyles* (*K'bila* = 'union'), they long remained unconquered by the French; and in Morocco, where they are called *Shelluh*, they are only in form subject to the sultan. The Rifs have given much trouble to the Spaniards. The Berbers occupying the desert, who are called *Tuareg* or *Tawarek* by the Arabs, have become much mixed with the negro race. The number of the Berbers is estimated at between eight and ten millions. They are of middle stature, sparsely but strongly built, and the complexion varies from reddish to yellowish brown. Their manners are austere, and in disposition they are cruel, suspicious, and implacable. They are usually at war either with their neighbours or among themselves, and are possessed of a wild spirit of independence, which makes it impossible for them to unite for any common purpose. They live in clay huts and tents, but in their larger villages they have stone houses. They have herds of sheep and cattle, and practise agriculture. The mines of iron and lead in the Atlas are wrought by them, and they manufacture swords, guns, and gunpowder. They formerly professed the Christian religion, but are now adherents of Islam. *A Dictionnaire Française-berbère* was prepared by Brosselard and Jaubert (1844). See also Renan, *La Société Berbère*; Jules Lionel, *Races Berbères* (1894); René Basset, *Contes Berbères*, with bibliography (1887), and *Nouveaux Contes Berbères* (1897); Sergi, *Africa* (1897). See AFRICA, BASQUES.

Berbice, the eastern division of British Guiana (q.v.), bounded on the E. by the Corentyn and Dutch Guiana. Area about 21,000 sq. m. Once a separate colony, Berbice was united with Essequibo and Demerara under one government in 1831. The chief product is sugar, with rum, molasses, timber, cocoa, and tropical fruits. The forests abound with splendid timber-trees, including the mora and bullet-tree. The Berbice River is navigable for small vessels 175 miles from its mouth. An important affluent is the Canje. New Amsterdam, on the right bank of the Berbice River (pop. 8000), is the chief town and port of the district. See GUIANA.

Berchem, or **BERGHEM**, NICHOLAS, an eminent Dutch painter, was born at Haarlem in 1620, and having studied under his father and Van Goyen, Weenix the elder, and other masters, he spent several years in Italy, where he soon acquired an extraordinary facility of execution. His industry was naturally great; and his innumerable landscapes now decorate the best collections of Europe. The leading features of Berchem's works, besides the general happiness of the compositions, are warmth of colouring, a skilful handling of lights, and a mastery of perspective. His etchings are also highly esteemed. He died in 1683.

Berchemia. See SUPPLE JACK.

Berch'ta (modern form *Bertha*, the Old High German *Perahta*, 'the bright'), a goddess of South German mythology, apparently the same as the

Hulda ('the gracious') of Northern Germany. In Dame Hulda, the gracious and kindly aspect came to be the predominant; but in Dame Berchta, the severe and awe-inspiring, the reason for this being that the popular Christian view had degraded her lower than Hulda. Dame Berchta has the oversight of spinners; whatever spinning she finds unfinished on the last day of the year she spoils. Her festival is kept with a prescribed kind of meagre fare—oatmeal-gruel, or pottage, and fish. If she catches any one eating other food on that day she cuts his stomach open, fills it with chopped straw, and sews up the gash with a ploughshare for a needle, and an iron chain for a thread. She is represented in some places as having a long iron nose and one big foot. It is likely that many of the attributes of Berchta were transferred to the famous Berthas of medieval history and fable, as Berta, wife of King Pippin and mother of Charlemagne. She has been connected with the feast of the Epiphany (6th January), and has been explained by some as a personification of the brightness of the heavenly vision that appeared to the shepherds in the field; but it is far more likely that the analogy of the 'bright' day was tacked on to a previously existing Perhta, a deity of heathendom. The numerous stories of the 'White Lady' (q.v.) who appears in noble houses at night, and acts as the guardian angel of the race, have doubtless their root in the ancient heathen goddess Berchta.

Berchtesgaden, a village of Bavaria, charmingly situated on a mountain-slope, about 15 miles S. of Salzburg. Its abbey was afterwards a royal castle, and in the neighbourhood is a former royal hunting-lodge. The place is most remarkable for its government salt-mines. Fresh water led into the mine is run off as brine into a reservoir, and conveyed to Traunstein and Rosenheim, 40 miles distant. The district was an ecclesiastical principality, secularised in 1803.

Berchtold, COUNT LEOPOLD, born 1863, was Austro-Hungarian foreign minister in 1912-15, presented the ultimatum to Serbia in 1914, and is held by many to be one of those chiefly responsible for the outbreak of war.

Berck-sur-mer, a French harbour and bathing resort in Pas-de-Calais, 22 miles S. of Boulogne, with some shipbuilding and sailmaking; pop. 10,000.

Berdiansk, a seaport of Ukraine (Taurida), has the finest harbour in the Sea of Azov, and is a place of commercial activity; pop. 33,000.

Berditchef, a town of Ukraine, 108 miles WSW. of Kiev by rail, famous for its five annual fairs; pop. 74,500, largely Jews.

Bere, a kind of Barley (q.v.).

Bereans, an almost extinct sect of Christians, who originated in Scotland in the 18th century. They took this name from the people of Berea, who are spoken of in Acts, xvii. 11, as having 'received the word with all readiness of mind.' Their founder was the Rev. John Barclay (1734-98), a native of Muthill, in Perthshire, who acted as assistant minister at Fettercairn for nine years. They believe that the knowledge of God's existence and character is derived from the Bible alone, and not from reason or nature; that the Psalms of David relate exclusively to Christ; that assurance is of the essence of faith; and that unbelief is the unpardonable sin. In other points of doctrine they are ordinary Calvinists.

Beregonium is a misprint in the Ulm edition of Ptolemy's Geography (1486) for *Berigonium*, a town of the Novantæ, now identified with the fort of Innermessan on the east shore of Loch Ryan. Boece applied the name Beregonium to a large

vitrified fort in Ardchattan parish, Argyllshire, 5½ miles NNE. of Oban. But there is no historical ground for supposing this to have been a seat of ancient kings, Scottish or other, as is often assumed.

Berengar I., king of Italy, succeeded at his father's death to the dukedom of Friuli. After the deposition of Charles the Fat in 887, he was crowned king of Italy, but he soon initiated the nobles by condescending to hold his territory in fief from Arnulf, king of Germany; and Guido, Duke of Spoleto, was persuaded to contest the throne. With the help of Arnulf, however, Berengar ultimately prevailed. After Guido's death in 894, his son, Lambert, compelled the king to share with him the sovereignty of North Italy until 898, when Lambert was assassinated. Berengar's influence quickly sank, since he could not check the plundering incursions of the Magyars and Arabs, and many years were spent in struggles to maintain his position. In 915 he was crowned emperor by Pope John X.; but the nobles again revolted, and under Rudolf of Burgundy completely overthrew him in 923. In his extremity, Berengar called in the Hungarians to his aid, which unpatriotic act alienated the minds of all Italians from him, and cost him his life, for he was assassinated in 924.—**BERENGAR II.**, grandson of the preceding, succeeded his father as Count of Ivrea in 925, and married Willa, niece of Hugo, king of Italy, in 934. For a conspiracy against Hugo, he was compelled to flee to Germany, where he was kindly received by the emperor, Otto I. In 945 he recrossed the Alps at the head of an army, and placed the weak Lothaire, the son of Hugo, on the throne. On the death of this prince, who was probably poisoned by Willa, Berengar allowed himself to be crowned along with his son, Adalbert, in 950. His tyranny induced his subjects to call in the aid of the emperor, who marched into Italy in 961, and took possession of the country. After three years' refuge in a mountain-fortress, Berengar surrendered, and was sent as a prisoner to Bamberg, in Bavaria, where he died in 966.

Berengaria. See RICHARD I.

Berengarius OF TOURS, a distinguished scholastic theologian, was born at Tours, in France, 998 A.D. In 1031 he was appointed preceptor of the school of St Martin in Tours, and, about 1040, archdeacon of Angers. Here he first drew upon himself the charge of heresy in reference to the doctrine of transubstantiation. He held that the bread and wine in the sacrament of the eucharist remained bread and wine, and that the faith of the believer who recognised their symbolic meaning only transformed them subjectively into the body and blood of Christ. This interpretation was condemned by Pope Leo IX. (1049-50). In 1054 Berengarius retracted his opinion before the Council of Tours, but immediately returned to his conviction, and commenced to advocate it anew. For this he was finally, in 1078, cited to appear at Rome, where he repeatedly abjured his 'error,' but never seems to have really abandoned it. Hildebrand, now Pope Gregory VII., treated him with great moderation; and at last conceived it best to let him alone. Harassed and weakened by the attacks of the orthodox party, headed by Lanfranc of Canterbury, he finally retired to a cell at St Côme, on an island in the Loire (now a ruin on the south bank), near Tours, where he spent the last years of his life in devotional exercises. He died in 1088. The greater number of his works are lost; such as are extant have been collected and published by A. F. & F. T. Vischer (Berlin, 1834).

Berenice (modern name, *Sakayt-el-Kubli*), a town of Egypt, on a bay in the Red Sea, 20 miles

SW. of Ras Benass. It was founded by Ptolemy Philadelphus, and was in ancient times the emporium of the trade with India, but it is now ruined, and interesting only for its antiquities.

Berenice, the name of several celebrated women of the house of Ptolemy, including (1) the wife of Ptolemy I., celebrated by Theocritus; the daughter of Ptolemy II.; and the wife of Ptolemy III. This last queen, during the king's wars in Asia, made a vow to offer her beautiful hair to the gods when her husband returned safely—a vow which she fulfilled. The hair was suspended in the temple of Aphrodite, from which, according to the fable, it was taken to form a constellation, *Coma Berenices*.—(2) **BERENICE**, also called Cleopatra, daughter of Ptolemy IX. (Lathyrus), was, on her succession to the throne, married to Alexander II., by whom she was murdered nineteen days after marriage.—(3) **BERENICE**, daughter of Ptolemy XI. (Auletes), eldest sister of the renowned Cleopatra, was raised to the throne after her father's deposition, 53 B.C., but was put to death when her father was restored, 55 B.C. She was first married to Seleucus, whom she caused to be put to death, and afterwards to Archelaus, who was put to death with her.—There were, besides, two Jewish Berenices—the one, daughter of Salome, sister of Herod the Great, and mother of Agrippa I.; the other, and more famous, was daughter of this latter monarch. She was three times married: her uncle, Herod, Prince of Chalcis, left her for the second time a widow, at the age of twenty; and she deserted her third husband to return to her brother, King Agrippa II., the same before whom Paul defended himself at Cæsarea. After the capture of Jerusalem, she went to Rome, and Titus, who was much in love with her, would have married her but for the opposition of the people. The intimacy of Berenice and Titus forms the subject of a tragedy by Racine.

Beresford, **WILLIAM CARR BERESFORD**, VISCOUNT, general, was born in 1768, a natural son of the first Marquis of Waterford. He entered the army in 1785, in 1786 lost his left eye through an accident, and, after serving in all the four continents, bore a conspicuous part (1806) in the reconquest of the Cape, and the capture of Buenos Aires. The latter achievement was followed by his own surrender, but in 1807 he made his escape. In 1808 he did gallant service during the retreat to Corunna; and in 1809 he took the command of the Portuguese army, with the local rank of lieutenant-general. He succeeded in improving its discipline so greatly, as soon to render it highly efficient for active service. For his services at Busaco (1810) he was made a Knight of the Bath; and for his victory over Soult at Albuera (1811) he received the thanks of parliament. He was present at Badajoz, and at Salamanca, where he was severely wounded, and distinguished himself in many other battles. In 1814 he was created Baron, and in 1823 Viscount. In 1828–30 he was master-general of the ordnance. He died 8th January 1854.—Admiral Lord **CHARLES WILLIAM BERESFORD**, first Baron Beresford (1916), K.C.B., G.C.V.O. (1846–1919), a son of the fourth Marquis of Waterford, distinguished himself at Alexandria and elsewhere in Egypt and the Sudan in 1882–86, was a lord of the Admiralty (1886–88), but resigned, sat in parliament as a Conservative, and commanded the Channel Fleet and in the Mediterranean. He was a vigorous critic in naval affairs. See his *Memoirs* (2 vols. 1914).

Beresina, or **BEREZINA**, a river of White Russia, flows southward for 350 miles (over 200 of which are navigable) to the Dnieper, and is connected with the Duna by a canal, communica-

tion between the Black and Baltic Seas being thus established. The Beresina is memorable on account of the disastrous passage of the French army, November 1812, during the retreat from Moscow. Two bridges over the river were hastily constructed amid terrible hardships, and, on the 27th, the passage of the French commenced, and went on throughout the whole day. Marshal Victor's rear-guard of 7000 men, under Partonneaux, were, however, intercepted by the Russians, and had to capitulate. On the 28th a vigorous attack was made by the Russians upon the French on both sides of the river; and they established a battery of twelve pieces to command the bridge. The panic and confusion of the French became dreadful. One bridge broke, and all rushing to the other, it was soon choked; multitudes were forced into the stream, while the Russian cannon played on the struggling mass. On the 29th a considerable number of sick and wounded soldiers, women, children, and sutlers still remained behind, until preparations were completed for burning the bridges. Then a fearful rush took place. Some 10,000 dead bodies were found on the shores of the river when the ice thawed; and the Russians took 16,000 prisoners and 25 pieces of cannon. Yet the passage of the Beresina, great as were the losses, was the one French achievement of the war. See *Napoleon* ('Cambridge Modern History,' vol. ix. 1906).

Bereslav, or **BERISLAV**, a thriving town in Ukraine, on the Dnieper, trading in wood and corn; pop. 12,000.

Beret, the cap of the Basques (q.v.).

Berezna, a town of Ukraine, 30 miles E. of the town of Tchernigoff, on a tributary of the Desna; pop. 10,000 (many Jews).

Berezov ('the town of birch-trees'), a small town of Siberia in the government of Tobolsk, on the left bank of the Sosva, a branch of the Obi. It marks the northern limit of the region of rye, barley, and horses, and is important as a fur and skin trading station.

Berezovsk, a village in the Russian province of Perm, near Ekaterinburg, gives name to a famous gold-field, wrought since 1744. The mines are on the eastern slopes of the middle Ural chain, and the field is above 5 miles long. The washings on the Berezovka River are also very productive.

Berg, a former duchy of Germany, on the right bank of the Rhine, now incorporated with the Prussian dominions, between Dusseldorf and Cologne. It is a densely populated manufacturing country. After various vicissitudes, the duchy had merged in the electorate of Bavaria, and in 1806 Bavaria ceded it to France. Napoleon erected it into a grand-duchy, constituting his brother-in-law, Murat, its sovereign; and two years afterwards, Napoleon's nephew, then Crown Prince of Holland, was made grand-duke. The peace of 1815 gave Berg to Prussia.

Berg, **CHRISTIAN PAULSEN**, Danish politician, born in 1829, near Lemvig, in Jutland, in 1865 entered the Folkething, of which he was chosen president in 1883. In 1877 he became leader of the Radical opposition, and in 1881 editor of the *Morgenblad*; in 1886 his fierce attacks on one of the ministry brought on him six months' imprisonment. He died 27th November 1891.

Berga, a town of Catalonia, Spain, 52 miles NNW. of Barcelona. Pop. 5000.

Bergama (ancient *Pergamos* or *Pergamon*), a city of Asia Minor, situated in a beautiful and fertile valley, 40 miles N. of Smyrna. In early times the city was the capital of the king-

dom of Pergamum (q.v.). The present population is about 6000.

Bergamo (the ancient *Bergomum*), a fortified town of Lombardy, situated on low hills, 34 miles N.E. of Milan by rail. It has a castle occupying the most elevated part of the town, a cathedral, school of art, museum, lyceum, library, two theatres, &c. Silk, cotton, linen, woollen fabrics, and iron goods are manufactured. It has also an extensive trade in grindstones, quarried in the vicinity. Annually, in the month of August, the largest fair in North Italy is held here. Bergamo was destroyed by Attila, 452 A.D.; after the fall of the Roman empire, it became capital of a Lombard duchy, and its inhabitants placed themselves under the protection of the Venetian Republic in 1427. It is now capital of an Italian province. Tiraboschi and Donizetti were natives of Bergamo, and Bernardo Tasso, the father of Torquato, was of Bergamasco descent. The population of the commune is 55,550.

Bergamot is the name applied to a group of varieties of pear, which agree in more or less completely resembling an apple in shape, in melting juicy pulp, and pleasant flavour. See PEAR.

Bergamot is also the name of a species or variety of the genus *Citrus* (q.v.), also called the BERGAMOT ORANGE, or MELLAROSA; by some botanists regarded as a variety of the orange (*C. Aurantium*); by others, as a variety of the lime (*C. limetta*); and elevated by Risso to the rank of a distinct species, under the name of *C. bergamia*. The name comes from Bergama (q.v.), a city in Asia Minor, the ancient Pergamos. It is now cultivated in the south of Europe; and from the rind of its fruit, the well-known Oil of Bergamot is obtained, which is extensively used in making pomades, fragrant essences, eau de Cologne, liqueurs, &c. The fruit is pear-shaped, smooth, of a pale-golden colour, and has a green, subacid, firm, and fragrant pulp. The essential oil is obtained by distillation, or by grating down the rinds, and then subjecting them to pressure, which is the better method. The oil is also obtained from other varieties or species of the same genus. It is of a pale-yellow colour or almost colourless. One hundred Bergamot oranges are said to yield about 2½ ounces of oil. Oil of Bergamot is frequently employed for diluting or adulterating the very expensive blue volatile oil of Chamomile (q.v.).—BERGAMOT is also applied to certain fragrant Labiates, notably *Mentha citrata* or *odorata*, as also to species of *Monarda* (*M. fistulosa*, &c.).

Bergedorf, a district and town of Germany, 10 miles S.E. of Hamburg, to which it belongs. Part of the territory is known by the name of the Four Lands (*Vierlander*). It is inhabited by a well-conditioned and industrious population, much occupied in the cultivation of fruit and vegetables, not only for the market of Hamburg, but for that of London. The area is 35 sq. m., and the population about 30,000. Pop. of town, 17,000.

Bergen, a fortified seaport in the west of Norway, and the second city of the kingdom, in the province of the same name, situated on a promontory at the head of a deep bay, and, with the exception of the north-east side, where lofty mountains inclose it, surrounded by water. The harbour is safe and commodious, and around it the town is built, presenting a picturesque appearance from the sea, with its wooden houses of various colours. It has a cathedral, various churches, schools, hospitals, and public institutions; and is the seat of a bishop, and the station of a naval squadron. The museum has valuable collections of Norse antiquities and specimens of

Norwegian fishes. The chief manufactures of Bergen are gloves, tobacco, porcelain, leather, soap, and cordage. It has numerous distilleries, and several shipbuilding yards. Its principal trade, however, is the export of stockfish, herrings, and fish-oil and roe. Twice a year, the Norlandmen come to Bergen with their fish, receiving in exchange for them such articles of necessity or luxury as they require. The annual value of the stockfish exported from this port is about £450,000. In addition, it exports about half a million barrels of herrings and 20,000 barrels of cod-liver oil. There is constant steam communication with Copenhagen, the Baltic ports, Hamburg, Rotterdam, Hull, Newcastle, and New York. Since 1883 Bergen has been connected by railway with the north of the Hardangerfjord. The chief imports are brandy, wine, corn, cotton, woollens, hemp, sugar, tobacco, coffee, &c. The climate is exceedingly humid, but not unhealthy; the yearly rainfall is 89 inches, and the temperature averages 46° F. Bergen, formerly called Bjørgvin ('the pasture betwixt the mountains'), was founded about 1070 by Olaf Kyrre, who made it the second city in his kingdom, and it was soon raised to the first rank. English and Scottish traders were early displaced here by the merchants of the Hanse towns, who continued to exercise and abuse their monopoly until their supremacy was broken by an act issued by Frederick II. of Denmark in 1560; and in 1763 their last warehouse fell into the hands of a citizen of Bergen. In the 13th century, Bergen had thirty churches and religious houses, but these have been mostly swept away in the numerous conflagrations which have devastated it from 1189 to 1916. The town was long the most important trading town of Norway, but has been outstripped by Christiania. The castle of Bergenhus was till 1397 the residence of the Norwegian kings. Bergen was the birthplace of Holberg, the painter Dahl, Welhaven, Ole Bull, and Grieg. Pop. 90,000.

Bergen-op-Zoom, a town formerly strongly fortified, in the Dutch province of North Brabant, 21 miles N. by W. of Antwerp, and 39 E. by N. of Flushing. It stands on the little river Zoom, at its entrance into the east branch of the Scheldt, in a marshy district, frequently inundated. It has a harbour, manufactures of brick and earthenwares, and a large trade in anchovies. Population, 15,000. The importance of its position rendered the town the object of many contests. The Netherlands made it one of their strongholds in their struggles with Spain, and the Spaniards, who had been expelled in 1577, unsuccessfully attempted to capture the place, either by siege or storm, in 1581, 1588, 1605, and 1622. The fortifications were afterwards strengthened by the engineer Coehorn, so as to give it the reputation of being impregnable. Yet the French, under Count Lowendal, in 1747, after a siege of nearly three months, and the springing of 41 mines by the assailants, and 38 by the defenders, took the place by storm, and in 1795 it capitulated without resistance to Pichegru. Being incorporated with France in 1810, it was blockaded in 1814 by the English, who attempted to surprise the fortress on the night of the 8th of March with a force of 3900; but after carrying the greater part of the works, they were, through Sir Thomas Graham's remissness in sending support, overpowered by the brave garrison, and either slain or forced to surrender. The French only gave up the post under the Treaty of Paris; in 1867 the fortress was demolished.

Bergenroth, GUSTAV ADOLF, historian, born in Prussia, 1813, studied law, and entered the state service, from which he was dismissed, owing to his

revolutionary views, in 1848. Becoming further compromised, he went to America in 1850, but settled in 1857 in England, where he devoted himself to the study of the state papers of the Tudor reigns. After a visit to Simancas, in Spain, he published his great *Calendar of Letters, Despatches, and State Papers relating to the Negotiations between England and Spain* (3 vols. Lond. 1862-68). He died in Madrid, 13th February 1869.

Bergerac, a town in the French department of Dordogne, on the Dordogne, 60 miles E. of Bordeaux, with ironworks and distilleries, and a trade in wine, chestnuts, and truffles; pop. 11,000.

Bergerac, SAVINIEN CYRANO DE, a French author, born in Paris 1619, distinguished for his courage in the field, and for the number of his duels, more than a thousand, most of them fought on account of his monstrously large nose. He died in 1655. His writings, which are often crude, but full of invention, vigour, and wit, include a tragedy, *Agrippine*, and a comedy, *Le Pédant Joué*, from which Corneille and Molière borrowed ideas; and his 'comic histories of the empires of the sun and moon' probably suggested 'Micromégas' to Voltaire, and 'Gulliver' to Swift. He was a pronounced free-thinker. His name and his nose have been rendered familiar by Rostand's comedy (1898). See two books by P. A. Brun (1893, 1909).

Berghaus, HEINRICH, an eminent geographer, was born at Cleves, in Rhenish Prussia, in 1797. His early services as an engineer in the French and Prussian armies largely advanced his knowledge of geodesy. After being employed on the trigonometrical survey of Prussia, he became (1824) professor of Mathematics in the Architectural Academy of Berlin, and (1836) director of the Geographical School in Potsdam. The best known of his cartographical works is his *Physical Atlas*. He edited several geographical periodicals, and wrote numerous valuable works on physical and political geography, including the *Länder- u. Völkerkunde* (1840). His correspondence with A. von Humboldt, published at Leipzig in 1863, fills 3 vols. He died at Stettin, 17th February 1884.

Berghem. See BERCHEM.

Bergk, THEODOR, a distinguished German classical scholar, born at Leipzig, 22nd May 1812. From 1842 to 1869 he was professor of Philology successively at Marburg, Freiburg, and Halle. In the latter year ill-health enforced his retirement, and the remainder of his life was spent in preparing his *Geschichte der griechischen Litteratur*, of which, however, he finished the first volume only (Beil. 1872), the other three being edited by G. Hinrichs (1883-88). Bergk's chief complete work is his *Poetae Lyrici Graeci* (3 vols. Leip. 1843). He also published numerous papers on philology and editions of individual Greek poets. He died 20th July 1881.

Bergman, TORBERN OLOF, a celebrated Swedish chemist, born at Katharinaberg, in West Gothland, 20th March 1735. A student under Linnaeus at Uppsala, he was raised in 1758 to the chair of Physics there, and in 1767 to that of Chemistry. He died 8th July 1784. Bergman's earliest studies were in natural history; his later, in chemistry and mineralogy. His theory of elective or chemical affinities had an important place in the history of chemistry, and his work in mineralogy did much to prepare the way for a scientific classification of minerals. His dissertations are collected into 6 octavo vols. (Leip. 1779-81); and English translations of them fill 3 vols. (1784-85).

Bergmehl, or MOUNTAIN-FLOUR, is a recent deposit of a white or cream-coloured powder of extreme fineness, composed almost entirely of the indestructible siliceous frustules or cell-walls of

Diatoms (q.v.). From its resemblance to flour, it has been mixed with ordinary food in seasons of scarcity, and thus used by the inhabitants of Norway and Sweden, who suppose it to be nutritious. When subjected to a red heat, it loses from a quarter to a third of its weight, the loss consisting probably of organic matter, and this would make it in itself nutritious; but it seems to derive its chief value from its increasing the bulk of the food, and rendering the really nutritious portion more satisfying. On the other hand, some experiments tend to show that bergmehl does contain a very small proportion—3 or 4 per cent.—of positive nutriment. Similar deposits occur at Dolgelly in North Wales, at South Mouine in Ireland, and in Mull, Raasay, Skye, and elsewhere in Scotland. The contained organisms show that these beds have been deposited in fresh water.

Bergschrund, a crevasse formed where a glacier or snow-slope starts away from the mountain-side.

Bergson, HENRI LOUIS, born in 1859, professor of Philosophy at the Collège de France, Paris, is one of the outstanding thinkers of the present time. His chief works—which are no less remarkable for the brilliance of their style than for the striking character of the views they set forth—are (1) *Essai sur les Données immédiates de la Conscience*, 1889 (Eng. trans. under the title of *Time and Free-will*, 1910); (2) *Matière et Mémoire*, 1896 (Eng. trans. 1911); (3) *Le Rire*, 1900 (Eng. trans. 1911); (4) an article in the *Revue de Métaphysique et de Morale* called 'Introduction à la Métaphysique,' 1903 (Eng. trans. 1913); (5) *L'Évolution créatrice*, 1907 (Eng. trans. 1911); (6) *L'Énergie spirituelle*, 1919 (Eng. trans. 1920). In the present article it must suffice to indicate some of the main ideas presented in 1, 4, and 5.

The original aim of the *Essai* was to deal with the problem of free-will, but the book as a whole really covers a much wider ground. It asserts in the strongest form that doctrine of the polar opposition between consciousness and the world of things in space, which is one of the most fundamental doctrines of Bergson's philosophy. The external world, as science knows it, is a world of discrete measurable things, whose ultimate or atomic elements may undergo rearrangement, but never really change, and whose relations are rigidly determined by mechanical laws. Consciousness is for Bergson the polar opposite of all this. It is complex yet indivisible; for all its partial phases and successive stages interpenetrate each other. It is wholly qualitative: when we attribute quantitative determinations to it, we do so by a confusion—e.g. when we call one sensation more intense than another we are describing an experienced difference between the sensations in language which is really appropriate, not to the sensations themselves, but to the stimuli which cause them. Above all, consciousness is characterised by 'duration'—i.e. by a continuous change or flux of content. To get at the full meaning of this cardinal term in Bergson's philosophy it is best to begin by way of contrast. Scientific psychology has long recognised that consciousness is incessantly changing, but then it represents this changing consciousness as consisting of a series of successive states or ideas, and thereby fatally obscures the very fact which it is trying to express. For it is the very essence of the flux of consciousness to be continuous, to be incapable of being split up into discrete states or elements, to be always growing and expanding, to carry on the past into the present without a break. And just because consciousness is thus always moving forward, while it yet retains in a sort of cumulative memory an ever-lengthening

past, it never repeats itself. There is always in consciousness an aspect of novelty or unpredictability. It is here that Bergson's view of free-will attaches itself to his view of consciousness. Looking back on the past we seem to be able to trace a necessity of sequence even in consciousness, but this is only because the sequence is already complete. From the creative present, on the other hand, the aspect of novelty can never be eliminated. True, we form habits, and the more we surrender ourselves to their guidance, the more possible a sort of approximate prediction becomes. But prediction is never possible in all its fullness, and it is less and less possible in proportion as we resist the deadening influence of habit and concentrate our whole soul on the decision before us. It is in such moments of full concentration—which Bergson regards as rare—that we rise to true freedom of will.

In describing the flux of consciousness Bergson makes a free use of metaphors and images—e.g. the phases of consciousness are said to melt into each other like the colours of the spectrum. He does this deliberately, because in his view the intellect, triumphant in the sphere of mechanical and mathematical science, is incapable of grasping the real nature of 'duration.' Its method is that of conceptual analysis: it is always trying to break up its object into simple elements and to characterise it by means of fixed and sharply defined concepts. Now this is a method which answers admirably when we are dealing with a world of things occupying distinct positions in space and consisting of a matter that is at bottom inert and changeless. The intellect, in fact, is essentially adapted for this very purpose of dealing with the external world: it is an instrument of action. But its method becomes less and less applicable as we pass to facts of life and consciousness, and have to deal with continuous movement. When a person lifts his arm (to take one of Bergson's favourite illustrations) he is conscious of the movement in its unity and singleness, whereas for an external observer the movement appears as a series of positions. Now the intellect can never by adding together successive positions recover the inner unity of the movement as experienced. To grasp this inner unity we must have a kind of apprehension distinct from intellect, an immediate intuition, in which consciousness, turning sharply away from the external world, becomes aware of its own true nature. Only when we have thus grasped directly, in our own conscious experience, the meaning of 'duration' are we prepared to interpret sympathetically other forms of life.

Convinced that in 'duration' he has found 'the very stuff of reality,' Bergson seeks in his *Creative Evolution* to apply this insight beyond human consciousness to the whole evolution of life on earth, and even to the ultimate nature of reality. Life and consciousness show themselves in other forms than the human. Over against the human intellect, e.g., must be set animal instinct, which reaches perhaps its highest development in comparatively low forms of life. Thus behind these specialised forms of consciousness, behind even the contrast of vegetable and animal life, we are led to assume some original 'vital impulse,' which is seeking in diverse ways to realise itself against the obstacles which its material environment opposes to it. Bergson proceeds, accordingly, to sketch out on these lines a view of evolution for which he claims a higher truth than is possessed by current views, whether of a more mechanical or a more teleological cast. Finally, a still bolder flight of metaphysical intuition remains to be made. Matter itself must be brought into relation with the 'duration' or inner life—the creative activity

—of the universe as a whole. Viewed in this way it is seen to be, not a new or additional sort of reality, but simply a result of the interruption or relaxation of the creative activity itself. On this more metaphysical side of his philosophy, however, Bergson's views are not yet fully worked out.

There are brief expositions of a popular kind by H. Wildon Carr (in 'People's Books' series) and J. Solomon (in Constable's series); more technical discussions by A. D. Lindsay, *Philosophy of Bergson*, and J. McKellar Stewart, *A Critical Exposition of Bergson's Philosophy*. William James's enthusiastic appreciation of Bergson's 'Critique of Intellectualism' in *A Pluralistic Universe* indicates the point of contact between Bergson and Pragmatism. There is a bibliography of writings by and on Bergson in the Eng. trans. of the *Essai*.

Bergues, a town in the French department of Nord, on the Colme, 5 miles SSE. of Dunkirk, fruitlessly besieged by the English in 1793; pop. 5500.

Bergylt (*Sebastes norvegicus*), a common fish in northern seas, belonging to the family Scorpenidae, in the great order of fishes with spinous rays (*Acanthopterygii*). It is somewhat like a perch in appearance, and used to be called *Perca marina*; no resemblance, however, can justify another of its names—the Norway Haddock. It attains a length of 2 feet or more, has a red colour, and is good for food. Though occasionally found on British coasts as far south as Berwick, its true home is farther north. The genus *Sebastes* includes 24 other widely distributed species.

Berhampur, the name of two towns in British India. (1) Berhampur, in Madras, is a military station in the district of Ganjam, 18 miles SW. of the town of Ganjam, and 9 from the coast. The climate is very healthy, and there is some trade in sugar and silk cloth. Pop. 31,500. (2) Berhampur, in Bengal, on the left bank of the Bhagirathi, 5 miles below Murshidabad. It was long one of the principal military stations in British India, and the barracks, now largely devoted to other uses, still form its most prominent feature. In 1857 Berhampur was the scene of the first open act of mutiny. Pop. 26,000.

Beriberi (from the Singhalese *beri*, 'weakness'), a form of neuritis common in India, Japan, and parts of Africa, which combines anæmia, pain, and difficulty in breathing, with diopsical and paralytic symptoms. It may be acute or chronic, and is not contagious, but infests districts. It was observed that persons fed on milled or 'polished' rice suffered from it; but if the 'polishings' or pericarp were again added to the decorticated grain, the rice could be eaten with impunity. British soldiers fed on white bread and tinned meat suffered, while Indian troops fed on coarsely ground wheat and pulse did not; nor did the British when their own flour ran short and Indian wheat was given them. It is now recognised that a vitamin or 'accessory food substance' necessary for growth and health (though only a minute quantity is required) is contained in the wheat embryo, removed by European methods of milling. This vitamin occurs also in milk, eggs, pulse, and yeast. It is destroyed by the high temperatures used in sterilising tinned foods.

Bering. See BEHRING.

Berislav. See BERESLAV.

Berja, a town of Spain, 22 miles W. of Almeria, with lead-mines; pop. 15,000.

Berkeley, a small town of Gloucestershire, on the Avon, 15 miles SW. of Gloucester by rail. The town lies in the Vale of Berkeley, which consists of rich meadow pasture-land, on a deep, fat loam, and is celebrated for its dairies and 'Double Gloucester' cheese. Berkeley Castle,

on an eminence to the south-east, about 1162 was granted by Henry II. to Robert Fitzhardinge, with whose descendants it has since continued for more than seven centuries, they having held the title of Baron Berkeley from 1295, and of earl and viscount from 1679. Here Edward II. was murdered in 1327. In the civil wars of Charles I., the castle held out for the king, but was taken after a nine days' siege by the Parliamentarians. Dr Jenner was a native of Berkeley, and was buried in the parish church. See John Smyth's *Lives of the Berkeleys, from 1086 to 1618*, ed. by Sir John Maclean (2 vols. 1883-84).

Berkeley, a city of California, overlooking the Bay of San Francisco, partly burned in 1923, is the seat of the state university; pop. 56,000.

Berkeley, GEORGE, Bishop of Cloyne, an historical figure in the 18th century, whose romantic life of unselfish enthusiasm and self-sacrificing philanthropy animated a metaphysical genius still powerful in philosophical speculation. He was born in the neighbourhood of Kilkenny, on the 12th of March 1685 (N.S.), according to reliable tradition, in the half-ruined castle of Dysert, on the bank of the Nore. He was a scion of the noble House of Berkeley; his mother was a Wolfe, of the same Irish family as the hero who afterwards fell at Quebec. At the age of eleven he was sent to the Duke of Ormond's School at Kilkenny, from which he proceeded, in his fifteenth year, to Trinity College, Dublin. There he continued to reside, as student and fellow, for thirteen years. Trinity College was then influenced by independent thinkers. The philosophy of John Locke, which gave form to, and expressed the spirit of the 18th century, was already in vogue there, and, along with Descartes and Malebranche and the new physics of Newton, was superseding medieval scholasticism. To these stimulating influences the young student from Kilkenny responded with characteristically ardent enthusiasm. A *Commonplace Book* of 1705-6, lately discovered, and first published in the collected edition of his works in 1871, reveals an intellectual fermentation of extraordinary interest. Throughout its pages we see a subtle and original mind, stimulated by Locke's psychology to a conception of the universe which Locke himself never consciously approached.

The ardent spirit of the *Commonplace Book* soon found vent in philosophical authorship. Its 'new principle' was soon given to the world, first in its application only to our visual perception of things, and then, in two succeeding treatises, with philosophical comprehensiveness, as a system of universal immaterialism in which the whole world of sense is spiritualised. Accordingly, in 1709, he produced an *Essay towards a New Theory of Vision*, the purpose of which was to show that the act of seeing, which seems so immediate and indecomposable, is not really a direct and inexplicable revelation of something outside all self-conscious intelligence, but is an act of interpretation, involving a process essentially (if unconsciously) rational, which presupposes too a rational or orderly constitution in the visually interpreted phenomena themselves. The *Essay* is thus a psychological analysis of visual perception, with an ontological outcome. It was Berkeley's first step towards a clarification of the confused popular, and self-contradictory philosophical conceptions of matter, by its translation of the semi-conscious processes of sight into a virtual recognition of the perpetual creative agency of Supreme Reason. The argument was enlarged in scope in a *Treatise on the Principles of Human Knowledge*, in 1710, followed in 1713 by *Dialogues between Hylas and Philonous*, in which the new conception of matter

is popularised. These three books set in motion in Europe a train of speculation which, slow at first, through popular and philosophical misunderstanding, has not ceased since to move human thought about all the ultimate questions of our life and our surroundings. The central conception of the three continued to develop in Berkeley's mind throughout his life. His 'new principle'—that the world which we see and touch is not an abstract independent substance, of which conscious mind may be an effect, but is the very world that is presented to our senses, and which depends for its actuality on being perceived—was long misconstrued as the monstrous paradox that matter has no perceived existence. We are only now learning to realise, through its help, that phenomena in a sense presuppose the presence and continual agency of Supreme Reason; that external nature is thus throughout and always supernatural; that the orderly evolution of its sense phenomena, in inorganic and organic things, interpreted in natural science, is, for mere science, only a succession of phenomena, but that to the eye of philosophy these phenomena are severally and collectively dependent on the immanence of Reason, and ultimately on the moral agency of Spirit—so that the evolution of finite things, even in an endless succession, is in no way inconsistent with their being the subjects of constant creative activity. The material world of Berkeley is just what the senses present: all in it beyond this belongs to the world of mind, which converts the presented phenomena into a language that is expressive of absent sense phenomena, of other finite spirits, and of the all-pervading Reason that is supreme and absolute. What we know beyond sense phenomena is their intelligible synthesis in the form of variously qualified things. Our objective perception of this external or interpretable world is reached, not through any single sense, but through sense symbolism, which enables us to connect what is actually present in one sense with what is conditionally presentable in the others. Belief in the real existence of the external world is belief in the permanence of this intelligible connection among sense phenomena. This belief presupposes that we are in a trustworthy and intelligible universe, in which the sense signals presented to us to regulate our lives by may be depended on. Our security for the reality of the Berkeleyan external world is the thus inevitable assumption that nature is reasonable; that its phenomena express thought akin to our own; that it is more or less interpretable by us in progressive physical or natural science; and that even in the world of the senses we are living and moving and having our being in the supreme all-pervading Reason, theologically called God.

In 1713 Berkeley went to London, and was introduced by his countryman Swift to the statesmen and men of letters who there formed a brilliant society in the reign of Queen Anne. After spending nearly a year in London, he gave seven years to travel in France and Italy, first as chaplain to the brilliant and eccentric Earl of Peterborough, and afterwards as tutor to a son of the Bishop of Clogher. His journals, lately recovered, contain vivid descriptions of this continental experience, including adventures in crossing Mont Cenis in winter, a perilous visit to the crater of Vesuvius during an eruption, and an interview and metaphysical discussion at Paris with the aged Malebranche.

On his return to Ireland in 1721 he was distressed by the symptoms of social corruption and disorder occasioned by the South Sea Mania. This was the beginning of his public career as a missionary-philanthropist in pursuit of ideals for society. His sociological thoughts first found

expression in a short *Essay towards preventing the Ruin of Great Britain*, charged with suggestions economical and ethical, significant of his own chivalrous indifference to wealth. In 1724 he resigned his fellowship in Trinity College, on being made Dean of Derry, with an income of £1100, which put him for the first time in easy circumstances. Yet that very year he carried to London a letter from Swift to Lord Carteret, the lord-lieutenant of Ireland, bearing that it was 'to introduce an absolute philosopher with regard to money, titles, and power, who for three years past has been struck with the romantic notion of founding, by a charter from the crown, a college at the Bermudas for the Christian civilisation of America, where he exorbitantly proposes a whole hundred pounds a year for himself as its head, and whose heart will break if his deanery be not for this purpose taken from him.' With a foresight of our vast colonial empire, he laboured in London for three years to interest Sir R. Walpole and other leading politicians in this missionary project, the grandest conceived in the 18th century. At last £20,000 was voted by the House of Commons for the endowment. On the faith of this he sailed for America in September 1728, taking with him a congenial auxiliary in his newly-married wife. To prepare for Bermuda, he made a romantic temporary home for himself for nearly three years in Rhode Island, where a few years before some American missionaries had settled. In one of them, a Dr Samuel Johnson, he found congenial companionship and a philosophical disciple, whose works, as well as those of Jonathan Edwards, helped to propagate his metaphysical conception of matter in America. Berkeley never reached Bermuda, as the promised grant was in the end withdrawn. In the autumn of 1731 he returned to England, carrying with him literary fruit ripened in Rhode Island, in 'the still air of delightful studies,' and given to the world in 1732 under the title of *Alciphron, or the Minute Philosopher*, the most finished of his works, with pleasant pictures of American scenes and life, while in form and ideas it resembles dialogues of Plato. Its philosophy cannot be out of date as long as agnostic contention with personality in man and God is continued. *Alciphron* was followed in 1733 by a *Vindication* of Berkeley's early visual immaterialism. In the *Analyst*, published in 1735, his theological philosophy was further unfolded, in an argument meant to show that the higher mathematics involve assumptions which as truly exclude definite or exhaustive conception as do any of the mysteries of religion, and which equally with the latter illustrate the spiritual fact, that the ultimate or marginal conceptions of an intelligence like ours must be only half-conceived truths.

Meantime, in 1734, Berkeley was made Bishop of Cloyne, in the south of Ireland, where in a beautiful home-life of eighteen years he found a channel for his ardent philanthropy in devotion to the social problems of Ireland. Two years after he went to Cloyne, he began the publication of the *Querist*, which appeared, in that and the two following years, in three instalments, consisting of about five hundred questions suggested by Ireland, with 'more hints, then original, still unapplied, in legislation and political economy than are to be found in any equal space.' The *Querist* was followed, in succeeding years, by other pamphlets on Ireland, and appeals for a larger toleration of its religious differences. The medical virtues of tar-water, on which he had been experimenting, were characteristically connected in Berkeley's mind with the ultimate conceptions of religious philosophy. In 1744 he published *Siris*, or a chain of philosophical reflections on the virtues of tar-water, a treatise which he said cost

him more research and thought than any of his other works. Through the crude mechanics, chemistry, and physiology of a past age, it suggests a connection between the resinous element in tar and the Spiritual Power by which the universe is being perpetually created. Plato and the Neo-Platonists, the companions of his advancing years, appear here as his authorities, and throw into the background Locke and the empirical teachers of his youth. In *Siris* he traces the steps by which, at the dawn of the Christian era, Greek and Greco-oriental speculation sought to rise towards the Infinite and Ineffable, and to connect the sensible world and the embodied spirits of men in an intellectual unity in the Divine Reason.

The beautiful home-life at Cloyne ended in 1752, when declining health hastened the execution of a long-formed project to resign his episcopate and make Oxford the home of his old age. Six months after he had reached Oxford, on the 14th of January 1753, he suddenly passed from the world of sense. His body was buried in the cathedral of Christ Church.

Berkeley's life has been one of the principal forces in modern philosophy. His thought has indeed been for the most part only unconsciously operative, beneath the shock and sense of strangeness with which, interpreted as an absurd paradox, it has been popularly received. But it is at the root of all the great conflicts of ultimate speculation about the universe in the 18th and 19th centuries. David Hume, looking only at what Berkeley denied, so misapplied the 'new principle' as to disintegrate spirit as well as matter into a succession of isolated feelings; although Berkeley had really resolved even matter, not into isolated feelings, but into a continuous presentation of significant sense phenomena. Reid and the Scottish psychologists were roused to attempt a deeper and truer psychology than Locke's by the desire to refute the Berkeley they saw in Hume. English and French empirical psychology, from Hartley and Condillac to John Stuart Mill and Comte, has accepted the phenomenalist theory of matter, but emptied of the originating and directing Reason which in Berkeley's thought was its philosophically necessary constitution. In Germany, Kant told that he was roused into philosophical criticism from his 'dogmatic slumber' by the metaphysical nescience which Hume had discovered in his one-sided Berkeley; and the Kantian criticism has formed the European thought of the 19th century, as Lockian psychology formed it in the 18th, and the dogmatic constructions of Cartesianism in the 17th. The abstract self-consciousness of Neo-Kantianism has a certain affinity with the Neo-Platonic idealism of *Siris*—not yet sublimated into Hegelian abstractness in Berkeley's concrete spiritualism, which recognises Reason as at once personal and supreme. It is thus a fact of history that Berkeley has employed the modern philosophical world in a struggle, virtually about his new conception of the universe, which has lasted for nearly two hundred years.

Berkeley's writings are collected in the Clarendon Press edition (4 vols. 1871; new ed. 1901), annotated, with prefaces, dissertations, and a Life by the author of this article, who also published *Selections from Berkeley* (1881; 5th ed. 1899), and two smaller works (1881-1909). See also Seth, *English Philosophers* (1912); Sorley, *History of English Philosophy* (1920); G. A. Johnston, *Development of Berkeley's Philosophy* (1923).

Berkeley Sound, next to Stanley Sound the most frequented inlet of East Falkland, near its north-eastern extremity. Though it is difficult to enter, yet it contains several excellent harbours.

Berkhampstead, GREAT, an urban district of Hertfordshire, on the small river Bulburn, 28 miles

NW. of London. There are manufactures of ladies' clothing, wooden articles, and chemicals. Berkhamstead is an educational centre. The poet Cowper was a native. Pop. 7300.

Berkovitz, the chief town of a district in western Bulgaria, 40 miles NNW. of Sofia, on a small tributary of the Danube; pop. 6000.

Berkshire, a midland county of England, bounded N. by Gloucester, Oxford, and Bucks, E. by Oxford and Bucks, SE. by Surrey, S. by Hampshire, and W. by Wiltshire. Its greatest length is 53 miles; its greatest breadth is 30; and the area is 725 sq. m., or 463,830 acres, nearly one-half of which is under tillage, one-fourth in pasture, and one-sixteenth in wood. Berkshire, which is one of the most beautiful of the English counties, lies in the valley of the Thames, and has an undulating surface, rising in some parts into hills. Solid chalk underlies the whole area. A range of chalk-hills, or downs, connected with the Chilterns on the east and the Marlborough Downs on the west, crosses the county into Wiltshire, from Reading to Wallingford, attaining at White Horse Hill (so called from the gigantic figure of a horse rudely defined in the chalk—a relic of ancient times) a height of 893 feet. Between this range—the west part of which is occupied by sheep-walks—and a smaller oolitic one skirting the valley of the Thames, is the Vale of the White Horse, the richest part of the county, and drained by the Ock. To the south of the Downs is the fertile Vale of Kennet, drained by the river of that name, and its feeder, the Lambourn. To the east is the forest district, comprising Windsor Forest, part of Bagshot Heath, &c. The forest chiefly consists of hazel, oak, beech, ash, and alder. The Thames skirts the whole north border of the county, winding through a course of 100 miles, but in a direct line only 52, and navigable nearly the whole way. It is the chief river of Berkshire, the other rivers of the county being its tributaries; of which the chief are the Kennet, Loddon, and Ock. The Kennet is navigable for 30 miles. The climate of Berkshire is very healthy, being mild in the valleys, and bracing on the high lands. The soil varies greatly; in the valleys it is generally a fertile loam, with a subsoil of chalk, gravel, or clay. The country between the valleys of Kennet and the White Horse consists chiefly of sheep-walks; and along the Thames, and to the west of the Ridge Way, or Downs, it is chiefly dairy and pasture land. The chief crops are oats and wheat. 'Double Gloucester' and 'pine-apple' cheese are sent in large quantities to London. Swine are extensively reared, especially near Faringdon, the breed being one of the best in England. Property is very much divided, and the number of gentlemen's seats is very great. The farms are generally of moderate size. The county is traversed by the Great Western Railway and its branch lines, and by two canals. It returns three members to parliament, one for each of the three divisions (Abingdon, Newbury, Windsor), besides one for the county borough of Reading (the county town). Till the Redistribution of Seats Act of 1885, the boroughs of Wallingford and Abingdon also elected members, and till 1918 Windsor. The county contains besides these the municipal boroughs of Wokingham, Newbury, and Maidenhead, the urban district of Wantage, and the market-towns of Faringdon, Hungerford, East Ilsley, and Lambourn. The chief manufactures are noticed under READING. The British and Roman remains are numerous, including Roman roads, and many camps and barrows. Of the old castles, the principal is Windsor; of monastic establishments, the abbeys of Abingdon and Reading. The churches

are small, and, from the scarcity of building-stone, are often constructed of chalk and flint. There are many Norman churches, erected in the 12th and 13th centuries. In 1836 Berkshire was transferred from the diocese of Salisbury to that of Oxford. Pop. (1801) 110,480; (1911) 271,009; (1921) 294,807. See Vincent's *Highways and Byways in Berkshire* (1907), and the 'Victoria History' (1906 *et seq.*).

Berlad (Rumanian *Bârladu*), a town of Lower Moldavia, on the Berlad River, 40 miles above its junction with the Sereth. It is an important place, connected with Braila by rail, and has a brisk trade. Pop. 25,000.

Berlen'gas, a group of rocky islands in the Atlantic Ocean, off the west coast of the Portuguese province of Estremadura.

Berlichingen, GOTZ VON. See GOTZ.

Berlin, the capital of Prussia, and, since 1871, of the German reich (as empire and as republic), the seat of the German Reichstag and Prussian Landtag, and the largest city of continental Europe, is situated on the Spree, in 52° 30' N. lat., 13° 24' E. long. The city is built upon a flat sandy plain, which, though cultivated, is far from being fertile. Its average height above the level of the Baltic is only 100 feet, and its mean temperature is 48° F. The Spree, here about 200 feet wide, with a current so sluggish as scarcely to be perceptible, flows from SE. to NW. through the city, dividing it into two nearly equal parts, and communicating with the Oder and the Baltic by canals. The inconvenience of its low-lying situation in the midst of the sandy flats of Brandenburg is more than made up for by the great geographical advantages of its position in the heart of northern Germany, Berlin being half-way from Hamburg to Breslau, from Stettin to Leipzig, and from Memel to Alsace, from the mountains of central Germany to the Baltic, and within convenient distance of the frontiers of Poland and Holland. The advance of the city has been extraordinary. In 1804 the pop. was 182,157; in 1858 it was 438,961; in 1871 it was 826,341 (including 20,565 soldiers); in 1880, 1,122,330; and in 1885, 1,315,287, the city covering at that date an area of 15,500 acres, and measuring about 6 miles across. In 1900 it had 1,888,848 inhabitants; in 1910, 2,071,257. War had reduced the population to 1,902,509 in 1919. In 1920, however, seven suburban towns and a number of other districts were formed with Berlin into a single commune, with an area of over 877.6 square kilometres and a population (1919) of 3,803,901. Berlin thereby became a city of slightly greater area than New York, or nearly three times that of the county of London, stretching to, but not including, Potsdam. The towns absorbed in 1920 were Charlottenburg, Neukölln, Berlin-Schöneberg, Berlin-Lichtenberg, Berlin-Wilmersdorf, Spandau, and Cöpenick.

As far back as the 13th century the central part of the present city was inhabited. *Kölln*, on the island formed by the Spree on its left bank, was united to *Old Berlin* on the right bank in 1307. These names are still retained by the corresponding quarters of the modern city. The Wendish *köllen* means 'a hill rising above water or swampy ground,' and *Berlin* is most probably to be traced to the root of *wehr* (English *weir*), 'a dam in a river.' Berlin was long little more than a fishing-village; it was not till the 'Great Elector,' Frederick-William (1640–88), had united the separate duchies of which Prussia is now formed that the town became of consequence as the capital of a large state. In the next century it received accessions of French and Bohemian colonists, driven into

exile by religious persecution. Every inducement was then held out to bring foreigners to settle in the rising city. Under Frederick the Great it continued to prosper. At his death the inhabitants numbered 145,000. After the peace of 1815 Berlin increased with extraordinary rapidity, and, being the seat of government, a focus of the arts and sciences, and a great centre of commercial enterprise, it has gradually risen to a position which fairly entitles it to its present rank as the metropolis of the German republic.

The centre of the city is now devoted almost exclusively to commerce. The bulk of the houses are built of brick, plastered or stuccoed outside. Before 1864 most of them were of one, two, or three stories, but these fast gave way to houses of a larger size. The increase in the value of house-property was enormous. Berlin contains a large number of very fine buildings. At the centre of the city is the former royal palace, with nearly 700 apartments, including the richly adorned state-rooms, the finest of which are the magnificent 'Weisser Saal' and the palace chapel. Near this are the palaces which were occupied by William I. and by Frederick III. as crown prince; the old and new museums, the national gallery, the arsenal, the theatre, the opera-house, the guard-house, and the university. These are all situated between the Spree and the east end of the street 'Unter den Linden' (so called from its double avenue of limes, not unmixd with other trees), one of the finest streets in Europe, about a mile long, and almost 150 feet broad. The Prussian State Library (which has over 1,750,000 volumes and 50,000 MSS.) was in 1914 (as the Royal Library) removed from this neighbourhood to a building on the north side of Unter den Linden, in which are housed also the University Library and the Academy of Sciences. A continuation of Unter den Linden, beyond the Opernplatz, Lustgarten, and Kaiser-wilhelmsbrücke, cuts through the old town on the other side of the Spree. The other chief streets are Friedrichstrasse (2 miles long), Leipzigerstrasse, Königstrasse, and Wilhelmstrasse, in which are the president's palace, which formerly housed the ministry of the royal house, and the chancellor's, where the Congress of Berlin sat in 1878. The city is adorned throughout with numerous statues of national heroes, the statue of the Great Elector and the equestrian statue of Frederick the Great being the most remarkable. There are more than 20 theatres in Berlin. Berlin has numerous classical and other gymnasia, higher boys' and higher girls' schools, middle and elementary schools. The university, though only established in 1809, has taken a distinguished place among the universities of the world. Among its professors have been Fichte, Hegel, Schelling, Schleiermacher, Eichhorn, De Wette, Wolf, the Grimms, Niebuhr, Savigny, Neander, Bopp, Ranke, Curtius, Lepsius, Mommsen, Dörner, Virchow, Du Bois-Reymond, Helmholz, Hofmann, Sybel, Van't Hoff, Harnack, Treitschke, Fischer, Einstein. The number of professors and lecturers is now about 600, and of students about 12,000. It possesses a large library. Of other institutions may be mentioned the Academy of Sciences, by far the most important of the kind in Germany; the Military Academy; the Academy of Architecture; the Academic High School (of art); the School of Mines; the School of Agriculture; the Technical and Engineering Colleges; the Industrial (1881), Ethnological (1886), and other museums; the Academy of Music; the Observatory; many scientific and learned societies; several seminaries for teachers and missionaries; and a large number of public and private institutions and societies for benevolent purposes. Of the numer-

ous hospitals in Berlin, the Charité (adjoining which is the Pathological Institute, long guided by Virchow) is the largest in Germany. About 88 per cent. of the population are Protestants, 7 per cent. Roman Catholics, and 5 per cent. Jews. The cathedral was rebuilt in 1893-95. Of other Protestant and Catholic churches, the Nicolaikirche (restored in 1880), Marienkirche (with a spire 295 feet high), and Klosterkirche, all of the 13th century, are the oldest; the Petrikirche (with a tower 315 feet high) is the loftiest; and the Michaelskirche (Catholic), Thomaskirche, Zionskirche, Dankeskirche, and Heilige-Kreuzkirche are among the finest. The Synagogue (1866) has a richly decorated interior, a gilded dome 158 feet high, and seats for 3000 persons.

The Old Museum includes antiquarian objects, a great collection of coins, a gallery of ancient sculpture, and an extensive picture-gallery. The New Museum contains six magnificent mural paintings by Kaulbach in the grand staircase, a very extensive and valuable collection of casts, the Egyptian museum, and a fine and very numerous collection of engravings. The National Gallery contains works by modern artists, and the Kaiser Friedrich Museum a fine collection of old masters. The celebrated Brandenburg Gate (erected in imitation of the Propylæa at Athens, 65 feet high and 205 feet wide) leads from Unter den Linden and the Pariser Platz to the Tiergarten, a park of 370 acres (with the monument of Friedrich-Wilhelm III., and those of Goethe and Queen Luise, both erected in 1880). South-west of this lies the Zoological Garden, now considerably extended. The Botanical Garden is at Schöneberg. Noteworthy also are the Rauch Museum in the Lagerhaus (the oldest secular building in the city), the Rathaus, the Aquarium, the eight marble groups on the Schlossbrücke, the château of Monbijou (with the Hohenzollern Museum), the Ruhmeshalle in the arsenal (beautifully rebuilt in 1883), the monuments of Stein, of Calvin, of Schiller (before the theatre), and of the Humboldts (in front of the university), the Gothic monument on the Kreuzberg, the Column of Peace in the Belle-Alliance-Platz, the Warriors' Monument, and the Column of Victory, 200 feet high, erected in the Königsplatz in commemoration of the great victories of 1864, 1866, and 1870-71, near which are the War Office and the Reichstag building (the latter, with four towers and a cupola, built in 1884-94), and Reinhardt's Grosses Schauspielhaus by Polzig.

The commerce and manufactures of Berlin have increased so rapidly that it now ranks among the most important mercantile places of continental Europe. The traffic is carried on by the Spree, the canals, and railways, of which the intra-mural or 'city railway,' opened in 1882, passes through the middle of the city from east to west, and the suburban or 'ring railway,' 23 miles long, forms a complete circle round its outskirts. The geographical position of Berlin makes it a great emporium for agricultural products coming from East Prussia, Russia, and central Europe. The traffic by water is much greater than that of any other inland town of Germany. The staple commodities are grain, cattle, spirits, timber, coal, and wool. The Exchange is the centre of the North German money-market. The Reichsbank is the chief bank in Germany for the issue of notes. The principal branches of industry are woollen-weaving, calico-printing, and the manufacture of engines and other machinery, also of iron, steel, and bronze wares, drapery goods, and confections. Berlin has also very important manufactures of railway and other carriages, sewing-machines, safes, telegraphic apparatus, scientific instruments, chronometers, steel pens, and jewellery. Of the other industries of

Berlin the chief are its manufactures of pianofortes, accordions (of which it is the main source of supply for the foreign trade), and other musical instruments; hardware, German silver, lamps, and metal toys; leather, paper, rubber, soap, and chemicals; furniture, carpets, porcelain, and other earthenware; gloves, linen articles, straw-hats, and artificial flowers. Great quantities of beer are brewed. There were in 1900 some 5000 factories of all kinds, employing over 175,000 persons. In respect of its publishing trade, Berlin now shares with Leipzig the first rank amongst German cities. Formerly the sanitary condition of Berlin was very bad; the river was polluted, and open drains ran through the streets. But since 1870 the corporation has spent freely on public health, and Berlin municipal arrangements have become a model to many other cities. Still nominally part of Brandenburg, Berlin is virtually a province, the only link left being the common Oberpräsident. The governing body (since 1920) consists of thirty salaried members, with an Oberbürgermeister, and an assembly of 225 members. For local purposes there are twenty municipalities, each with its own governing body.

See the articles CHARLOTTENBURG, SPANDAU, &c.; J. Pollard, *A Study of Municipal Government: The Corporation of Berlin* (1894); and books on Berlin by Vize-telly (London, 1879), Ring (1883), Friedel (1883), Baedeker (new ed. 1923), Borrmann (1892), Lampe (1909), and Goldschmidt (1910).

THE CONGRESS OF BERLIN met at Berlin in June 1878, and consisted of representatives of Russia, Turkey, Germany, Great Britain, France, Austria-Hungary, and Italy. It was primarily designed to revise the preliminary treaty of San Stefano, concluded by Russia and Turkey after the war of 1877-78, and the treaty of Berlin began a new era in the history of the Ottoman empire. Rumania, Serbia, and Montenegro were recognised as independent, the latter states receiving additional territory. The concession of additional territory to Greece was recommended (and made, 1881). Rumania received the Dobruja in compensation for Bessarabia, given to Russia. Ardahan, Kais, Batum, and other parts of Armenia were ceded to Russia by Turkey. Turkey engaged to carry out reform in Asia Minor and Crete. Bulgaria became an autonomous but tributary principality, and Eastern Rumelia (which was practically united to Bulgaria after the war with Serbia in 1885), though remaining under the direct political and military authority of the sultan, secured administrative autonomy and the right to have a Christian governor-general. Bosnia and Herzegovina were to be occupied and administered by Austria-Hungary. Prince Bismarck was president of the Congress, and the Earl of Beaconsfield and the Marquis of Salisbury were the English plenipotentiaries.

Berlin, or KITCHENER, a town of Ontario, Canada, 62 miles SW. of Toronto by rail; pop. 15,200.

Berlin, (1) a city of New Hampshire, on the Androscoggin River, 98 miles by rail NW. of Portland, has manufactures of paper, pulp, and lumber, for which it uses the water-power of Berlin Falls; pop. 16,000.—(2) A city of Wisconsin, on the Fox River, 97 miles by rail NNW. of Milwaukee, has extensive industries; pop. 4400.

Berlin, ISAAH (1725-99), a Breslau rabbi, a critical student of the Talmud.

Berlin, JOHANN DANIEL (1710-75) composer, born at Memel, was organist at Trondjem.

Berlin Decree. See CONTINENTAL SYSTEM.

Berlinghieri, ANDREA VACCA (1772-1826),

surgeon, born at Pisa, lectured on surgery there, and wrote on lithotomy, &c.

Berlin Spirit, a coarse whisky made chiefly from beet-root, potatoes, &c. Because of its cheapness it has been largely used in the making of brandy, and in fortifying cheap unwholesome wines. The effect upon the consumer is pernicious. See BRANDY, DISTILLATION, WINE.

Berlioz, HECTOR, a musical composer of remarkable but eccentric genius, was born December 11, 1803, at Côte-St-André, in the department of Isère, France, where his father was a physician. Against the wishes of his parents, who intended him to pursue the same profession, and sent him to Paris to study medicine, he devoted himself to music, entering the Conservatoire as a pupil of Lesueur. Amid severe privations—for his father had cut off his supplies—Berlioz continued his musical education, winning the second prize in 1828, and the first, or *Grand prix de Rome*, in 1830, with a cantata entitled *Sardanapalus*. In accordance with the conditions attached to this prize, Berlioz now went to Italy, where he resided for upwards of a year, and became acquainted with Liszt and Mendelssohn. The artistic surroundings of his life in Rome, however, were profoundly distasteful to him, and his sojourn was not marked by much creative work. After his return to Paris, in the year 1832, Berlioz soon brought some of his compositions to a hearing; but their complicated and peculiar nature failed to win popular recognition, and Berlioz was driven to support himself and his wife—he married the Irish actress, Henrietta Smithson, in 1833—by writing musical criticisms for various newspapers, an irksome burden from which he only freed himself at the close of his life. In this work, often wrung from him with the utmost pain and effort, are revealed those remarkable gifts of style, of picturesque expression, and of humour, which render his letters and his memoirs such admirable reading. When occasion offered, Berlioz also adopted the precarious livelihood of a concert-giver. In 1838 Paganini was so much impressed by a performance of the *Symphonie Fantastique* that he presented, or became the medium for presenting, Berlioz with the sum of 20,000 francs. In 1842 he set out on the first of those foreign concert tours which more than anything else indemnified him for the indifference of his compatriots. More than once he was offered a post in Germany, but could not make up his mind to tear himself away from Paris. In the course of these journeys Berlioz visited and was received with almost uniform enthusiasm in Belgium, Germany, Austria, Bohemia, Hungary, and Russia. In 1848 he was engaged by Jullien as conductor at Drury Lane, but the enterprise proved a disastrous failure. In 1855 he fulfilled another engagement in London as conductor of the New Philharmonic Society. It is pleasant to think that Berlioz, who was much attached to England, and had a profound veneration for Shakespeare, has owed the posthumous rehabilitation of his fame chiefly to the efforts of musicians resident in that country. Sir Charles Hallé, a friend of Berlioz's earlier years, produced his *Damnation de Faust* at Manchester in 1880, since which time it has made its way into the *répertoire* of all the chief choral societies of the kingdom; and Sir A. Manns, at the famous Saturday concerts of the Crystal Palace, was equally assiduous in familiarising English audiences with the colossal masterpieces of the French composer. Between 1855 and 1869, in which year Berlioz died, the course of his life presents no special features. He had practically abandoned composition, the only

work produced in this period being his opera *Les Troyens*, performed with moderate success in 1863. The complete list of Berlioz's works is comprised within the limits of twenty-six *opus*-numbers; but this scanty array affords no clue to the magnitude of their dimensions. After his *Faust*, which is, perhaps, deservedly his most popular work, his most successful achievements are his symphonies, *Roméo et Juliette*, *Harold en Italie*, and the *Symphonie Fantastique*; his overtures, *Carnaval Romain*, *Benvenuto Cellini*, and *Waverley*; his charming opera, *Beatrice et Bénédicte*; his sacred trilogy, *L'Enfance du Christ*; and finally, his great *Messe des Morts*—the requiem written for the obsequies of General Damrémont in 1837—and his *Te Deum*, in the *Judez* of which Berlioz rises to his greatest height. A great deal of Berlioz's best literary work is buried in the files of the *Débats*; but his published writings amount to several volumes, including his *Soirées d'orchestre*, *A travers Chants*, *Les Grotesques de la Musique*, his *Mémoires* (published in 1865), and finally, his well-known treatise on orchestration, which has been translated into English, and is a standard work on the subject. The characteristics of Berlioz's compositions are too remarkable to be discussed in a brief summary. His conceptions were grandiose rather than great, and in carrying them out he sometimes narrowly escaped an abrupt lapse from sublimity to bathos. He delighted overmuch in extravagantly exciting effects; but his sense of orchestration was so abnormally acute that, as an English critic has observed, no matter what the effect was, it was sure to sound exactly as he intended it. In delicate orchestral embroidery he stands alone—witness the 'Queen Mab' scherzo in his *Roméo et Juliette*, and the accompaniment to the chorus of spirits of the air in *Lélio*. Though accused of being a revolutionary in music, he entertained the most touching and enthusiastic reverence for Beethoven, Weber, and Gluck. Of an imperious and uncompromising disposition in his official and professional relations, he was nevertheless on terms of close intimacy with a great number of his contemporaries, amongst whom may be mentioned Liszt, Heine, Balzac, Stephen Heller, and Ernst. Schumann at once recognised his great talent, and published eulogistic analyses of his works in the *Neue Zeitschrift für Musik*. Berlioz was made a chevalier of the Legion of Honour in 1839, and was elected a member of the Institute at Paris in 1856. He died 8th March 1869.

See the books on Berlioz (pronounced *Ber-le-ze*) by Jullien (1888), Hippeau (1883 and 1892), Pohl (1884), Thompson (1895), Tiersot (1904), and Lives compiled from his own Letters and Memoirs by the Misses Holmes (1884), Mainwaring Dunstan (1882), and Miss Boulton (1904).

Bermondsey, on the south bank of the Thames, is a metropolitan and parliamentary borough; pop. 119,000. See LONDON.

Bermuda, or SOMERS' ISLANDS, a British possession in Mid-Atlantic, so named respectively from Bermudes, a Spaniard, who first sighted the islands in 1515, and from Sir George Somers, an Englishman, whose shipwreck here in 1609 was the immediate occasion of their being colonised from Virginia—itself only four years old—in 1611. This low and lonely archipelago is a mere group of specks; for though it numbers perhaps 100 islets and more than twice that number of rocks, yet it measures only about 12,000 acres in all, the whole occupying a space of about 14 miles in length by little more than 5 in breadth. The islands are composed of blown coral sand, and are surrounded by a living, growing reef of coral, the whole being

a modified Atoll (q.v.), and the most northerly of such structures. The great value of this natural fortress as a British naval station, defended by its extensive barrier of reefs and rocks, with only one or two intricate channels, arises from its situation. In 32° 15' N. lat., and 64° 51' W. long., the Bermudas occupy, commercially and politically, a singularly commanding position. At a distance of 580 miles from Cape Hatteras, in North Carolina, they are about equally remote from the north of Maine and from the south of Florida; while they are a connecting link between Canada and the British West Indies. In the principal or Main Island is situated the present seat of government, Hamilton, on a deep inlet running 2 or 3 miles into the land. St George's, the island next in importance, contains the picturesque town of the same name, and a land-locked harbour, the entrance to which is defended by strong batteries. Ireland

Island is entirely occupied by H.M. Dockyard and other naval establishments; and Boaz and Watford Islands have the military depôts and garrisons. The famous Floating Dock towed from England in 1869 (381 feet x 124 feet) was superseded by a new one (545 feet x 100 feet), without gates, towed out in 1902, capable of dealing with cruisers like the *Terrible* and ships like the *Campana* (see DOCK). The minor islands of St David, Cooper, Smith, Nonsuch, Godet, and others, form numerous picturesque creeks and bays of great size and depth, such as the Great Sound, Castle Harbour, Harrington Sound, and others. Most of the other islands are insignificant, many of them without name or inhabitant. The group forms an almost continuous chain, and, with one break, there is uninterrupted communication by roads, causeways, and bridges for a distance of about 22 miles; but from the strange shapes of most of the islands, and the number of spacious lagoons, the communications are almost as necessarily by water as are those of Venice. The climate is tempered by an almost constant sea-breeze, and the air is moist at all seasons. The thermometer never falls below 40° F., and seldom rises above 85°. The annual rainfall is 52 or 53 inches. The islands are becoming a popular holiday and winter resort, especially for Americans; and both Hamilton and St George's are plentifully supplied with hotels and shops. The climate, however, is not suited for consumptive invalids. The soil is poor in quality, and not more than a third is cultivable at all; but there being no winter frosts, crops can be prepared for March, April, May, or June, and the large quantities of early potatoes, onions, tomatoes, and other garden vegetables, which in these months fetch high prices at the New York markets, enable the Bermudians to live comfortably on the income of their comparatively small portions of ground.

Sweet potatoes, arrowroot, and bananas are also largely grown; and the islands produce vast numbers of lily-bulbs, which are shipped to the United States, and kept in hot-houses till they can be planted out later. The fisheries are productive. Almost all the export produce goes to the United States and to Canada, and thence the food-supplies of the islands (grain, flour, rice, live-stock, &c.) are mainly supplied. There is frequent steam communication with New York. Bermuda is an important naval base, with dockyard and victualling establishments. The population, only 12,150 in 1871, had by 1920 (not including the garrison) increased to about 22,000, of whom only 7500 were whites. Till 1862 Bermuda was a convict station. The islands received representative institutions by royal charter in 1627, and are under the authority of a governor and executive council of 6 members appointed by the crown; a legislative council of 9 members also appointed by the crown; and an assembly of 36, four of whom are elected by each of the nine parishes. Hamilton (pop. 2600) and St George's have each a mayor, aldermen, and councillors. St George's has developed as a bunkering port. In September 1899 an unusually severe cyclone visited the 'still vexed Bermoothes'—of which Bermuda is now the accepted spelling. More than half of the population belong to the Church of England, under the Bishop of Newfoundland and Bermuda.

See works on Bermuda by Lefroy (1882), Ogilvy (1883), Dorr (1884), Stark (1884), Hailprn (1890), Newton (1897), Bell (1902), and Hayward (1923); the colonial reports; and the annual local guide and directory.

Bermudez, a state in the NE. of Venezuela, between the Orinoco and the Caribbean Sea, formed in 1881 from the states of Barcelona, Cumana, and Maturin. It was broken up in 1901, reconstituted in 1904, and again broken up in 1909.

Bermudez, LAKE, an asphalt lake in north-eastern Venezuela, some 30 miles from the coast, is approached by ships by the Gulf of Paria and the San Juan River. It is about 3 square miles in area, much shallower (at least where it has been worked) than the Trinidad lake, is richer in bitumen, and is more covered with water, mud, and vegetation.

Bern, or **BERNE**, a Swiss canton, bounded on the N. by France. It is the most populous, and next to the Grisons the most extensive, its area being over 2650 sq. m., and its population 674,000—more than one-sixth of the Swiss people. About 11 per cent. are Roman Catholics. The fertile valleys of the Aar and the Emmenthal divide the mountainous Alpine region in the south from the Jura Mountains in the north. The Bernese Oberland, or Highlands, comprises the peaks of the Jungfrau, Monch, Eiger, Schreckhorn, Finsteraarhorn, &c., and the valleys of Hasli, Lauterbrunnen, &c. The lakes of Thun, Brienz, Neuchâtel, and Bienne are in the canton, which is watered by the Aar and its several tributaries. The climate is generally healthy. The plains of the Aar and the Emmenthal are the most fruitful, producing corn and fruits of various kinds, and affording excellent pasturage for cattle, which, with dairy-produce, form the chief agricultural wealth of Bern. The vine grows in some districts. The horses of the Emmenthal are much prized. The lakes abound with salmon and trout. Iron-mines are worked, and a little gold is found, and quarries of sandstone, granite, and marble are abundant. Its manufactures, which are not extensive, consist chiefly of linen, coarse woollens, leather, iron, and copper wares, articles of wood, and watches. Bern entered the Swiss Confederation, in which it now holds the second rank, in 1352. In the 15th and 16th centuries, it

added to its possessions Aargau and Vaud, which it lost during the wars of the first Napoleon; but it received in return Bienne and its territory, and the greater part of the bishopric of Basel. The present constitution of the canton, proclaimed in 1874, but based on the laws of 1848, is one of representative democracy.

Bern, or **BERNE**, capital of the above canton and of Switzerland, is situated on a lofty sandstone promontory formed by the winding Aar, which surrounds it on three sides, and is crossed by several bridges, one of which is an imposing iron structure of 1883, 751 feet long, and 115 high. Bern is 68 miles by rail SSW. of Basel. It is one of the best and most regularly built towns in Europe, as it is the finest in Switzerland. The houses are massive structures of freestone, resting upon arcades, which are lined with shops, and furnish covered walks on both sides of the street. Rills of water flow through the streets. The view of the Alpine peaks from the city is magnificent. The principal public buildings are a Gothic cathedral (1421-1573), whose restoration and completion was undertaken in 1887; the magnificent Federal Council Hall (1857), the mint, the hospital, and the university. Bern has an interesting museum and a valuable public library. The manufacturing industry is trifling, and consists chiefly of dress fabrics and hats; but there is a considerable trade in the produce of the surrounding district. Population, 105,000. Bern was founded in 1191, was made a free imperial city in 1218, under Frederick II., and gradually extended its possessions until it became an independent state; and between 1288 and 1339 successfully resisted the attacks of Rudolf of Hapsburg, Albert his son, and Louis of Bavaria. The 'Disputation of Bern' between Catholics and Reformers in 1528 (January 6-27) prepared the way for the acceptance of the reformed doctrine. Bern is the residence of foreign ministers, and, since 1849, the permanent seat of the Swiss government and diet. On account of the traditional derivation of its name (old Swabian *bern*, 'a bear'), bears have for several centuries been maintained in Bern, and the bear-pit is still one of the 'sights' of the city. For the Bern Convention, see COPYRIGHT. For Dietrich of Bern (that is, Verona, not Bern in Switzerland), see THEODORIC.

Bernadotte, the French Napoleonic officer who became king of Sweden as Charles XIV. (q.v.).

Bernard, GREAT ST. See ST BERNARD.

Bernard, CLAUDE, a great French physiologist, born at Saint-Julien, near Villefranche, 12th July 1813. He studied medicine at Paris, became a hospital-surgeon in 1839, and two years later assistant at the Collège de France to the great physiologist Magendie, with whom he worked for thirteen years, until his own appointment in February 1854 to the chair of General Physiology. The same year he was chosen member of the Academy of Sciences, and in 1855 he succeeded to Magendie's chair of Experimental Physiology. Bernard was elected to the Academy in 1868, and died at Paris, February 10, 1878. His funeral was conducted at the public expense, an honour never before given to a man of science, and his *éloge* at the Academy fell to Renan. As an original investigator, Bernard stands among the foremost of the century. His earliest researches were devoted to the physiological action of the various secretions of the alimentary canal. His proof that the sole use of the pancreatic juice in the digestive system is so to modify the ingested fats as to render them capable of being absorbed by the chyle ducts, is a masterpiece of biological demonstration. Another important discovery established the saccharine function of the

liver. Still more important was his demonstration of the connection between this function of the liver and the nervous system. He showed that the normal formation of sugar in the liver could be totally interrupted by severing the pneumogastric nerve in the neighbourhood of the heart, and moreover, that by a wound made on the floor of the fourth ventricle of the brain, an abnormal formation of sugar could be immediately induced—a great contribution to our knowledge of the pathology of diabetes. For these great discoveries Bernard received the physiological prizes of the French Academy in 1851 and in 1853. Later researches were on the change of temperature of the blood in its passage from one organ to another; on the absorption of oxygen by the blood, and the respective amount of it in arterial and in red and black venous blood; on the comparative properties of the opium alkaloids; on the poisonous properties of curarine; and on the sympathetic nerves in general; as well as numerous investigations on the individual processes in the act of digestion. The great experimentalist was a remarkably lucid lecturer, alike in the academic chair and on the platform, and his *Leçons de Physiologie Expérimentale appliquée à la Médecine* (1865) is a standard work far beyond his country. Other books are: *Leçons sur les Effets des Substances Toxiques et Médicamenteuses* (1857), *Introduction à l'Étude de la Médecine Expérimentale* (1865), and *Leçons de Pathologie Expérimentale* (1874). Many of his papers appear in the special scientific journals, and in the *comptes rendus* of the Académie des Sciences and the Société de Biologie, of which last he was a founder and president. See the Life by Sir Michael Foster (1899).

Bernard, St. of Clairvaux, one of the most influential theologians of the middle ages, was born of a noble family at Fontaines, near Dijon, in Burgundy, in 1091; entered the Cistercian monastery of Cîteaux at twenty-two; and became two years later the first abbot of the newly-founded monastery of Clairvaux, in Champagne. He died at Clairvaux, August 20, 1153; and was canonised by Pope Alexander III. in 1174. His ascetic life, solitary studies, and stirring eloquence made him during his lifetime the oracle of Christendom. He founded more than seventy monasteries, and his persuasive earnestness was such that he drew also into the monastic life both his two elder and his two younger brothers, while we are told that mothers hid their sons, wives their husbands, companions their friends, that they might escape the resistless spell of his spiritual enthusiasm. He was honoured with the title of the 'mellifluous doctor,' and he is regarded by the Catholic church as the last of the fathers. Bernard drew up the statutes of the Knights Templars at the request of their grandmaster in 1128. The reverence in which he was held gave him great influence in the political movements of his time. It was due to his persuasion that Innocent II. was recognised at the Synod of Étampes (1131) by Louis VI. of France, soon after by Henry I. of England and the Emperor Lothar of Germany, as pope in opposition to the antipope Anacletus. His influence in Christendom rose to its height under the reign of Pope Eugenius III., his disciple. It was his glowing eloquence at the council at Vézelay in 1146 that kindled the enthusiasm of France for the second crusade. Charged by the pope to excite the religious zeal of the people of France and Germany, Bernard accomplished his mission with fatally memorable success. Fields, towns, cities, and castles were in many places almost depopulated, and thousands of men, fired by his prophetic eloquence, hurried to the East, but few of whom were ever to see their homes again.

The influence of St Bernard as a spiritual teacher through his fervid piety and living grasp of Christian doctrine was a wholesome antidote to the dry and cold scholasticism which prevailed among the churchmen of his age. 'If there ever lived on the earth a God-fearing and holy monk,' says Luther, 'it was St Bernard of Clairvaux.' Yet his Christianity lacked the perfect flower of gentleness, and he was harsh and severe in judging heretics like Abelard. His writings consist of more than 400 epistles, 340 sermons, and 12 distinct theological treatises, edited by Mabillon (Paris, 6 vols., 1667-90), and in Migne's *Patrologia Latina* (4 vols., 1851-52). His life of St Malachy is of special interest to Britons. It is doubtful if 'Jesus, the very thought of thee,' and some other hymns attributed to him, were really his. The hospice and pass of St Bernard (q.v.) are not named after him. The monks of the reformed branch of the Cistercians, reformed by him, are often called, in France, Bernardines. He gave name also in Fiance to the nuns of the Cistercian order, which his sister, St Humbeline, is said to have founded. See lives by Cotter Morison (3d ed. 1877), Ratisbonne, Mabillon, Eales, Storrs (1893), Vacandard (1895), Sparrow Simpson (1895), and Halusa (1898); the letters translated by Cardinal Gasquet (1904); Coulton, *Five Centuries of Religion* (i. 1923).

Bernard, St. of Menthon, founder of the hospice of St Bernard (q.v.).

Bernard of MORLAIX, a monk of Cluny about 1140, is said to have been born of English parents at Morlaix in Brittany. He is the author of the remarkable poem *De Contemptu Mundi*, in 3000 long rolling, 'leonine-dactylic' verses, which has been freely translated by Dr Neale as *The Rhythm of Bernard of Morlaix*. From this 'Jerusalem the Golden' and other well-known hymns are taken.

Bernardin de St Pierre. See ST PIERRE.

Bernardines. See CISTERCIANS.

Bernardino, St., of Siena, born in 1380 at Massa-Carrara, of a distinguished family, made himself famous by his rigid restoration of their primitive rule amongst the degenerate order of the Franciscans, of which he became a member in 1404. In 1438 he was appointed vicar-general of his order for Italy. Bernardino was unweariedly devoted in his activity during the great Italian plague of 1400, both as an impressive preacher and an attendant upon the sick and dying. He founded the *Frates de Observantia*, a branch of the Franciscan order, which already numbered more than 300 monasteries in Italy during his day. Bernardino died in 1444, and was canonised in 1450. His works were eminently mystical. See a Life of him by Thureau-Dangin (translated 1912).

Bernauer, AGNES, the beautiful daughter of a poor surgeon of Augsburg, secretly married, in 1432, to Duke Albrecht of Bavaria, only son of the reigning Duke Ernst. Their happiness was undisturbed, till Albrecht's father, becoming aware of his son's attachment, had the knightly lists shut against him, as one who was living with a woman in licentiousness. Albrecht now made Agnes be openly honoured as Duchess of Bavaria. But in her husband's absence, Duke Ernst had Agnes tried for sorcery, condemned for having bewitched Albrecht, and drowned in the Danube in the presence of the whole people, October 12, 1435. Albrecht took up arms against his father; but after a year of war he was prevailed on to return to his father's court, and ultimately consented to marry Anna of Brunswick.

Bernay, a French town in the department of Eure, 25 miles WNW. of Évreux. One of the

largest horse-fairs in France is held here annually. Pop. 6000.

Bernays, JAKOB, an eminent philologist, born of Jewish parents at Hamburg in 1824, made his studies at Bonn, where he became professor and librarian in 1866, and died, May 26, 1881. Among his numerous books were a *Life of Scaliger* (1855), *Lucian und der Cyniker* (1879), an edition of *Lucretius* (1852), and a translation of three books of Aristotle's *Politics* (1872). His *Gesammelte Abhandlungen* were edited by Usener (1885).

Bernburg, a town in the German land of Anhalt, till 1863 capital of Anhalt-Bernburg, lies on the Saale, 23 miles S. of Magdeburg. Bernburg has manufactures of machinery, sugar, spirits, porcelain, paper, and starch. Pop. 33,000.

Berne. See BERN.

Berners, or BARNES, DAME JULIANA, a writer on hunting and hawking, of whom almost nothing is really known. Tradition has it that she was prioress of Sopwell Nunnery, near St Albans, and daughter of Sir James Berners, who was beheaded in 1388. To her has been generally conceded the authorship of the *Treatyse petykyngye to Hawkyngge, Huntynge, and Fysshynge with an Angle*; also a right noble *Treatyse on the Lynage of Coote Armuris*; *endynge with a Treatyse which specifyeth of Blasynge of Armys*; although she probably wrote only the treatise on hunting, and part of that on hawking. The heraldry is certainly not hers. The earliest extant edition, printed at St Albans in 1486, is issued without the treatise on fishing. A facsimile of this with an introduction by William Blades appeared in 1881. A folio edition was printed by Wynkyn de Worde in 1496, and at least ten more editions appeared before 1600, a testimony to the popularity of the 'Boke of St Albans.' A facsimile was issued by Haslewood in 1810, discussing how far she was the first woman-writer in English. An edition of the *Fysshynge* was printed by Baskerville in 1827, and another in 1880. —For Lord Berners, see FROISSART.

Bernese Oberland. See BERN.

Bernhard, Duke of Weimar, a celebrated German general, born in 1604, was the youngest of the eight sons of John, third Duke of Saxe-Weimar. On the outbreak of the Thirty Years' War, he took the side of Protestantism, and first distinguished himself in 1622 at the bloody battle of Wimpfen. Subsequently, he became colonel in the army of Christian IV. of Denmark. In 1631 Gustavus Adolphus made his appearance in Germany, and Bernhard was one of the first who flew to his standard. He commanded the left wing at Lützen, and after the king's death had the chief command. He took a very important part in the war; but after a brilliant career, he fell suddenly ill, and died at Neuburg on the Rhine, July 8, 1639. Bernhard's own opinion, and that of others, that he died of poison administered by his physician, who is supposed to have been in the pay of Richelieu, is not supported by evidence. See Droysen, *Bernhard von Weimar* (Leip. 1885).

Bernhardt, ROSINE, called SARAH, a French actress, born of Jewish parents in Paris, October 22, 1844, was baptised into the Christian faith by her father's desire, and brought up in a convent at Versailles. Entering the Paris Conservatoire in 1858, she gained second prizes for both tragedy and comedy, and in 1862 made her début as 'Iphigénie' at the Théâtre Français, but attracted so little notice that she soon left the theatre, only to meet with still less success in burlesque at the Gymnase and Porte St Martin. In 1867 she played minor parts at the Odéon, and became famous by her impersonation of the 'Queen of Spain' in *Ruy Blas*,

and of 'Zanetto' in Coppée's *Passant*. She was recalled to the Théâtre Français in 1872, and after 1879 made annual appearances, with marked success, in London. Her tours in North and South America, in Italy, Russia, &c., were also pecuniarily successful; but her essay at the management of a Paris theatre involved her in heavy debt. In 1882 she was married to M. Jacques Daria or d'Amala, a Greek actor, from whom she was divorced shortly afterwards. Madame Bernhardt, probably the greatest *tragédienne* since Rachel, and in comedy also a finished actress, wrote a drama (*Adrienne Lecouvreur*, 1905), and paintings and statues from her studio appeared in the Salon. She died March 1923. See her *Reminiscences* (trans. 1907).

Bernhardy, GOTTFRIED, a German scholar, born of Jewish parents near Frankfort in 1800, was educated at Berlin, and in 1829 became director of the philological seminary at Halle. Here he died, May 14, 1875. Of his numerous philological works may be mentioned his *Syntax der griechischen Sprache* (1829); *Paralipomena Syntaxis Græcæ* (1854); and the critical edition of *Suidæ Lexicon* (4 vols. 1834-53). His works on Roman and Greek literature, especially the history of the latter, are also of high value.

Berni (also *Bernia*), FRANCESCO, a favourite Italian poet, from whom comic or jocose poetry has the name of *Versi Berneschi*, was born at Lamporecchio, in Tuscany, about 1496. He first entered the service of his uncle, Cardinal Bibbiena, and was afterwards for several years secretary to Ghiberti, chancellor to Clement VII. About 1530 he betook himself to Florence, where he was made a canon, and lived in favour with the two Medici, Duke Alessandro and Cardinal Ippolito, till his death in 1536, which, however, according to another story, was brought about by the former, in consequence of Berni's refusal to poison the cardinal. His *Opere Burlesche* are to be found in the *Classici Italiani* (Milan, 1806). His recast or rifacimento of Boiardo's *Orlando Innamorato* was received with such favour that it was thrice reprinted from 1541-45; it is still read in Italy (and justly so) in preference to the original. He had a large share in establishing Italian as a literary language. A full account of Berni is given in his *Life* (Florence, 1882) by Virgili, who has also published a volume of his lyrics, letters, and Latin verses (1885).

Bernicia, a Latinised form of the British word *Bryneich*, used to indicate the northern part of what became the kingdom of Northumbria, the part north of the Tees. The Anglian kingdom of Bernicia is said to have been founded by Ida, who made his capital at Bamborough about 550 A.D. See NORTHUMBRIA.

Bernier, FRANÇOIS, a French physician and traveller, famous alike as a philosopher and a wit, was born at Angers, in France, and departed for the East about 1654. He visited Syria, Egypt, Arabia, and India, in the last of which countries he resided for twelve years in the capacity of physician to Aurungzebe, and on his return to France he published a delightful account of his travels in 1670-71. Bernier died at Paris in 1688.

Bernina, a mountain of the Rhaetian Alps, 13,290 feet high, in the Swiss canton of Grisons, with remarkable and extensive glaciers. Its summit was first attained in 1850. The Bernina Pass, which attains an elevation of 7642 feet, and over which run a carriage-road and a railway, leads from Pontresina to Poschiavo.

Bernini, GIOVANNI LORENZO, sculptor, architect, and painter, was born at Naples in 1598. He early devoted himself to sculpture, and in his

eighteenth year finished his admired group of Apollo and Daphne, which gave promise of greater excellence than was afterwards realised by the artist. Pope Urban VIII. employed him to produce designs for the embellishment of St Peter's at Rome, and his greatest achievement in architecture is its colossal colonnade. In 1663 he accepted the flattering invitation of Louis XIV., and travelled to Paris with great pomp. In Paris he resided above eight months; but his design for the Louvre being deemed inferior to Perrault's, he confined himself entirely to sculpture. His visit, however, proved a highly remunerative one. Richly laden with gifts, he returned to Rome, where he died, November 28, 1680, leaving a fortune of £100,000 to his children. Besides his works in sculpture, Bernini also left numerous paintings behind him. Few artists have been so much admired and rewarded during their lifetime as Bernini; but the triumphs of his art are now mostly regarded as absurdities.

Bernoulli, or **BERNOULLI**, was the name of a family that produced a succession of men who became famous over all Europe for the successful cultivation and extension of various branches of mathematical and physical science. The family originally resided in Antwerp, whence, in 1583, its attachment to the reformed religion drove it to seek an asylum in Frankfurt. Afterwards the Bernoullis settled in Basel, where they achieved the highest professional honours. Eight of them became highly distinguished; but special mention can be made here only of the three most celebrated—James, John, and Daniel.

JAMES BERNOULLI was born at Basel, December 27, 1654, where he also died, August 16, 1705. He devoted his life to the study of mathematics, of which, in 1687, he became professor in the university of Basel, succeeding in that chair the distinguished Megerlin. His *Conamen Novi Systematis Cometaurum*, an essay on comets, suggested by the appearance of the comet of 1680, and his essay *De Gravitate Aetheris*, both showed the influence of Descartes' philosophy. Besides a variety of memoirs on scientific subjects, he published no other work of importance. *De Arte Conjectandi* was a posthumous work concerning the extension of the doctrine of probabilities to moral, political, and economical subjects. His collected works were published in 2 vols. 4to, at Geneva, in 1744. Among his triumphs are to be recorded his solution of Leibnitz's problem of the isochronous curve, and his determination of the catenary. At his request, a logarithmic spiral was engraved on his tomb, with the motto, *Eadem mutata resurgo*.

JOHN BERNOULLI, brother of the preceding, was born at Basel, July 27, 1667. He and James were the first two foreigners honoured by being elected associates of the Academy of Sciences at Paris, and they were also made members of the Academy of Berlin. John devoted himself to chemical as well as to mathematical science. In 1694 he took the degree of M.D., and soon after became professor of Mathematics at Groningen, whence he only removed to succeed his brother James in the university of Basel. His forte was pure mathematics, in which he had no superior in Europe in his day. He died January 1, 1748. The determination of the 'line of swiftest descent,' and the invention of the 'exponential calculus,' have been claimed as his achievements. His collected works were published at Geneva, in 4 vols. (1742).

DANIEL BERNOULLI, born at Groningen, February 9, 1700, died at Basel, March 17, 1782, was the second son of John. Like his father, he devoted himself to medicine as well as to mathematics. The family reputation early helped him to the professorship of Mathematics at St Petersburg,

whence he withdrew to Basel and occupied chairs of Anatomy and Botany and of Experimental and Speculative Philosophy. He wrote mainly on pneumatics and hydrodynamics.

Beroaldo, **FILIPPO** (1483–1505), born at Bologna, and a professor of classics at the university there, forwarded the cause of humanism by his lectures and his editions of Latin authors.

Berœ, one of the commonest representatives of the most intensely active sub-class of Coelenterates—the Ctenophora (q.v.). These are free-swimming pelagic animals, of great delicacy and beauty, generally of a more or less cylindrical form, and without any trace of skeleton, which indeed rarely occurs in the more active lower animals. Beroe is the type of a small family, Beroidæ, in which the body is oval or spherical, but slightly flattened in one plane. They are transparent, and often beautifully coloured, especially during reproductive periods. The lower pole is occupied by the large mouth, which leads into a spacious and complex alimentary canal ending at the top. The superior pole bears a complex sensory organ, and between the two are eight meridional bands, each bearing a row of comb-like plates formed from the union of cilia. These ciliary plates move very rapidly, producing a beautiful iridescence, and wafting the beroe through the water in any desired direction. It has been shown that the limy 'otocyst,' which forms part of the sense organ, may act as an automatic balancing and steering apparatus. Like many other active marine animals, the Ctenophora are phosphorescent, and beroe is one of the most brilliant examples. The light shines out especially from the regions of the meridional bands. The beroes are very voracious, feeding on small crustaceans and the like, but with a marked preference for their own relatives. They are themselves swallowed in shoals by whales. During the day they descend to deeper water, but come to the surface at night. In autumn they seem to frequent the surface more constantly, and may then be observed in great crowds. The distribution of the genus, which includes three certain species, is very wide, and one form is quite common on British coasts. Beroe differs most markedly from related forms, such as Cydippe, Pleurobrachia, &c., in the absence of a pair of long tentacles. See CTENOPHORA.

Bero'sus, or **BEROSSUS**, a priest of Babylon, who had a knowledge of Greek, and flourished about 260 B.C. He wrote, in Greek, three books of Babylonian-Chaldean history, in which he made use of the archives in the temple of Bel at Babylon. The work was highly esteemed by Greek and Roman historians, but unfortunately only a few fragments have been preserved by Josephus, Eusebius, and Syncellus; even these are of great value, as they relate to the most obscure portions of Asiatic history. They have been edited by W. Richter (Leip. 1825), and Muller, in the second volume of *Historicorum Græcorum Fragmenta* of the 'Collection Didot' (Paris, 1848). The *Antiquitatum Libri Quinque cum Commentariis Joannis Anni*, first published in Latin by Eucharius Silber (Rome, 1498) as a work of Berosus, and often republished, was the pseudonymous work of the Dominican, Giovanni Nanni of Viterbo. See BABYLONIA.

Berre, **ÉTANG DE**, an extensive lagoon of France, department Bouches-du-Rhône, about 45 miles in circumference, with large salt-works and eel-fisheries.

Berri, or **BERRY**, formerly a province of Central France, now forming the departments of Indre and Cher. Having come, in 1160, into the possession of the French crown, it was raised to a duchy in 1360, and gave title at various times to French

princes, the younger son of Charles X. being the last who held it.

Berri, CHARLES FERDINAND, DUC DE, second son of the Count of Artois (afterwards Charles X.), was born at Versailles, January 24, 1778. In 1792 he fled with his father to Turin; fought with him under Condé against France; afterwards visited Russia, and lived for some time in London and Edinburgh. In 1814 he returned to France, and the following year was appointed by Louis XVIII. commander of the troops in and around Paris. In 1816 he married Caroline Ferdinande Louise (born 1798), eldest daughter of Francis, afterwards king of the Two Sicilies—a marriage on which depended the continuance of the elder Bourbon line. The duke was assassinated on 13th February 1820, as he was conducting his wife from the Opera-house to her carriage, by a fanatic named Louvel. He left only a daughter, born 1819; but on 29th September 1820, the widowed duchess gave birth to the Comte de Chambord (q.v.). After the July revolution, 1830, in which the duchess exhibited immense force of character and courage, offering herself to lead on the troops against the insurgents, she, with her son, followed Charles X. to Holyrood, but left a considerable party in France in favour of the pretensions of her son as Henry V. During a visit to Italy, she was so far encouraged in her ambition, that a project was formed for reinstating the Bourbons; and, accompanied by several friends, she landed near Marseilles, April 29, 1832. After many adventures, she was betrayed by a Jew at Nantes, and was imprisoned in the citadel of Blaye. The confession of the duchess, that she had formed a second marriage with the Neapolitan marquis, Lucchesi-Palli, at once destroyed her political importance, and the government set her at liberty. She died in Styria, 16th April 1870.

See works by Ménière (1882), Imbert de St Amand (1890; trans. 1893), and H. Noel Williams (1911)

Berry (*Bacca*), a term employed in popular language to designate almost any small succulent fruit, but restricted in botanical language to simple fruits with pericarp succulent throughout, whether developed from superior (grape, potato, bitternut, belladonna, bryony, asparagus, tomato), or more commonly inferior ovary (gooseberry, currant, barberry, bilberry, &c.). Strawberry, raspberry, blackberry, mulberry, yewberry, &c. are thus all excluded from the definition, for the first is an expanded succulent axis, bearing the true fruits as dry nutlets; and the second and third are an aggregation or *asterio* of drupes (corresponding in fact, save for their origin from a single flower, to a bunch of cherries). The mulberry arises from the union of a crowded cluster of separate female flowers of which the fruit of each is an achene, the pulp belonging to the calyx, while the red berry-like pulp of the yew fruit is a subsequent upgrowth or *Aril* (q.v.).—The orange and other fruits of the same family, having a thick rind dotted with numerous oil-glands, and quite distinct from the pulp of the fruit, receives the name *hesperidium*; the fruit of the pomegranate, which is very peculiar in the manner of its division into cells, is also sometimes distinguished from berries of the ordinary structure by the name *balausta* (see POMEGRANATE). Fruits which, like that of the water-lily, are at first juicy, and afterwards, when ripe, are dry, are sometimes designated *berry-capsules*. Fruits of the gourd family (*Cucurbitaceae*) are commonly distinguished under the name of *pepo*, but, at anyrate when the rind as well as the pulp is soft at maturity, are true berries.

Berryer, PIERRE ANTOINE, a distinguished French advocate and political orator, was born in Paris, 4th January 1790, and first distinguished

himself by his brilliant defence of Lammennais in 1826, and Chateaubriand in 1833. In 1829 he was chosen deputy, and ever afterwards steadily represented the rights and policy of the elder Bourbons. His legitimist tendencies kept him for a time in the political background under Louis-Philippe; but as the legitimist party in the Chamber increased, his position grew in importance. He repeatedly undertook the defence of persons prosecuted by the government, not only of his own party, but republican leaders. It was he who defended Louis Napoleon, 1840, after the Boulogne escapade, as well as Montalembert afterwards in 1858. With the elder Bourbons he was in constant communication, and was one of the heads of the legitimist party who made a pilgrimage to the Count of Chambord in London in 1843. After the revolution of 1848, he represented the Bouches-du-Rhône; seemed inclined to support the government of the president, Louis Napoleon; and became a member of his privy-council. But this did not hinder him from going to Wiesbaden in 1850 to do homage to the Count of Chambord. He was one of the few who boldly protested against the *coup d'état*. In 1854 he was elected a member of the French Academy. His inaugural speech contained some uncomplimentary allusions to the emperor, and its publication was for a time prohibited. He died at his country seat near Paris, 29th November 1868. His *Discours Parlementaires* fill 5 vols. (1872-74); his *Plaidoyers*, 4 vols. (1875-78). His statue was erected in the Palace of Justice at Paris in 1879.

Bersaglie'ri (Ital., 'marksmen'), the riflemen or sharpshooters of the Italian army, first organised in the Sardinian army in 1836. Light active soldiers, wearing a picturesque but serviceable dark-green uniform, and hats with dark plumes of cock's feathers, they were prominent alike in the Crimea and in the struggles that resulted in Italian unity. Akin to them are the Alpini, a force of mountaineer sharpshooters, organised since 1876.

Ber'serker, a redoubtable hero in Scandinavian mythology, the grandson of the eight-handed Starkadder and the beautiful Alfhilde. By the daughter of King Swafurum, whom he had slain in battle, he had twelve sons, who inherited the name of Berserker, along with his frenzied, warlike fury or 'berserker-rage.' The name is also used as a general term for Scandinavian warriors of like temper. The etymology is doubtful. Probably the word means 'bear-sark' (or shirt), not 'bare-shirt.' It has been connected with the Werwolf (q.v.) superstition.

Bert, PAUL, French statesman and physiologist, was born at Auxerre in 1833. He studied both law and medicine, became assistant to Claude Bernard at the College of France, and successively occupied the chairs of Physiology at Bordeaux and Paris. Entering political life in 1870, on the proclamation of the Republic, he was four times re-elected to the Chamber. He brought forward laws removing primary instruction from the control of the religious orders, and making it compulsory. During the premiership of Gambetta he held the post of minister of public instruction and worship. While engaged in public life, M. Bert still pursued with ardour his scientific investigations, attracting world-wide attention by his experiments in vivisection. Appointed by the French Ministry to the governorship of Tonquin and Annam, he went out there in 1886, but died on 11th November of the same year. The anti-religious views of M. Bert excited much controversy. He was also the author of several works on anatomy and physiology, and of numerous educational and political writings. M.

Bert was a member of the French Academy of Sciences, and of many other distinguished bodies at home and abroad.

Bertha, the name of several famous women in the legendary history of the middle ages.—ST BERTHA, whose day is kept on the 4th July, a Frankish princess who married Æthelbert, king of Kent (560 A.D.), became the means of his conversion, and of the spread of Christianity among the Anglo-Saxons.—In the romances of the Charlemagne cycle, there figures a BERTHA, called also 'Bertrada with the Big Foot,' daughter of Count Charibert of Laon, wife of Pepin the Little, and mother of Charlemagne. Her whole personality is of a mythical nature, and has several of the attributes of the goddess Berchta.—In the romances of the *Round Table*, the name of a sister of Charlemagne, mother of Roland by Milo d'Anglesis.—Better known is BERTHA, wife of Rudolf II. (937), king of Burgundy beyond Jura, and afterwards of Huzo, king of Italy. See also BERCHTA.

Berthelot, PIERRE EUGENE MARCELLIN, an eminent French chemist, born at Paris, October 25, 1827, at an early age made a special study of acids and fermentation, and was appointed professor of Organic Chemistry in the École de Pharmacie in 1859, and in the Collège de France in 1861. In 1876 he was named inspector-general of education, in 1886-87 he was minister of public instruction, and in 1895 foreign minister. His labours to reproduce the substances which enter into the composition of organic bodies, besides opening up a new field of research, have directly benefited more than one industry. His early studies established the theory of polyatomic alcohols (see ALCOHOL), and he devoted much attention to explosives; whilst, more recently, his observations of the heat-phenomena which produce chemical combinations laid the foundation of thermochemistry. He died suddenly, 18th March 1907.

Among his works are *Chimie Organique* (1860), *La Poudre et les Matières Explosives* (1872), *La Synthèse Chimique* (3d ed. 1881), *Mécanique Chimique* (1879), *Les Origines de l'Alchimie* (1885), *Science et Philosophie* (1886), and *Science et Religion* (1897). And see the *Correspondance* between him and Renan (1898).

Berthier, ALEXANDRE, Prince of Neuchâtel and Wagram, was born at Versailles, February 20, 1753. A soldier's son, he entered the army in 1770, and fought with Lafayette in the American war of independence. In the French Revolution he soon rose to be chief of the staff in the army of Italy (1795), and in 1798 entered the papal territory, and proclaimed the republic in Rome. He accompanied Napoleon to Egypt in the same year as chief of the staff, a post which he also held in all the subsequent campaigns. At the revolution of 18th Brumaire (1799), he became war-minister, but continued to accompany the emperor on his campaigns. In 1807 he was made sovereign of the formerly Prussian principality of Neuchâtel, vice-constable, and imperial prince. In the campaigns of 1812, 1813, and 1814, he was constantly by the emperor's side, and acted both as chief of the staff and as quartermaster-general. On the fall of Napoleon, Berthier had to surrender the principality of Neuchâtel; and not to lose more, he submitted to Louis XVIII., who continued him his rank as peer and marshal. Napoleon made overtures to him from Elba; these he neither answered nor yet revealed to Louis, and this made him suspected by both. On the return of Napoleon from Elba, in a fit of irresolution Berthier retired to Bamberg, in Bavaria, to his father-in-law, Duke William. On 1st July 1815, as he looked from a window at a division of Russian troops marching towards the French frontier, the better sight was too much—he threw

himself down into the street, and thus ended his life. His *Mémoires* appeared in 1826.

Berthollet, COUNT CLAUDE LOUIS, one of the most distinguished theoretical chemists of his time, was born at Talloire, a village of Savoy, in 1748. He studied at Turin, and afterwards went to Paris. He now applied himself with great assiduity to chemistry; in 1781 he was elected a member of the Academy of Sciences. In 1785 he announced his adherence to the antiphlogistic doctrines of Lavoisier, whom he aided both in his researches on gunpowder and in the formation of a new chemical nomenclature. In the same year, Berthollet published a paper on 'dephlogisticated marine acid'—now called chlorine—pointing out its use for bleaching purposes; and following up the experiments of Priestley, he showed ammonia to be a compound of three volumes of hydrogen gas and one volume of nitrogen gas. During the early part of the French Revolution, he travelled through the country, giving instruction as to the process of smelting and converting iron into steel. He was made a senator by Bonaparte, who also made him a count. Notwithstanding, he voted for the deposition of Napoleon in 1814; and on the restoration of the Bourbons he was created a peer. He died at Arcueil, November 6, 1822.

Bertholletia. See BRAZIL NUTS.

Bertillon, ALPHONSE (1853-1914), criminologist, was born at Paris, and about 1885 worked out the 'Bertillon system,' now largely adopted in France and elsewhere, for identifying criminals by elaborate measurements of body, head, feet, and hands, which are carefully recorded for use upon occasion (see ANTHROPOMETRY, and his *Photographie Judiciaire*, 1890). In 1894 the system was introduced into Britain, being conjoined with Sir F. Galton's fingerprint method. He was the son of the anthropologist, Louis Adolphe Bertillon (1821-83).

Bertin, LOUIS FRANÇOIS (1766-1841), born in Paris, started the *Journal des Débats* in 1799. His royalist principles cost him imprisonment and banishment to Elba, but in 1805 he resumed the editorship of the *Débats*; and after the second restoration he gave almost constant support to the ministerial party, and to the July monarchy.—His son, ARMAND LOUIS MARIE BERTIN (1801-54), became secretary to Chateaubriand during his embassy in England, and succeeded his father on the *Journal des Débats*.

Bertram, C. J. See RICHARD OF CIRENCESTER.

Bertrand, HENRI GRATIEN, COUNT, one of Napoleon's generals, faithful to the last, was born at Châteauroux (1773), and early entered the armies of the Revolution as engineer. He accompanied the expedition to Egypt, and directed the fortification of Alexandria. He distinguished himself at Austerlitz, and became the emperor's adjutant; and, after the battle of Aspern in 1809, for his share in saving the French army by bridges, he was created count and governor of Illyria. After serving with credit in the subsequent campaigns, he retired with the emperor to Elba, was his confidant in carrying out his return to France, and finally shared his banishment to St Helena. On Napoleon's death, Bertrand returned to France, where, though sentence of death had been pronounced upon him—a sentence which Louis XVIII. had wisely recalled—he was restored to all his dignities, and in 1830 appointed commandant of the Polytechnic School. In 1840 he formed part of the expedition which brought back the remains of Napoleon to France. He died at Châteauroux, January 31, 1844.

Bervic, CHARLES CLÉMENT, engraver, born at Paris in 1756, in 1790 made himself famous by a full-length engraving of Louis XVI., from the

picture by Callet, one of the finest works of the kind ever produced. He died March 23, 1822.

Bervie, or **INVERBERVIE**, a parliamentary burgh and seaport in Kincardineshire, near the mouth of Bervie Water, 13 miles N.E. of Montrose by rail. It has flax and tow mills, and factories of wincey and sacking, and here in 1788 was set up the first machine for spinning yarn in Scotland. Pop. 1000.

Berwick, **JAMES FITZ-JAMES, DUKE OF**, was the natural son of James II., by Arabella Churchill, sister of the Duke of Marlborough. Born at Moulins in 1670, he was educated in France as a Catholic, and after serving in Hungary under Duke Charles of Lorraine (1687), returned to England shortly before the Revolution of 1688, which he exerted himself to prevent. The title Duke of Berwick was conferred on him in 1687. In 1689 he accompanied his father on his Irish expedition, and, after the death of St Ruth, had the nominal chief command. He next served in Flanders, under Marshal Luxembourg, and afterwards under the Duke of Burgundy and Marshal Villeroi. In 1706 he was created a marshal of France, and sent at the head of an army to Spain, where he established the throne of Philip V. by the decisive victory of Almansa. For this important service he was made a grandee of Spain, under the title of Duke of Liria and Xerica. After several years of comparative inactivity, he received the command in 1733 of an army intended to cross the Rhine. While besieging Philippsburg, he was killed by a cannon-ball, 12th June 1734. Contemporary testimony, confirmed by his military conduct, shows Berwick to have possessed some of the best qualities of a great commander. His defensive campaign in 1709, in Provence and Dauphiné, against the superior force of the Duke of Savoy, has always been regarded as a triumph of strategic skill. He was twice married. His son by the first marriage succeeded to the dukedom of Liria; whilst the dukedom of Fitz-James and the estates in France passed to his children by the second marriage. See his *Mémoires* (Paris, 1778); C. T. Wilson, *James II. and the Duke of Berwick* (1876); and his *Duke of Berwick, Marshal of France* (1883).

Berwick, NORTH. See **NORTH BERWICK.**

Berwick-on-Tweed, a seaport town at the mouth of the Tweed, on the frontiers of England and Scotland, 58 miles ESE. of Edinburgh, and 67 N. by W. of Newcastle. The liberties of the borough, called 'Berwick Bounds,' have an area of 8 sq. m., and with Spittal and Tweedmouth, form the 'county of the borough of Berwick-on-Tweed.' Though long boasting to be neither in England nor Scotland, and still possessing separate quarter-sessions and commission of the peace, it is to all intents and purposes part of the county of Northumberland (the adjoining parts of which formed till 1844 a detached portion of Durham); especially since by the Redistribution Act of 1885 Berwick-on-Tweed ceased to send two members of its own to parliament, and was for election purposes merged in Northumberland. The town is engirt with ramparts of Elizabeth's time, and fragments of Edward I.'s. Tweedmouth and Spittal (the latter a favourite watering-place), on the south side of the Tweed, have since 1835 both been included within the municipality of Berwick-on-Tweed. They are reached by a narrow stone bridge (1609-34) of fifteen arches; and the river is also spanned by Robert Stephenson's magnificent viaduct (1850) of 28 arches, 136 feet high and 2160 long. The public buildings include the town-hall (1760), with a belfry 150 feet high, the corn exchange (1858), and several churches, Presbyterian outnumbering the Anglican. The harbour has been improved by

the construction of a wet-dock (1873-76), at a cost of £40,000; but its trade is not very great, the tonnage of vessels entering during a twelvemonth ranging between 30,000 and 40,000. Nor is the salmon fishery what it once was. For the manufacture of agricultural implements Berwick-on-Tweed stands high, and in Spittal there are several large artificial-manure works. Pop. (1841) 12,689; (1881) 13,995; (1921) 12,994. The history of the town is full of interest, especially in regard to Border wars and the struggles of English and Scots to possess the town, the siege of Edward I. in 1296 being especially terrible. Its authentic records begin in the 12th century, when it was one of the principal seaports in the kingdom. It was annexed to England in 1333, after the battle of Halidon Hill, and was finally ceded by Scotland in 1482. See John Scott's *History of Berwick-on-Tweed* (Lond. 1888).

Berwickshire, a maritime and Border county of south-east Scotland, bounded N. by Haddington, N. and NE. by the German Ocean, SE. by Northumberland and Roxburghshire, and W. by Roxburghshire and Midlothian. It extends from east to west 29 miles, from north to south 21 miles, and has an area of 457 sq. m., or 292,535 acres. Berwickshire is divided naturally into three districts—the Merse, the Lammermoors, and Landerdale. The largest and most fertile district is the luxuriant valley of the Merse, the richest plain of equal extent in Scotland, being nearly 130,000 acres in area. The Lammermoors, covering 90,000 acres, chiefly pastoral, divide the valley of the Tweed from Midlothian and Haddington. Landerdale, comprising 67,000 acres, a mixture of hill and dale, runs along the banks of Leader Water. The coast, 19 miles in length, is rocky and bold, rising at St Abb's Head and other points to heights of from 177 to 528 feet above sea-level, and having only two bays, at Eyemouth and Coldingham. Geologically, as well as topographically, Berwickshire possesses numerous interesting features. The Lammermoors (q.v.), whose highest summit is Meikle Says Law (1749 feet), on the county boundary, and whose highest wholly in Berwickshire is Seenes Law (1683 feet), consist of Silurian strata, stretching to St Abb's Head. In the south Carboniferous rocks are found, while an extensive bed of Old Red Sandstone extends eastwards from the centre of the county to the sea-coast. On the coast porphyry is found, and some traps and syenite in the interior. Ironstone and thin seams of coal occur, as well as gypsum, clay, and shell-marl. The streams—Blackadder, Whitadder, and Leader Waters—are all tributaries of the Tweed, which runs along the southern boundary, the Eye alone flowing direct to the sea. Pop. (1801) 30,206; (1861) 36,613; (1891) 32,290; (1911) 29,643; (1921) 28,395. Berwickshire now unites with East Lothian to return one member to parliament. There are no parliamentary burghs in the county. Agriculturally, Berwickshire occupies a prominent position, two-thirds of the entire area being in cultivation. The Earliston gingshams excepted, there are no manufactures worth naming. The principal towns are Duns, the birthplace of Thomas Boston, Dr M'Crie, and, as some contend, of Duns Scotus; Greenlaw, the county town from 1696 till 1853, but gradually superseded by Duns; Lander, a royal burgh; Eyemouth, a prosperous fishing-station; Coldstream, where General Monk first raised the Coldstream Guards; and Earliston, the Erclidonne of Thomas the Rhymer. The county contains some very interesting examples, though on a comparatively small scale, of Norman or Pointed architecture, or both, at Coldingham, Dryburgh, Old Cambus, Edrom, Chirnside, Bunkle, Legerwood, and one or two other places. There are also the

remains or sites of Fast, Hume, and Cranshaws castles, and of British and Roman camps and barrows, besides remains of a curious broch-like structure at Edinshall, near Duns.

Beryl (silicate of alumina and glucina), a mineral which scarcely differs except in colour from Emerald (q.v.), never exhibiting the bright rich green which characterises that gem, but colourless, yellowish, greenish-yellow or blue. The finer varieties, which are transparent and of beautiful colour, are distinguished as Precious Beryl, and are sometimes called Aquamarine.

Beryl, in its primary form.

These occur in crystals similar in form to those of emerald; but the regular hexagonal prism is more frequently modified by truncation on the angles or edges, acumination, &c. The prisms are often long. Their sides are longitudinally striated, often deeply so; but the truncating or terminating planes are smooth. The coarser varieties of beryl (Common Beryl) are also found crystallised, but often massive. Beryl occurs chiefly in veins that traverse granite or gneiss, or in drusy cavities in granite; sometimes it occurs in alluvial soils formed from such rocks. Common beryl is found in a number of places in Europe. The mountains of Aberdeenshire, and those of Mourne in Ireland, yield precious beryl, which is also found in various parts of the United States, Brazil, Ceylon, and Siberia. It is somewhat less valuable than the emerald. For its use as a magic crystal, in which the future becomes visible, see Rossetti's *Rose Mary*.

Beryllium. See GLUCINUM.

Berzelius, JOHAN JAKOB, BARON, one of the founders of the science of chemistry, was born at a farm in East Gothland, Sweden, August 29, 1779. While studying for the medical profession at the university of Uppsala, he was more attracted by the preparatory studies in science, especially chemistry. After being some time employed in medical practice and lecturing, he was appointed (1806) lecturer on chemistry in the Military Academy of Stockholm, and, in the following year, professor of Medicine and Pharmacy. He was shortly after chosen president of the Stockholm Academy of Sciences; and from 1818 till his death, August 7, 1848, held the office of perpetual secretary. The king raised him to the rank of baron; other honours from learned societies were conferred on him, including the London Royal Society's gold medal. The field of his activity lay in his laboratory, where he acquired a name of which his country, where he ranks in science second only to Linnæus, is justly proud. The science of chemistry, as at present organised, rests in great measure upon the discoveries and views of Berzelius, although in not a few points he has been controverted or found wrong. His multiplied and accurate analyses established the laws of combination on an incontrovertible basis; and to him we owe the system of chemical symbols. He discovered the elements selenium, thorium, and cerium, and first exhibited calcium, barium, strontium, columbium or tantalum, silicon, and zirconium, in elementary form. Of his numerous writings, the most important was a text-book of chemistry (3 vols. 1808-18), which was translated into every European language.

Besançon, a French city, the capital now of the department of Doubs, and formerly of Franche-Comté, is picturesquely situated on both sides of the winding river Doubs, 57 miles E. of Dijon. It was strongly but irregularly fortified by Vauban, the citadel being perched on an inaccessible rock, 390 feet above the town. Since then, the fortifications have been extended and strengthened, and Besançon is now considered one of the strongest places in France. It was the ancient *Vesontio* or *Besontium*; in 58 B.C. Cæsar expelled the Sequani hence, and in the neighbourhood gained a victory over Ariovistus. It finally came into the possession of France in 1674. Several streets in Besançon still bear old Roman names; and in the neighbourhood are found ruins of a triumphal arch of Aurelian, an aqueduct, an amphitheatre, and a large theatre. Among later structures the 12th-century cathedral, the Madeleine church, the Prefecture, the Palais de Justice (1749), and the half-Gothic, half-Renaissance palace (1534) of Cardinal Granvelle, are most remarkable. Besançon makes a very large percentage of the watches made in France, and some 15,000 of its inhabitants are engaged in this industry, which was introduced from Switzerland about 1818. Other manufactures are porcelain, carpets, iron-wire, Seltzer-water, and beer. Abel Rémusat and Victor Hugo were natives. Pop. (1840) 36,461; (1886) 45,216; (1901) 55,266; (1911) 57,978; (1921) 55,652.

Besant, ANNIE, theosophist, was born in London of Irish parentage (her father William Page Wood) in 1847, and at twenty, a devout Anglican, married the Rev. Frank Besant of Sibsey, Lincolnshire. Having become a freethinker, and been legally separated from her husband in 1873, she joined the National Secular Society and was closely associated with Mr Bradlaugh (q.v.), the Fabian Society, and the Social Democratic Federation. In 1889, however, she became a devoted disciple of Mme. Blavatsky (q.v.); thenceforward at home and abroad, in the United States and in India, she laboured zealously in the cause of theosophy, publishing over a score of works, including an autobiography (1893), *Karma Dharma*, *The Wisdom of the Upanishads*, and *Esoteric Christianity* (1901). At Benares she founded the Central Hindu College, and a Hindu girls' school, on pure Hindu principles, and helped to found the Hindu University; but the Theosophic headquarters are at Adyar, Madras. Interned in 1917 for nationalist activities, she was in the same year chairman of the Indian National Congress. The article THEOSOPHY in this work is from her pen.

Besant, SIR WALTER, novelist, was born at Portsmouth in 1836, studied at King's College, London, and at Christ's College, Cambridge, and in 1861-67 was professor in the Royal College of Mauritius. He was knighted in 1895. His first work, *Studies in Early French Poetry*, appeared in 1868, and, in literary partnership with James Rice (q.v.), he produced *Ready-money Mortiboy* (1872); *My Little Girl*; *With Harp and Crown*; *This Son of Vulcan*; *The Golden Butterfly* (1876), which greatly increased the popularity of its authors; *The Monks of Thelema*; *By Celio's Arbour*; *The Chaplain of the Fleet*; and *The Seamy Side* (1881). After Rice's death, Besant wrote *All Sorts and Conditions of Men*, *The Captain's Room*, *All in a Garden Fair*, *Dorothy Forster*, *Children of Gibeah*, *The World went very well then*, *Beyond the Dreams of Avarice*, *The Master Craftsman* (1896), &c. He wrote also *French Humourists* (1873); short books on Rabelais, Coligny, and Whittington; a life of Professor Palmer (1883); a long series of works on London (1892-1912); and a number of articles for *Chambers's Encyclopædia*. He shows a first-

hand knowledge of very various phases of life, grasp of character, constructive skill, and humour at once shrewd and genial. The distinguishing feature of his novels is the interplay of ingenious fancy and thorough-going, healthy realism. His plots are sometimes as whimsical and charming as a fairy tale, while the setting of each story is worked out with scrupulous fidelity to local colour. In such a book as *All Sorts and Conditions of Men*, romance and realism are combined with the happiest results. Some of his later novels were written for the furtherance of social reforms, and the People's Palace, described in *All Sorts and Conditions of Men*, was carried into effect in the east end of London. His works on London and its history are partly by others. He was secretary of the Palestine Exploration Fund (1868-85), and first chairman of the committee of the Incorporated Society of Authors. He died 9th June 1901. See the library edition of *Ready-money Mortiboy* (1887), and his *Autobiography* (1902).

Besants'. See BEZANTS.

Besika Bay, a bay on the north-west coast of Asia Minor, opposite Tenedos, to the south of the entrance of the Dardanelles. The English fleet was stationed here during crises in the Eastern Question, in 1853-54 and 1877-78, and it was shelled in March 1915.

Bessarabia, a region of north-eastern Rumania, on the Ukrainian frontier. The area is 17,000 sq. m.; the population is about 2,400,000, composed of Rumanians, Russians, Poles, Bulgarians, Armenians, Jews, Germans, Swiss, and Tatars, with a sprinkling of Gipsies. The Dniester flows along the whole of its northern and eastern boundaries; the Pruth separates it from Moldavia on the west; and it has the Danube on the south. In the north-west the country is traversed by well-wooded offshoots of the Carpathian Mountains. Generally, however, Bessarabia is flat and fertile. The land is cultivated to some extent; but the breeding of cattle forms the chief business of the inhabitants. Salt, cattle, wool, and tallow are exported; leather, soap, and candles are manufactured. Bessarabia, which fell under the power of the Turks in 1503, suffered heavily in all wars with Russia, and was ceded to Russia in 1812. The portions lying along the Pruth and the Danube—3578 sq. m.—were by the Treaty of Paris assigned to Moldavia, but at the Berlin Congress of 1878 again transferred to Russia. In April 1918 the Bessarabian diet decided for union with Rumania.

Bessarion, JOHANNES (or *Basilius*), born at Trebizond, on the Black Sea, in 1395, was one of the earliest of those scholars who in the 15th century transplanted Greek literature and philosophy into the West, and rescued the mind of Christendom from the trammels of scholasticism. As Bishop of Nicæa, he accompanied the Greek emperor, John Palæologus, to Italy in 1439 in order to effect a union between the Greek and the Roman churches. Soon afterwards joining the Roman Church, he was made cardinal by Pope Eugene IV. Ten years later, Nicholas V. created him Bishop of Frascati. For five years also he discharged the duties of papal legate at Bologna. After the fall of Constantinople, of which he had been titular patriarch, he visited Germany, and endeavoured to promote a crusade against the Turks. In philosophy, he professed to be a follower of Plato, but without depreciation of Aristotle. Twice he was nearly elected pope. He died at Ravenna in 1472, leaving 600 valuable Greek MSS. to St Mark's Library at Venice.

Bessbrook, a town of County Armagh, 2 miles NW. of Newry; pop. 3400.

Bessèges, a town in the French department of Gard, 21 miles N. of Alais. It has coal, iron, and glass industries. Pop. 7000.

Bessel, FRIEDRICH WILHELM, an eminent Prussian astronomer, born at Minden in 1784. Successively a merchant's clerk, a supercargo on board ship, and a practical astronomer, he was in 1810 appointed director of the observatory at Königsberg, and professor of Astronomy there. In 1818 he published his *Fundamenta Astronomiæ*—a work which was of the highest value to astronomers; and in 1830 his *Tabulæ Regiomontaneæ*. Among the numerous papers may be mentioned his treatise on the precession of the equinoxes. After a series of three years' observations he succeeded in determining the annual parallax of the fixed star 61 Cygni (see STARS). In the years 1824-33 Bessel made a series of 75,011 observations in 536 sittings, and completed a catalogue of stars (extending to the ninth magnitude) within the zone from 15° N. to 15° S. declination; and published *Astronomische Untersuchungen* (1842) and other works. His *Popular Lectures on Astronomy* were published two years after his death, which took place March 14, 1846. He was a thoroughly practical man of science, was remarkable for the precision of his calculations, introduced many new methods, and greatly forwarded the science of astronomy.

Bessemer, SIR HENRY, F.R.S., inventor, born 19th January 1813, at Charlton, Herts, came of Huguenot stock. His father, Anthony Bessemer, born in London, was bred an engineer, and helped in the erection of the first steam pumping-engine set to work in Holland. Later he became eminent as a die-sinker and engraver in the Parisian mint, but was ruined by the Revolution, and retired to Charlton in Herts. His son Henry was trained by him at a small type-founding factory in Charlton, and in London worked at electrotyping, embossing, and die-sinking. He soon became a prolific inventor, and by a perforated die saved government £100,000 a year in frauds in respect of stamps. But this, like many of his inventions, was but poorly recompensed. His first pecuniary success was obtained by his invention of machinery for the manufacture of Bessemer gold and bronze powders, which was not patented, but whose nature was long kept secret. During the Crimean war he experimented in improving artillery, and to enable cannon to sustain the strain of discharging a projectile he had invented, experimented with a view to producing iron of greater strength. He came to think, in his own words, that 'if air could be brought into contact with a sufficiently extensive surface of molten crude iron the latter would rapidly be converted into malleable iron.' Patents were taken out in 1855, his 'converter' and apparatus were at work in London, and soon after he established a Bessemer steel works at Sheffield. The process is fully described in IRON AND STEEL, as also the importance of the development due to Mushet. The result was that, spite of great initial difficulties, the production of steel in England increased from less than 50,000 tons by the old processes in 1858 to over 2,000,000 in 1889. While the older (and finer) steel cost on an average not less than £50 a ton, Bessemer steel soon averaged £10. Great quantities of Bessemer steel are made in Germany and the United States. Bessemer was knighted in 1879, and in addition he had, to use his own words, received in the form of royalties 1,057,748 of the beautiful little gold medals issued by her Majesty's Mint. One of his unsuccessful inventions was a Channel boat with a saloon swinging freely so that it might, even in a heavy sea, be kept level and steady, and so save from the

pangs of sea-sickness. Such a boat was put on the cross-Channel service in 1875, but the mechanism was not found serviceable. Bessemer died 15th March 1898. See his Autobiography (1905).

Bessemer's name has been given to several towns in the United States. The most important is Bessemer in Jefferson County, Alabama, 11 miles SW. of Birmingham, in a country rich in iron and coal. The city, laid out in 1837 and incorporated in 1889, had in 1890 a population of 4544, in 1900 of 6358, in 1910 of 10,864, and in 1920 of 18,674. Iron and steel are largely produced, as also firebrick.—Another Bessemer is the county-seat of Gogebic, Michigan, 47 miles E. of Ashland in Wisconsin, and is engaged in iron-mining and manufacturing; pop. 5500.

Bessièrès, JEAN BAPTISTE, Duke of Istria, and Marshal of the French empire, was born of poor parents at Preissac, in the department of Lot, 6th August 1768. Entering the army in 1792 as a private soldier, in less than two years he had attained the rank of captain. After making the Spanish campaign he passed into the army of Italy, and soon attracted the notice of Napoleon, who carried him to Egypt in 1798, where his conduct at St Jean d'Acre and Aboukir covered him with glory. At the accession of Napoleon (1804) to the throne, he became marshal of France. He showed his usual conspicuous courage at Austerlitz, Jena, Eylau, and Friedland, and, raised to the rank of Duke of Istria, commanded in Spain in 1808-9. In the Russian campaign he led the cavalry of the Guard, and did much by his sleepless courage and presence of mind to save the wreck of the army in the disastrous retreat from Moscow. On the morning of the battle of Lützen (1st May 1813), he fell mortally wounded by a cannon-ball.

Best, WILLIAM THOMAS (1826-97), was born at Carlisle, the son of a solicitor, and was trained as an organist at the cathedral there. He held appointments at Liverpool in 1848-52, at London in 1852-54, and in 1855 returned to Liverpool to be organist of St George's Hall. He was also solo organist at the Handel Festivals. He composed many anthems, fugues, sonatas, and arrangements for the organ, and published two works on the organ and organ-playing.

Bestiary, the name given to a class of written books of great popularity in the middle ages, describing many animals, real and fabled, composed partly in prose, partly in verse, and generally illustrated by drawings. But they were valued for the moral allegories they contained, no less than as handbooks of zoological facts. The symbolism which was then so much in vogue fastened spiritual meanings upon the several animals, until every quality of good or evil in the soul of man had its type in the beast world. It is in this way to the bestiaries that we must look for explanation of the strange, grotesque creatures which are found sculptured on the churches and other buildings of the middle ages. The oldest Latin bestiaries had an early Greek original, the well-known *Physiologus*, under which name about fifty such allegories were grouped. The Greek text of this famous work is found only in late MSS. There are old Syriac, Armenian, Ethiopic, Arabic, Icelandic, and numerous Latin versions. Editions of the Latin have been issued—Mai, Heider, and Cahier. An Old High German version was made earlier than the 11th century; in the 12th century versions in French were made by Philippe de Thaun, Guillaume, a priest of Normandy, and Pierre, a priest of Picardy. Some Old English fragments have been edited by Grein and by Cook. The 13th century Bestiary in the South-east Midland dialect describes thirteen animals. One

section is founded on Neckam's *De Naturis Rerum*, the rest on the Latin *Physiologus* of Theobaldus, an Italian monk of the 11th century. The *Bestiaire d'Amour* of Richard de Fournival was rather a parody upon the earlier form of such books. The following is a characteristic extract from the *Bestiaire Divin*: 'The unicorn has but one horn in the middle of its forehead. It is the only animal that ventures to attack the elephant; and so sharp is the nail of its foot, that with one blow it rips up the belly of that most terrible of all beasts. The hunters can catch the unicorn only by placing a young virgin in the forest which it haunts. No sooner does this marvellous animal desery the damsel, than it runs towards her, lies down at her feet, and so suffers itself to be taken by the hunters. The unicorn represents our Lord Jesus Christ, who, taking our humanity upon him in the Virgin's womb, was betrayed by the wicked Jews, and delivered into the hands of Pilate. Its one horn signifies the gospel truth, that Christ is one with the Father,' &c. See *The Old English Physiologus* (text and prose translation by A. S. Cook, verse translation by I. H. Pitman, 1922).

Bestushev, ALEXANDER, a Russian novelist, born in 1795, was an officer in the guards, and became involved in the military conspiracy of 1825, in consequence of which he was degraded to the ranks, and exiled to Yakutsk. After long entreaty he was permitted to enter the army of the Caucasus as a private in 1830. In June 1837 he fell in a skirmish with the as yet unconquered mountaineers. His novels and sketches bore the impress of his own life and adventures in the Caucasus.

Bestushev-Ryumin, COUNT ALEXEI PETROVICH (1693-1768), was born at Moscow, but trained in Berlin, and by permission of Peter the Great entered the diplomatic service of the Elector of Hanover in 1713. He accompanied George I. to England in 1714, and remained there for some years. He served Peter faithfully as Russian minister at Copenhagen from 1822, became privy councillor to the Empress Anna, and under Elizabeth became vice-chancellor of Russia, practically controlling Russian policy for many years, hostility to Frederick the Great and alliance with Austria being his main principles of action. His recall of Apraxin caused him to be imprisoned on a charge of treason and condemned to death. Elizabeth remitted the death penalty, but he was deprived of all his dignities and exiled from court. The Empress Catharine II. recalled him, made him field-marshal, and relied on his advice for years.—His elder brother, COUNT MIKHAIL PETROVICH (1688-1760), was Russian ambassador at Stockholm, and for twenty years controlled the delicate relations between Russia and Sweden. After 1741 he, now a marshal, undertook embassies to Prussia, Poland, Austria, and France.

Bestushev-Ryumin, KONSTANTIN NIKOLAEVICH (1829-97), born in Novgorod province, studied law at Moscow, worked as a journalist in 1859-62, and from 1862 was professor of Russian history at Petersburg university. He translated Buckle into Russian, wrote much on history, and was author of a great *History of Russia* (vols. i. and ii. 1872-85; vol. iii. unfinished).

Betanzos (anciently *Brigantium Flavium*), a town of Spain, 10 miles SE. of Coruña; pop. 10,000.

Betel, properly the leaf of the betel-vine, a plant (*Piper betle*) of the natural order Piperaceæ, indigenous to the East Indian Archipelago, and cultivated also in continental India, Ceylon, and several of the Indo-Chinese countries (Burma, Siam, &c.), but more or less as

an exotic according as the necessary conditions of humidity and heat have to be artificially increased. The name betel (a Malayalam and Tamil word for 'leaf') is frequently applied to the bolus of areca-nut and shell-lime (*chunam*) wrapped round with betel-leaf, employed as a masticatory throughout a large part of the farther East, especially by the Malay and Hindu races. As early as Fryer (1673) betel begins to be used erroneously as a synonym for the nut of the Areca (q.v.) palm. Betel-leaf (Hindustani, *pán* or *pawn*; Persian, *tambul*; Malay, *sirih*) is described in glowing terms in the *Hítópadesa*, book iii., fable 9. The ancient Hindu writers recommend it to be taken early in the morning after meals, and at bedtime. Pills against phlegm are rubbed into an emulsion with the juice; and the leaves are applied to remove headache, reduce swollen glands, or check the secretion of milk. The use of the masticatory has become a matter of etiquette, and the betel-box plays as important a part as the snuff-box did in England in the 18th century. In India the offering of *pawn* by the host intimates the termination of a visit. Among the Malays of the Archipelago to offer *sirih* is accepted as a legal sign of apology for a serious offence. Europeans seldom take kindly to the habit of chewing betel,

Betel-vine.

partly because it blackens the teeth and causes the lips to appear as if covered with blood. Sir James Emerson Tennent (*Ceylon*) considers that it supplies the antacid, the tonic, and the carminative required by a people who usually eat no flesh. In former days the betel-leaf was a monopoly of the East India Company. The cultivation of the plant is in many districts a highly important industry, and requires considerable capital. In Bombay, betel-vines are put down in October, 3600 to 5000 per acre. They are sheltered from drought by plantains grown along with them, and by bamboo stages covered with grass. These are afterwards replaced by stronger and taller trellis-work up which the plants climb luxuriantly. In Tenasserim, again, the Karens train the vines to forest-trees from which all but the topmost boughs have been lopped off.

Betel-nut. See ARECA.

Betham-Edwards. See EDWARDS.

Beth'any ('house of dates'), by the natives of Palestine called 'El' Azariyeh' or 'Lazariyeh'

('town of Lazarus'), is situated on the southern slope of the Mount of Olives, 2208 feet above the sea, 2 miles ESE. of Jerusalem. It was the home of Lazarus and his sisters, often visited by the Saviour, and the scene of his ascension. Ecclesiastical buildings were erected here in the 4th century, but it is now a poor place of some 200 inhabitants. There is nothing remarkable about the village except the reputed house of Martha and Mary, and the cave or grave of Lazarus shown by the monks. Major Conder thinks it more likely that the tomb of Lazarus is one of the rock-cut sepulchres beside the Jericho road, east of Bethany.—Bethany is also the name that has been given to three German mission stations in South Africa; one in Great Namaqualand, one in the Orange Free State, and one in the Transvaal.

Beth'el ('house of God'), now called Beitin, about 11 miles N. from Jerusalem, mentioned in Scripture as the scene of Jacob's dream. The old name of the place was Luz. Here Abraham pitched his tent; at a later date it was a resting-place of the ark, a royal residence, and a seat of idolatrous worship. It is a heap of ruins.

Bethes'da, POOL OF ('house of mercy' or 'house of the stream'), the scene of Christ's cure of the impotent man (St John, v. 2-9), the tank that was the resort of the 'impotent, blind, halt, and withered.' Since 1102 it has been identified with the Birket Israil, which is situated within the walls of Jerusalem, near the St Stephen's gate and the Temple of Omar. Conder, however, identified it with the spring in the Kedron Valley called Gihon and En Rogel, which was diverted through a rock-cut tunnel to Siloam. But Schick in 1889 discovered the remains of the substructures of the pool near the church of St Anne.

Bethesda is a small town of Carnarvonshire (so named from its Nonconformist chapel), 4½ miles SE. of Bangor. Its 4000 inhabitants are mostly employed in the neighbouring Penrhyn slate-quarries.

Bethlehem ('house of bread'; modern *Beit-lahm*), the birthplace of Jesus Christ and of King David, and the Ephratah of the history of Jacob, is now a small unwall'd village of white stone houses, in the midst of a most interesting country, 6 miles S. of Jerusalem. The population, about 3000 souls, is wholly Christian—Latin, Greek, and Armenian. The Convent of the Nativity, a large square building, resembling a fortress, was built by the Empress Helena, 327 A.D., but destroyed by the Moslems in 1236, and, it is supposed, restored by the Crusaders. Within it is the Church of the Nativity, which is subdivided among the Latins, Greeks, and Armenians, for devotional purposes. The church is built in the form of a cross; the nave, which is by far the finest part of the building, belongs to the Armenians, and is supported by 48 beautiful Corinthian columns of solid granite, each between 2 and 3 feet in thickness, and about 17 in height. The other portions of the church, forming the arms of the cross, are walled up. At the farther end of that section, which forms the head of the cross, and on the threshold, is a sculptured marble star, which the Bethlehmites say covers the central point of the earth. Here a long intricate passage descends to the crypt below, where the blessed Virgin is said to have been delivered. The walls of the chamber are hung with draperies of the gayest colours; and a silver star, with the words, '*Ecce de virgine Maria Jesus Christus natus est*,' marks the spot of the nativity. The manger stands in a low recess cut in the rock. The site appears to have been venerated since the

2d century A.D., and St Jerome, a monk of this convent towards the end of the 4th century, found the grotto in possession of pagans, who celebrated here the birth of Adonis. To the north-west stands

than a hostile invasion, and on arriving under the walls of Presburg, was greeted with acclamations by the citizens. He was subsequently crowned king of Hungary by the assembled diet, August 25,

Bethlehem.
(From a Photograph by Frith.)

a square domed building, marking the reputed site of Rachel's tomb. The Bethlehemites chiefly gain their subsistence by the manufacture and sale of crucifixes, beads, boxes, shells, &c. of mother-of-pearl and olive wood.

Bethlehem, a city of Pennsylvania, on the Lehigh River, 45 miles N. of Philadelphia, is the principal settlement in America of the Moravians, by whom it was founded in 1741. It has silk, paint, and flour mills, and is noted for its excellent schools. Two bridges across the Lehigh connect the former borough of Bethlehem with South Bethlehem, seat of Lehigh University (1866) and other institutions, with iron and steel works. West Bethlehem, across Monocacy Creek, has silk and planing mills, machine-shops, and dye-works. The three boroughs are now united. Pop. 50,000.

Bethlehem, a town of the Orange Free State, 57 miles W. of Harrismith, in an agricultural and coal-mining district; pop. 6000.

Bethlehemites, (1) a monastic order existing in England in the 13th century, who had a monastery at Cambridge, founded in 1257.—(2) A military order established by a bull of Pius II. in 1459, to provide a bulwark against the attacks of the Turks.—(3) A society founded in Guatemala about 1659, and raised to an order by Innocent XI. in 1687.—The followers of John Huss were styled Bethlehemites, from Bethlehem Church in Prague, where their leader preached.

Bethlem. See BEDLAM.

Bethlen-Gabor (i.e. GABRIEL BETHLEN), descended from an ancient and distinguished Protestant family of Hungary, was born in 1580. He rose to prominence during civil troubles in Transylvania, and on the death of Gabriel Bathori succeeded (1613), by the aid of the sultan, in being chosen sovereign prince of Transylvania. In 1619, when the Bohemians rose in defence of their religious and political rights, they looked eagerly for support to Gabor, who was glad of such an opportunity to gratify his ambition at the expense of his enemy, Austria. He accordingly marched into Hungary, took Kaschau, his advance more resembling a triumphal procession

than a hostile invasion, and on arriving under the walls of Presburg, was greeted with acclamations by the citizens. He was subsequently crowned king of Hungary by the assembled diet, August 25, 1620. After various alternations of fortune, in which he was ultimately successful, a peace was in 1621 concluded with Ferdinand II. of Austria, by which Gabor gave up his claims to Hungary and the title of king, but obtained large accessions of territory, and the dignity of prince of the empire. This treaty, however, was soon broken by the emperor; but the prince raised an army of 60,000 men, invaded Moravia, and obtained the solemn renewal of the former treaty. He died in 1629. His reign was a glorious epoch in the history of the principality; for not only did his military successes give a prestige to its arms, but his protection of science and letters did much to aid the progress of learning.

Bethmann-Hollweg, THEOBALD VON (1856-1921), born at Hohenfinow, near Eberswalde, studied law at Stassburg, Leipzig, and Berlin, entered the civil service, and sat in the Reichstag. He became oberpräsident of Brandenburg (1896), Prussian minister of the Interior (1905), and Imperial Chancellor (1909). The Great War placed him in an invidious situation which he lacked strength to cope with. He was dismissed in 1917. See his *Betrachtungen zum Weltkriege* (1919).

Bethnal Green, a north-eastern metropolitan borough, once largely peopled by Huguenot silk-weavers, now a centre of the boot and shoe manufacture, and of tailoring. Its museum is a branch of the Victoria and Albert. Pop. 117,000.

Bethsaida, a village on the western shore of the Lake of Galilee, the birthplace of Peter and Andrew and Philip.—At the north-eastern extremity of the lake was another Bethsaida, scene of the feeding of the five thousand. Philip the Tetrarch renamed it Julias.

Bethulia, scene of the exploits of Judith (q.v.), seems to have been in the north of Galilee, but otherwise unknown has been variously identified with Safed and other places.—**BETHULIE**, named from it, is a town in the Orange Free State, 3 miles from the Orange River; pop. 2500.

Béthune, a town in the French department of Pas-de-Calais, 16 miles NNW. of Arras, with a trade in soap and beet-sugar, suffered heavily in 1918; pop. 17,000. The town was Flemish till 1713. Sully (q.v.) belonged to the family founded there in 970. The Scottish family of Bethune or Beaton (q.v.) is said to have come thence to England with William the Conqueror.

Bet'ony. See STACHYS.

Betterment, an improvement to real property made by a tenant such as justifies him in claiming compensation from the landlord. A betterment tax is one assessed on property benefited by a public improvement.

Betterton, THOMAS, actor, was born in London about 1635, and, after serving as a bookseller's apprentice, turned actor some three years before the Restoration, and in 1661 joined Davenant's theatrical company. The best contemporary judges,

such as Addison, Cibber, Dryden, &c., bear admiring witness to his dramatic powers, which overcame the natural disadvantages of a low voice, small eyes, and an ungainly figure. Pepys thought him the best actor in the world. His private character was highly estimable, cheerful, modest, and generous. In an unfortunate speculation in 1692 Betterton lost all his savings. A public benefit was got up for him on the 6th April 1709, and he acted several times again before his death on 28th April 1710. He was buried in Westminster Abbey. Mrs Betterton, whom he had married in 1662, took the same rank among contemporary actresses as her husband did among actors. Betterton's own eight dramas were adaptations. See Doran, *Their Majesties' Servants* (2d ed. by R. W. Lowe, 1887); and the Life by R. W. Lowe (1891).

Bettia, a municipal town in the north-west corner of Bihar, India, on the line of the Tihut state railway, is headquarters of the Bettiah Raj. Pop. 26,000, about two-thirds Hindus. There has been a Roman Catholic mission here since 1746.

Betting is a mode of gratifying the passion for gambling. It takes a great variety of forms, and, in one form or another, has been pursued in all ages and among all peoples. So powerful are its fascinations for many persons that the exhortations of moral and religious teachers, and the discouragements and the restraints of law, have proved ineffectual to suppress, or even seriously to curb, the practice. Betting or wagering may take place in connection with any uncertain event; and persons addicted to betting are ready to make a bet upon anything. But the practice has come to be specially associated with horse-races and other branches of sport. The habit of betting upon sporting events is, it would seem, now more widespread than in any previous generation. Race-courses and race-meetings have multiplied; sporting intelligence, containing selections of probable winners, betting quotations, and miscellaneous racing chatter, is widely published in newspapers and by other agencies; and the Turf has its adherents in all classes of society. The great development of other branches of sport in recent years has also been accompanied by a corresponding increase of betting in connection therewith.

A betting or wagering contract is one in which the parties mutually agree that, dependent upon the determination of an uncertain event, one shall win from the other, and that other shall pay or hand over to him a sum of money or other stake. There must be something at hazard between the parties, which each of them may either win or lose. Further, it is essential that the real motive of the parties in entering into the contract should be the winning or losing of the stake. If a party has a genuine commercial interest in the issue of the event, antecedent to the contract and independent of the transfer of the stake, this interest furnishes a motive and consideration for the making of the contract other than the winning or losing of the stake, and accordingly the contract is regarded in law as being outwith the category of betting contracts. Thus the distinction between a contract of insurance and a wagering contract lies not in the nature of the contracts, but solely in the presence of what is called an 'insurable interest,' and in the absence of such an interest a policy of insurance is, in law, nothing but a wager. Similarly in many other forms of speculative agreements, in which the gain or loss to either party is dependent on an uncertain event, the presence or absence of antecedent and independent interest in the event on the part of one or both of the parties is taken in law as a working test in determining whether the

agreement was directed to serve a proper commercial purpose or was merely a gambling transaction.

'Gaming' contracts, in which the parties play a game for stakes hazarded by the players, or bet upon the sides or hands of those who play a game, constitute a special class of betting contracts, and are treated in a separate article (see GAMING). Here we are primarily concerned with betting or wagering in the wide sense of the term described in the previous paragraph.

At English common law bets were lawful, and could be enforced by action like any other contract, except when they were calculated to disturb the peace or were contrary to public policy. A bet, for example, upon the conviction or acquittal of a prisoner was held to be unenforceable, as tending to disturb the course of justice. The distinction which English law now makes between betting contracts and other contracts is entirely the creation of statutes, and is based on reasons of public policy. The earlier gaming statutes were concerned exclusively with playing games for stakes or betting on the players (see GAMING). It was not till 1845 that the legislature struck at betting contracts in general, whether relating to games or to other events. The act of 1845 (8 and 9 Vict. chap. 109), which continues to be the governing statute, and extends to bets and wagers of every kind, enacts (sect. 18) that 'all contracts or agreements, whether by parole or in writing, by way of gaming or wagering, shall be null and void; and no suit shall be brought or maintained in any court of law or equity for recovering any sum of money or valuable thing alleged to be won upon any wager, or which shall have been deposited in the hands of any person to abide the event on which any wager shall have been made.' The act, while it makes bets void, does not render them illegal. A person may lawfully make a bet; but the courts do not enforce the contract. It is in the option of the loser whether or not he pay; if he pay after the event, the money cannot be recovered. The act of 1845 did not affect the validity of transactions collateral to, or of implied contracts arising out of, wagers. Thus, if a person employed a commission agent to make bets for him, the agent, if he paid the losses, could sue his employer for the money so paid; and, conversely, if he received payment of winnings, he could be sued by his employer for the amount of these winnings. This state of the law, which was deemed to encourage unduly the employment of commission agents or 'turf-accountants,' was altered by the Gaming Act of 1892 (55 Vict. chap. 8), which renders null and unenforceable any promise, express or implied, to pay any person any sum of money paid by him in respect of any contract rendered void by the Gaming Act, 1845, or to pay any sum of money by way of commission fee or reward in respect of any such contract, or of any services in relation thereto or in connection therewith. Under this act, it will be observed, the position of a commission agent is peculiarly unfavourable; for, while he cannot sue for any fee or commission or for any sum paid by him on his employer's behalf in respect of bets lost, he remains accountable to his employer for all sums received by him on his employer's behalf in respect of bets won.

Money knowingly lent for the purpose of betting on games, or lent at the time and place of play to a player, cannot, in virtue of certain statutes, be recovered (see GAMING); but there is no enactment striking at the recovery of money which has been lent either for the purpose of betting on events other than games or for the purpose of enabling the borrower to pay bets which he had previously lost, whether, in the latter case, the bets were on games or on other contingencies (*Ex parte Lancaster* [1911], 2 K.B. 981).

All bills, notes, cheques, and other securities given in payment of money lost on bets of any kind are unenforceable between the original parties. Under section 2 of the Gaming Act, 1835, money paid to the indorsee, holder, or assignee of securities given for consideration arising out of certain gaming transactions was recoverable from the person to whom the securities were originally given. In *Sutters v. Briggs*, 1922 A.C. 1, it was held that, in virtue of this enactment, the loser of a bet on a horse-race, who had drawn a cheque for the amount of the bet in favour of the winner, was entitled to recover from the winner the amount of the cheque, which had been indorsed by the winner and handed by him to his bankers for collection and had been duly cleared and paid. Following on this decision the Gaming Act, 1922, which came into operation on 20th July 1922, was passed, repealing section 2 of the Gaming Act, 1835, and expressly providing that no action for the recovery of money under that section shall be entertained in any court.

Where money or other valuable thing is deposited with a stake-holder to abide the result of a bet, the winner of the bet is prevented by the terms of section 18 of the act of 1845 (quoted *supra*) from bringing an action against the stake-holder for its recovery. The party, however, who has made any such deposit with a stake-holder has a right to demand back and recover from the stake-holder what he has deposited, even after the event upon which the bet was made has been determined, at any time before the deposit has been actually paid or handed over by the stake-holder to the winner.

In Scotland it is part of the common law that all betting transactions are *sponsiones ludicrae*—matters not serious enough to engage the attention of the courts. The practical effect of this principle is that no action lies on a betting contract either to compel payment of winnings, or to compel repayment of losses which have been paid. Though the Scots courts will not decide a dispute as to who is the winner of a bet, nevertheless, if the winner is not in dispute and a stake has been deposited with a stake-holder, Scots law, differing in this respect from English law, will compel the stake-holder to pay or deliver the stake to the winner. The acts of 1845 and 1892, which govern the law concerning bets in England and Ireland, do not apply to Scotland; for it was thought that the common law of Scotland sufficed to effect the purposes of these acts. The exclusion of Scotland from these acts, however, has had the effect of rendering the law of Scotland in regard to the position of betting agents different from that of the rest of the United Kingdom. Thus in Scotland an action lies at the instance of a betting agent against his employer for the recovery of money disbursed by the agent for behoof of his employer on account of bets lost.

The law as to betting contracts has important applications in the case of 'time bargains' on the Stock Exchange. Where shares are ostensibly bought and sold, but the real intention of both the parties to the contract is merely to pay or receive the differences between the prices on one day and the prices on another day, the sale is merely a device under cover of which the parties gamble on the rise and fall of prices. Accordingly the law, looking at the real and not merely ostensible intention of the parties, treats the transaction as nothing but a bet on the price of the stock at a future day, and the 'differences' cannot be recovered. If the real agreement between the parties was that the stock would not be taken up, but that the account would be settled by payment of differences, the contract is none the less void as being a mere wager, though it bears on its face that one of the parties can demand delivery of the stock.

Betting is not a crime or even an illegal act; but it is a punishable offence to keep a betting-house or to bet in certain ways and in certain places. The particular forms of betting and the particular acts connected therewith struck at by the criminal law are dealt with *s.v.* GAMING. For authorities, see GAMING.

Bettws-y-Coed, a village of Carnarvonshire, where the Conway receives the Llugwy, 15 miles S. of Llandudno Junction by rail. The rich greenery of the vegetation, the waterfalls and streams, the luxuriantly wooded hills all round, with the background of the mighty Snowdon and her sister-peaks, combine to make Bettws-y-Coed almost unique in the variety of its natural beauty. At the 'Royal Oak' is a former signboard, painted by David Cox, who stayed here every year from 1844 to 1856. Pop. (urban district) 1000.

Betty, WILLIAM HENRY WEST, better known as the Young Roscius, born at Shrewsbury in 1791, first appeared on the stage at the age of eleven in Belfast, and achieved an immediate success. For almost five years he sustained the heaviest parts before crowded and enthusiastic audiences, and earned from 50 to 75 guineas nightly. In 1805 Mr Pitt adjourned the House of Commons to permit members to witness the boy's Hamlet. He quitted the stage as a boy-actor in 1808, but after studying for a while at Cambridge, returned to it in 1812. He retired finally in 1824, and lived for fifty years in the enjoyment of the fortune he had so early amassed. He died in London, 24th August 1874.

Betul, a declining town of the Central Provinces, India, 50 miles N.E. of Ellichpur; pop. 5000. Betul district, whose headquarters is Badnur, 3 miles off, is a highland region, rich in forests, and producing coal. Area, 3826 sq. m.; pop. 390,000.

Betula. See BIRCH.

Betwa, a river of Central India and the United Provinces, which, after a north-east course of 360 miles, joins the Jumna.

Beust, FRIEDRICH FERDINAND, COUNT VON, German statesman, one of the most prominent modern politicians, was born at Dresden, January 13, 1809. Having conceived early a liking for politics, he devoted himself to diplomacy, and was employed by his government in various capacities in Berlin, Paris, and London. As minister for foreign affairs for Saxony, he, in 1849, declared against the adoption of the new German constitution, but in 1863 he supported the rights of the smaller German states on the Sleswick-Holstein question. In 1866, however, his friendship for Austria induced him to join that country in the war with Prussia, against the wishes of at least the liberal party in Saxony. He afterwards entered the service of Austria, and rose in 1867 to the head of affairs. The chief result of his policy in the reorganisation of the empire was the reconciliation of Hungary, although he afterwards disclaimed the honour of introducing dualism into the empire, and declared that he did so because only Déak's plan would satisfy Hungary. A zealous Protestant, he was an opponent of the Ultramontanes, and his tenure of office saw the removal of Jewish disabilities, and the establishment of civil marriages. Having failed in 1870 to keep his engagements to France, he resigned the office of chancellor in 1871, and though he was afterwards ambassador at London (1871-78) and Paris (1878-82), he never again took a prominent part in politics. He died October 24, 1886. See his *Memoirs* (Eng. trans., with an introduction by Baron Henry de Worms, 2 vols. 1887).

Beuthen, a town of Prussian Silesia, 121 miles S.E. of Breslau by rail, close to the Polish frontier. It lies in a mining district (mainly Polish, 1921),

and manufactures woollen cloths and earthenware. Pop. (1871) 17,942; (1900) 51,409; (1919) 71,187.

Beveland, NORTH and SOUTH, two Dutch islands in the estuary of the Scheldt. South Beveland is the largest and most fertile of the Zeeland (q.v.) islands. North Beveland is low and marshy.

Beveridge-gear. See GEARING.

Beveren, a town of Belgium, in East Flanders. The principal industry is the making of point-lace. There is a noticeable church. Pop. 11,000.

Beveridge, WILLIAM, Bishop of St Asaph, was born at Barrow, Leicestershire, in 1637, and entering St John's College, Cambridge, in 1653, as a sizar, devoted himself to the study of the classical and Semitic languages, on which latter he published a treatise at the age of twenty. In 1661, having obtained his degree of M.A., he was ordained both deacon and priest. After holding various preferments, in which he was remarkable for his devotion to his pastoral duties, he was, in 1704, appointed to the bishopric of St Asaph, having previously refused to accept that of Bath and Wells, on the deprivation of Dr Thomas Ken for not taking the oaths to the government of William III. He died 5th March 1708. His sermons and other works were published in 1824 (9 vols.); and there is another edition in the Library of Anglo-Catholic Theology (12 vols. 1842-46); but *Private Thoughts upon Religion* (1709) is his only work now read.

Beverland, ADRIAN, a Dutch scholar, who, by several of his writings, but more especially by his unorthodox interpretation of the Fall, caused great excitement among the theologians of his day. Born at Middelburg, in Zeeland, about the middle of the 17th century, he had studied law, visited Oxford University, and settled as an attorney in Holland, when, in 1678, he published his pamphlet, *Peccatum Originale*, which not only was burned at the Hague, but led to his own imprisonment, and to his expulsion from Utrecht and Leyden. On his return to the Hague, he wrote *De Stolata Virginitatis Jure* (1680), which gave still greater offence than his first work. Soon after, he came to England, where he found a supporter in Isaac Vossius. He became insane, and died in England soon after 1712. His works are now mere bibliographical curiosities.

Beverley, chief town of the East Riding of Yorkshire, and see of a suffragan bishop under York, is 1 mile W. of the river Hull, and 8 miles NNW. of the city of Hull. It trades in corn and coal, has tan-works, and manufactures agricultural implements. Incorporated as a borough in 1573, it elected two M.P.'s till 1870. Here is the superb Gothic minster, or the Collegiate Church of St John, ranking next to York Minster among the ecclesiastical structures of the county, and exhibiting different styles of Gothic architecture, the oldest part being of the 13th century. It is 334 feet long and 167 across the transept; the western towers are 200 feet high. The choir contains the celebrated Percy shrine, of the most exquisite workmanship. The minster has been restored since 1867 by Sir G. G. Scott, by whom, too, was restored the fine cruciform church of St Mary. The 14th-century North Bar is the sole survivor of four old gates. The grammar-school of Beverley is so old that the date of its foundation is unknown. Beverley arose out of a priory founded by St John of Beverley, who was born at the neighbouring village of Cherry Burton, became Bishop of Hexham first, and then of York, and died in 721. The name is a corruption of *Beveriac*, 'lake of beavers.' Pop. (1851) 10,058; (1881) 11,442; (1921) 13,469.

Beverloo', a village of Belgium, in the province of Limbourg, 12 miles NW. of Hasselt. On the heath near is a permanent military camp. Pop. 1000.

Beverly, a town of Massachusetts, on an arm of the Atlantic, opposite Salem, with which it is connected by a bridge, and 18 miles NE. of Boston by rail. It has a good harbour, with fisheries, and manufactures shoes. Pop. 22,500.

Bevis of Hampton, the hero of a popular English medieval romance. The son of Sir Guy, Earl of Hamtoun, who was treacherously murdered by Divoun, emperor of Almayne, he was given by his false mother to some heathen merchants to be sold for a slave among the Paynim. By them he was carried to Ermony, where he soon became dear to King Ermyn, and dearer still to his only daughter, the lovely Josian. His chief exploits were the overthrow of Brademond of Damascus, of a monstrous boar, of the giant Ascapard whom he spared to become his squire, and of a dreadful dragon near Cologne. His famous sword Morglay he won in battle; his horse Arundel was the gift of Josian. Still more romantic episodes in his story are his carrying his own death-warrant in a sealed letter to the vassal Brademond, his escape from his noisome dungeon after seven years' imprisonment, and recovery of his wife who had preserved his love, though nominally the wife of King Ynor of Mombrant. He next returned to England to avenge his father's death, then sailed for Ermony and defeated Ynor in a desperate battle. His last great fight was in the streets of London, when he slaughtered sixty thousand citizens, and forced King Edgar to grant him terms. Thirty-three years he then spent in love and perfect happiness at Ermony, dying at the same moment as his wife, while his famous steed Arundel had died just before. The romance was edited by Dr E. Kölbing for the Early English Text Society in 1885-94.

Bewcastle, a village of east Cumberland, 10 miles NE. of Brampton. Pop of parish, 600. A headless stone cross in the churchyard, 14½ feet high, bears an English runic inscription, which, according to some, shows the cross to belong to the latter half of the 7th century. Others date it four or five centuries later. See RUNES.

Bewdley (formerly BEAULIET, from its pleasant situation), a municipal borough on the right bank of the Severn, Worcestershire, 14 miles NNW. of Worcester, on the Severn Valley Railway. Till 1885 Bewdley returned one member to parliament. It has manufactures of leather, combs, malt, carpets, and iron and brass wares. Near the town is a public park of 400 acres. Bewdley in the 13th century had a right of sanctuary for those who had shed blood. Henry VII. built a palace at Bewdley for his son Arthur, married here by proxy to Catharine of Aragon. Pop. 2800.

Bewick, THOMAS, to whom the modern revival of the art of wood-engraving is mainly due, was born at Cherryburn, Ovingham, Northumberland, August 12, 1753. His father was a farmer and the lessee of a colliery, and during his early years he enjoyed the ordinary life of a country boy, greatly interested in field-sports, and laying the foundation of that knowledge of the face of nature and of the appearance and habits of her living creatures, which afterwards so strongly influenced his artistic productions. Soon he began to depict the things that he had seen, embellishing the margins of his school-books, and sketching with chalk on floors and on the flat stones of the churchyard. At the age of fourteen he was apprenticed to Ralph Beilby, a Newcastle engraver, who turned out work of the most miscellaneous description, and the first woodcuts that he produced were a

series of diagrams illustrating Dr Hutton's *Mensuration*, published in 1768-70. In 1776, after the expiry of his apprenticeship, Bewick settled as an engraver in London; but the ways of the metropolis were little to his taste, and in less than a year he returned to Newcastle. Soon after, he became the partner of his former master, and taking his brother John Bewick (born 1760, died 1795) as an apprentice, he executed, probably with his assistance, the woodcuts for an edition of *Select Fables*, published in 1784. Towards the close of the following year Bewick began to work upon the blocks of the animals and of the vignettes and tailpieces of his *History of Quadrupeds*, issued in 1790, which fully established his reputation as an engraver. They were mainly drawn and cut in the evenings, after the ordinary routine of the shop was ended; and the accompanying letterpress was compiled by his partner. During the progress of this work he executed in 1789 his 'Chillingham Bull,' a large woodcut, which some have regarded as his masterpiece.

The success of the *Quadrupeds* led to the publication of a similar *History of British Birds*, in which the artist's highest powers were manifested, and which, like his other great works, has appeared in numerous successive editions. The first volume, dealing with land-birds, was issued by the firm in 1797, and the second, on water-birds, in which he was aided by such talented pupils as Johnson and Clennell, was published by Bewick alone in 1804. The figures of the various birds are rendered with the utmost spirit and accuracy, and as examples of powerful and finely decorative arrangements of black and white, nothing could surpass his 'Eagle Owl,' his 'Short-eared Owl,' and his 'Goldfinch.' The tailpieces are vivid renderings of landscape and of rustic life, and are frequently touched with a homely and most vigorous humour. In technical method these illustrations show an immense advance upon all previous examples of wood-engraving. Self-taught, and working from his own designs, Bewick instinctively adopted such methods as were in truest harmony with the especial capabilities of his material, working with white lines into the lights, from the black tint given by the untouched block. Each touch of his graver is laid with intention and definite meaning; and while later engravers have far surpassed him in finesse and manual dexterity, and have produced on wood marvellous imitations of other styles of engraving and surprising transcripts of the tone and texture of brush-work, Bewick's cuts will always maintain their place as classic in their kind, as standard examples of right aims and true direction in wood-engraving. On the *Aesop's Fables* (1818) he was engaged for six years. Latterly he was assisted by William Temple and William Harvey, and by his son, Robert Elliott Bewick (1788-1849). He died 8th November 1828.

See his own autobiography (1862); Hugo's *Bewick Collector* (1866-68); the Life by Thomson (1882); *Bewick and his Pupils*, by Austin Dobson (1884); and books named at WOOD-ENGRAVING.

Bex, a village in the Swiss canton of Vaud, 26 miles SE. of Lausanne, with great salt-mines, salt-works, and sulphur-baths; pop. 5000.

Bexhill-on-Sea, a health-resort on the Sussex coast, 5 miles SW. of Hastings, was made a municipal borough in 1902; pop. 20,000.

Bexley, an urban district in the west of Kent, 15 miles SE. of London, and 3 W. of Dartford; pop. 21,000.

Bey. See BEG.

Beybars, or BIBARS, the Mameluke commander who in 1250 defeated St Louis at Damietta, became

sultan of Egypt in 1260, waired victoriously with Christians and Tatars, took Damascus and Antioch, and died at Damascus in 1277.

Beyerland, one of the island-districts of south Holland, and lying between the Maas and the Hollandsche Diep. It is 15 miles long.

Beyerlein, FRANZ ADAM, German dramatist, novelist, and critic, was born at Meissen, 22d March 1871, and studied at Freiburg-im-Breisgau and Leipzig. Two of his works, the novel *Jena oder Sedan* (1903) and the drama *Zapfenstreich* (1903) were much discussed.

Beyle, MARIE-HENRI, a French author, better known by his *nom de guerre*, 'Stendhal,' born at Grenoble, 1783, was painter, government-clerk, soldier, and merchant by turns, and accompanied the fatal Russian campaign of 1812. After some years' residence in Milan, he returned in 1821 to Paris, where he acquired a high reputation as a *littérateur*. He was consul at Trieste and Civita Vecchia from 1830 to 1841, and died at Paris, March 23, 1842. Stendhal's keen powers of criticism and psychological analysis give greater value to his works on art and music than to his romances, although the same piquant style, brilliant wit, and wide knowledge of the world appear in all his writings. His defects are a morbid straining after originality, and an ostentatious cynicism and contempt for moral sentiment. His best novels, which all lack consistency of plot, are *Le Rouge et le Noir* (1830) and *La Chartreuse de Parme* (1839). His principal critical works are *Histoire de la Peinture en Italie* (1817); *De l'Amour* (1822); *Racine et Shakespeare* (1823), which greatly aided the cause of romanticism; *Vie de Rossini* (1824); and *Promenades dans Rome* (1829). His hero Sorel is autobiographical, and lives only for intrigue; *De l'Amour* has been called the breviary of the seducer and the hypocrite. Stendhal was the father of the analytic novel.

See Sainte Beuve's *Causeries du Lundi*, vol. ix.; Bourget's *Psychologie Contemporaine*; Hewlett's introduction to *La Chartreuse*; the edition of his works by Debraye (35 vols. 1913 et seq.); and books on Beyle by Paton (1874), Rod (1892), Brun (1900), Chuquet (1902), and Arbelet (1920).

Beypur, a seaport in Malabar district, Madras, 6 miles S. of Calicut; pop. 4000.

Beyrich, HEINRICH ERNST VON, German geologist (1815-96), born at Berlin, studied there and at Bonn, became a museum director and professor in Berlin, and joint-director of the Prussian Geological Survey. He introduced the term Oligocene.

Beyrout, or BAIRUT, believed to be the *Berothai* or *Berothah* of the Old Testament (2 Sam. viii. 8 and Ezek. xlvii. 16), and known to the ancients, under the name of *Berytus*, as a Phœnician seaport belonging to Sidon, is a flourishing commercial town, situated in a most picturesque position on the coast of Syria, and at the foot of Lebanon, 55 miles from Damascus, and 147 from Jerusalem. It was for a few years in the hands of the Christians (12th century), and was subject successively to the Saracen, Seljuk, and Turkish sultans. In 1840-41 it was bombarded by the British fleet under Sir C. Napier, taken from the Egyptians, and delivered over to the Turks. The French occupied it 7th October 1918, attached it, somewhat loosely, to Lebanon, and made it the seat of the Syrian government. Beyrout imports Manchester goods, woollens, Rangoon rice, hides, copper, iron, and coal; exports corn and silk; and there is direct trade to the East in various commodities. Till the harbour allowing ships to discharge cargo at the quays was constructed by a French company in 1894-97, sea-going ships could not approach within

half a mile of the shore, and shelter had to be sought during stormy weather in St George's Bay, about 3 miles from the town. Commerce had very largely increased, but received a check from the political changes that followed the Great War, and suffered seriously from the rivalry of Haifa and other ports. Shipbuilding has received some attention. In 1859 a line of omnibuses, the first ever seen in Syria, was established, and a French company completed in 1863 a good road to Damascus, of which Beyrout is the port; in 1875 an English company completed an extensive system of water-works, and in 1890-95 a railway was made from Beyrout to Damascus. There are French Jesuit and Scottish missionary institutions here, as also the *dépôt* of the American-Syrian mission, with a school, printing-press, and medical staff, and a Greek patriarchal college. Pop. about 180,000 (70 per cent. Christians).

Beyschlag, WILIBALD (1823-1900), evangelical theologian, born at Frankfurt, was appointed professor of Theology at Halle in 1860. His *Leben Jesu* (3d. ed. 1893) and *Neutestamentliche Theologie* (trans. 1895) are standard works; others are *Die Christologie des Neuen Testaments* (1866); *Die Paulinische Theodicee*, Rom. 9-11 (1868); *Die Christliche Gemeindeverfassung im Zeitalter des Neuen Testaments* (1874); *Zur Johanneseischen Frage* (1876); and *Christenlehre auf Grund des kleinen Lutherschen Katechismus* (1900). In 1876 he founded the *Deutsch-evangelische Blätter*.

Beza, THEODORE (properly De Bèze), next to Calvin the most active and influential of the Genevese reformers, was born of a noble family at Vezelay, in Burgundy, 24th June 1519. He received an admirable education at Orleans and at Bourges in the house of Melchior Volmar, a learned German, who taught him Greek, and also imbued him with the principles of the Reformation. As early as 1539, Beza became known as a writer of witty and elegant but indecent verses, the publication of which (1548) caused him many bitter regrets in after-days. After studying law at Orleans, he obtained his degree as licentiate of civil law in his twentieth year, and went to live in Paris, where he appears to have spent several years in fashionable dissipation. His handsome figure, together with his fine talents and good birth, opened to him the most brilliant prospects. It was the desire of his relatives that he should enter the church, but a private marriage which he had contracted rendered this impossible.

After a severe illness, during which the sinfulness of his career presented itself to his conscience, he went to Geneva along with his wife, October 1548. Shortly after, he was appointed Greek professor at Lausanne, an office which he held for ten years. In 1550 he published with success a drama, entitled *The Sacrifice of Abraham*, and delivered lectures to crowded audiences on the Epistle to the Romans and the Epistles of Peter. Out of these lectures ultimately grew his translation of the New Testament into Latin. In 1559 he went to Geneva, where he became Calvin's ablest coadjutor, and was appointed a theological professor and president of the college. He had already signalled himself by his work *De Hæreticis a Civilis Magistratu Puniriendis* (1554), in which, like many other honest but mistaken men, he approved of the burning of Servetus.

Beza was as skilful a diplomatist as a theologian. He induced the king of Navarre to exert his influence on behalf of the persecuted French Protestants, and was persuaded by the latter to attend the conference of Catholic and Protestant divines held at Poissy in 1561. Here his courage and dexterity made a very favourable impression on the French court. While in Paris he often preached before the king of Navarre and Condé. On the out-

break of the civil war he accompanied the latter as a kind of military chaplain, and after his capture attached himself to Coligny. In 1563 he once more returned to Geneva. The following year Calvin died, and the care of the Genevese church now fell principally upon Beza's shoulders. He presided over the synods of French reformers held at Rochelle in 1571 and at Nîmes in 1572. In 1574 he was deputed by Condé to transact important business at the court of the Palatinate; and in 1586 measured himself with the Wurtemberg divines. After the death of his first wife in 1588, though verging on seventy, he married again. In 1597 his calumniators spread the extremely foolish report that he was dead and at the last hour had returned to the bosom of the church. The witty patriarch replied in a poem full of sparkling vigour. He died 13th October 1605. He is best known for his translation of the New Testament into Latin, and the *Histoire Ecclésiastique des Églises Réformées de France, 1521-1563* (3 vols. 1580), partly his, but mostly by Jean des Gallands. There are lives by Schlosser (1809), Baum (1851), Heppe (1861), Baird (1900), Picard (1906).

Bezants, or BYZANTINES, are coins of the Byzantine empire. The gold bezant varied in value at different times from a sovereign to half a sovereign; the silver one from a florin to a shilling; are of gold and silver; bear impressions distinct from those of the earlier Roman coins; and were copied in several countries where the Byzantine standard was adopted. The commercial relations of the Eastern empire served to distribute its coinage over almost all the then known world. It was current in India as well as in England till the reign of Edward III. (see NUMISMATICS). Bezants were brought home by the Crusaders, and hence are of frequent occurrence as heraldic charges. Similar figures, when not coloured *or* (gold), or *argent* (silver), are known in heraldry by the general term of *roundels*. A *bezanty cross* is a cross composed of bezants.

Bezdan, a town of Yugoslavia (Hungary till 1920), in the Bachelka, on the canal joining the Theiss and the Danube, from which latter river it is about 3 miles distant. Much hemp is grown. Pop. 8000.

Béziers, a town in the French department of Hérault, is pleasantly situated on a hill in the midst of a fertile country, at the junction of the Orb and the Canal du Midi, 49 miles SW. of Montpellier by rail. It contains some interesting architectural buildings, the principal being the cathedral, a noble Gothic edifice, and the ancient episcopal palace; and antiquarian remains dating from before the time of the Romans. Beziers has manufactures of silk stockings, woollens, gloves, parchment, glass, soap, leather, brandy, and much esteemed confectionery. Population, about 56,000. In 1209 the inhabitants were indiscriminately put to the sword by Simon de Montfort and the pope's legate for having afforded protection to the Albigensian fugitives.

Béziq (also called *Besique*), a game at cards, played with a double pack, in which the objects are principally to promote in the hand certain combinations which, when 'declared,' entitle the holder to score, and to win certain cards of a particular value. There are practically no restrictions in the game; it is not necessary to follow suit; and two, three, or four players may engage in it.

Be'zoar (through Fr. and Span. from Persian *pād-zahr*, 'counter-poison,' *zahr*, 'poison'), a concretion found in the stomachs of goats or antelopes, and formerly much valued on account of imaginary medicinal virtues, particularly as an antidote to

poisons. Concretions of various kinds are found in the stomachs of herbivorous quadrupeds, very generally having for their nucleus some small indigestible substance which has been taken into the stomach. Sometimes they are of a radiating structure; sometimes formed of concentric layers; sometimes they are principally composed of superphosphate of lime; sometimes of phosphate of ammonia or magnesia. Other concretions found in the intestines, &c. of various animals are sometimes also called bezoar (see CALCULUS). The value of a bezoar being supposed to increase with its size, the larger ones have been sold, particularly in India, for very great prices.

Bhagalpur, or BOGLIPOOR, a town of Bihar, stands on the right bank of the Ganges, here 7½ miles wide, and by rail is 265 miles NW. of Calcutta; population, 70,000.—The long, narrow district of Bhagalpur, lying S. of Nepal, has an area of 4226 sq. m., and is divided into two nearly equal portions by the Ganges. The lowlands are fertile and well cultivated. Indigo is the chief manufacture, and rice and other cereals are the principal articles of export. Of the population (over two millions) 90 per cent. are Hindus.—The division of Bhagalpur comprises five districts.

Bhagavad Gītā ('The Song of the Adorable') is the title of a lengthy theosophical poem which has been incorporated in the great Indian epic, the Mahābhārata, although it is clearly of later date than the rest of that work, its composition being usually assigned to the first or second century after Christ. The leading theme of the poem is the exaltation of the god Vishnu in his human form or avatār of Krishna, and throughout it the god speaks in his own person. In this incarnation Vishnu became the charioteer of Arjuna, a chief of the Pāndus, who were then at war with their kinsmen, the Kurus. On the eve of a battle, when Arjuna is appalled at the thought of slaughtering his own kindred, Krishna sets before him the duties demanded of him as a member of the warrior caste, and at the same time propounds an eclectic system of philosophy of an ethical pantheistic type, laying especial emphasis on the doctrine of *bhakti*, or faith in the Supreme Being, whom he declares himself to be. The poem is divided into three sections, each containing six chapters, called *upanishads* ('secret doctrine'), a name which shows the mystical character of the work. In the first section, the duties and observances of caste are directly inculcated, and asserted to be entirely in harmony with the principles of the Yoga philosophy—viz. asceticism and meditation, by which absorption in the Deity, the highest object of humanity, is attained. In the second, the pantheistic doctrines of the Vedānta philosophy are expounded and taught. In the third, the pantheism of the Vedānta is interwoven with the dualism of the Sāṅkhya philosophy. The remarkable singularity existing between many of the ideas and expressions of the poem and those of the New Testament led some scholars (needlessly) to infer an actual borrowing from the latter, a theory vigorously combated by Telang. It is now generally referred to the centuries preceding the Christian era.

The Bhagavad Gītā was edited by Schlegel (Bonn, 1846), with a Latin translation, and by Thompson (1855). It was translated into English by Wilkins (1785), Thompson (1855), Davies (1882), Telang (1875), and in 'Sacred Books of the East,' vol. viii., Chatterji (1887), Sir Edwin Arnold (*The Song Celestial*, in verse, 1885), M. N. Dutt (1895), and Barnett (1905); also into German, French, Italian, and modern Greek, as well as into most of the modern Indian languages. See MAHĀBHĀRATA and SANSKRIT LITERATURE.

Bhagelkhand. See BAGHELKHAND.

Bhagirathi, a branch of the Ganges, regarded as sacred by the Hindus, leaves the Ganges in the Murshidabad district, forms the boundary-line between Nadiya and Bardwan districts, and joins the Jalangi at Nadiya town to form the Hugli. In Nadiya district, on the left bank of the river, is the field of Plassey.—Also the name of a head-stream of the Ganges, rising in Gangotri Peak, Gairwal, United Provinces, which joins the Alaknanda at Deoprayag.

Bhagul. See BAGHAL.

Bhamo, a town of Burma, is at the head of the navigation of the Upper Irawadi, near the Chinese frontier, and 300 miles from Mandalay. It is the northern terminus of the Irrawaddy Flotilla Company. It has long been a mart of Burmese trade with China; and attention has been directed to it, especially since the annexation of Upper Burma by Britain, as an important centre for the development of trade between India and China through western Yunnan, along the trade routes to the eastward. Its trade was rudely disturbed by the Panthay rebellion. It recovered slightly on the re-establishment of the Chinese imperial power in 1874, but has never been fully restored. The railway touches the Irawadi at Katha, 50 miles below Bhamo in a straight line, and at Myikyina, 70 miles above. Pop. 10,000, Burmans, Shans, and Chinese.—The district has an area of 4146 sq. m. It is largely alluvial, and the vegetation is rich.

Bhandara, capital of a district in the Central Provinces, 40 miles E. of Nagpur; pop. 7500.

Bhang, the native name for the Indian variety of Hemp (q.v.) and Hashish (q.v.).

Bhanpura, a walled town of central India, in Indore state, on the Rewa, 60 miles S. of Kotah; pop. 6000.

Bharatpur, or BHURTPORE, the capital of a protected state in Rajputana, is a large town, measuring about 8 miles in circuit, 35 miles W. of Agra by rail. It is worthy of notice chiefly on account of its two sieges in 1805 and 1827. The strength of the place lay in a mud wall, which was practically shot-proof, and a surrounding ditch, which baffled four successive assaults by Lord Lake. On the second occasion, however, Lord Combermere carried the fortress by mining. Pop. (1891) 68,033; (1911) 33,918.—The state has an area of 2000 sq. m.; pop. 500,000, mostly Jāts. It suffers from want of water, having only one river flowing through it; and yet in many parts the soil is rendered highly productive by means of irrigation. The military force of the state amounts to 10,000 men of all arms.

Bhartrihari is the name of a celebrated Indian writer of apothegms, of whom but little is known. A legendary story makes him the brother of King Vikramāditya, who lived about the middle of the 1st century B.C., and relates of him, that after a wild licentious youth, he betook himself in later years to the ascetic life of a hermit. His name has been given to a collection of 300 apothegms, arranged in three centuries or groups of a hundred (*catāka*), but it is likely that these were the work of various authors, but ascribed, according to the Indian custom, to a well-known name. Cheerful descriptions from nature, and charming pictures of love, alternate in these apothegms, with wise remarks upon the relations of life, and profound thoughts upon the Deity and the immortality of the soul. Böhlen published an excellent critical edition (2 vols. Berlin, 1833-50), as well as a successful metrical translation into German (Hamburg,

1835). Bhatrihari has a special interest as the first Indian author known in Europe, 200 of his apothegms having been translated by the missionary, Abraham Roger, in 1653. See editions and translations by Purohit Gopi Nath (1896), Kale and Gujjar (1898), and the translation by Wortham (1886).

Bhatgaon, a town of Nepal, 8 miles SE. of Khatmandu, conquered by the Gurkhas in 1768-69; estimated pop 30,000.

Bhaunagar (*Bhavanagar*), capital of an Indian state within the boundary of Bombay, on the Gulf of Cambay. 60 miles NW. of Surat; pop. 60,000.

Bhavabhūti, surnamed 'Śrī-kantha,' a great Indian dramatist, who flourished in the first half of the 8th century, and wrote three plays and a domestic drama (see *SANSKRIT*). Bhavabhūti is often compared with Kālidāsa, whom he equalled in vigour and variety, but hardly in genius. All three plays have been translated into English.

Bhel, or *BAEL*. See *ÆGLE*.

Bhils, a pre-Aryan race of central India, inhabiting the states from the Khandesh district of Bombay to the wild hilly tracts of the Vindhya range, north of the Nerbudda River. In 1825 James Outram organised a Bhil corps in order to utilise the war-like instincts of the people, and at the same time the first Bhil agency was formed. The Bhils are dark, diminutive men, perhaps the pygmies of Ctesias (400 B.C.), brave and active, but predatory and superstitious. In normal habit of life they have been nomadic, wandering about with their sheep and goats, and living chiefly on game and fruit. Of over 1,600,000 a few have settled to agriculture, industries, and Hinduism, but the bulk are savages.

Bhilsa, a town of India, in Gwalior state, 26 miles NE. of Bhopal. At Sanchi, near Bhilsa, is a famous group of topes (see *TOPE*). Pop. 8500.

Bhiwani, a town of the Punjab, 37 miles SE. of Hissar by rail. It is the chief commercial centre of the district, and a brisk trade is done in sugar, salt, spices, and metals. Pop. 31,100.

Bhopal, a native state in central India, whose capital, Bhopal (pop. 55,000), is 325 miles SW. of Allahabad. The state has an area of 6900 sq. m., and has long been one of the best-governed native states in India. Founded by Dost Mohammed in 1723, it became dependent on Britain in 1818, and since 1842 the throne has descended through females (the only state in India so ruled), daughter succeeding mother as Begam. A constitution was granted in 1922. The state is Mohammedan, though the mass of the people are Hindus. The state suffered heavily from famine in 1896-1900. Pop. 700,000. See two books (in English) by the accomplished and energetic Begam—an account of her pilgrimage to Mecca, and her autobiography (1912).

Bhuj, the capital of the Indian native state of Cutch, 180 miles SE. of Hyderabad. Its mosques and pagodas, interspersed with plantations of dates, give to the town an imposing appearance from a distance. Pop. 21,600.

Bhurtpore. See *BHARATPUR*.

Bhutan, an independent state in the eastern Himalayas, bounded on the N. by Tibet, S. and E. by Assam, and on the W. by Sikkim. It is divided into East and West Bhutan. With summits exceeding 24,000 feet, the whole surface may be described as mountainous, abounding in sublime and romantic scenery, with a gradual slope from north to south. Generally speaking,

the middle ranges are the most productive. While the south presents but a scanty vegetation, and the north rises far above the limit of perpetual snow, the central regions, at an elevation of 8000 or 10,000 feet above the sea, are covered with the finest forests of oak and pine, with beech, ash, birch, and maple. Amongst wild animals, elephants are numerous, and leopards, deer, wild hogs, bears, and the rhinoceros are also found. The Manās, a tributary of the Brahmaputra, is the most considerable river. Turnips grow well, and nearly all sorts of grain—wheat, barley, rice, maize, and buckwheat—are here and there cultivated on terraces cut out of the sides of the hills. The foreign trade, which consisted in the exchange of commodities for native cloths, rock-salt, rhubarb, Tibet goods, mules, and the famous Tangistan horses or ponies, has declined. The nominal religion is Buddhism, but amongst the common people this goes little further than the recital of a few sacred sentences and the propitiation of evil spirits. From the 16th century till 1907 there was a dual government—the Dharma Raja on the spiritual side and the Deb Raja on the laic. In 1907 the Dharma Raja, who was also the Deb Raja, resigned, and Sir Ugyen Wangchuk, G.C.I.E. (1861-1926), was elected first hereditary Maharaja of Bhutan. Foreign relations are now under British control. Polygyny and polyandry are common. The lower orders are dirty in their persons and habits; their food is mostly pork, turnips, rice, barley-meal, and brick-tea. They are neatjoiners, and their houses of three and four stories have the appearance of Swiss chalets, but are without chimneys. The winter capital is Punakha, on the Bugui River, 96 miles NE. of Darjeeling. The summer capital is Tasichozong (Tassisudon), on the Gudada River, a centre of Lamaism. The original inhabitants, believed to be from Kuch Behar, were called Tephu; they were subdued by a band of Tibetan soldiers 200 years ago, who settled in Bhutan. The Bhutias speak a dialect of Tibetan. In 1772 the raja of Kuch Behar received assistance from the British government against their invasions. Later raids led to the treaty of 1865, when the eighteen Dvars or passes of Bengal and Assam were ceded to the British government in return for a yearly subvention. The area is estimated at 20,000 square miles. Population, 250,000.

See works by Pemberton (1837), Ashley Eden (1864), Strahan (1889), and Sandberg (1898); and *Sikkim and Bhutan*, by Sir J. C. White, political officer in Bhutan (1909).

Biafra, BIGHT OF, at the head of the Gulf of Guinea, between Capes Formosa and Lopez, into which flow the Niger (q.v.), the New and Old Calabar rivers, the Rio del Rey, the Cameroons, and the Gabun; its islands are Fernando Po (Spanish), and St Thomas and Prince's Islands (Portuguese). Opposite Fernando Po are the Cameroons (q.v.).

Białystok (a Polish name the Russians spell *Bielostok*), a town in Poland, on the Biala, 45 miles SW. of Grodno. Its castle, now used as a convent, was formerly the 'Versailles of Poland.' Its factories produce woollens, silks, boots, and shoes. A massacre of Jews took place here in June 1906. Pop. 77,000. It gives name to a voyvodship; pop. 1,300,000.

Biana. See *BAYANA*.

Biancavilla, a town of Sicily, on the south-west declivity of Mount Etna, 24 miles NW. of Catania. It has a trade in grain, cotton, and silk. Pop. 15,000.

Blanchini, FRANCESCO, antiquary and astronomer, was born in 1662 at Verona. At Padua he

studied theology, mathematics, and botany; and in 1684 proceeded to Rome, where he became intimate with the most distinguished *savants* of the day, and devoted himself to the study of jurisprudence and foreign languages. Alexander VIII. bestowed upon him a rich benefice, and Clement XI. appointed him secretary to the commission for reforming the calendar. He died in Rome in 1729. He was author of various works, but is chiefly remembered in connection with the Meridian Line (q.v.).

Bian'coni, CHARLES, born in Lombardy in 1786, came at the beginning of the century to Ireland as an itinerant vendor of cheap prints. Having accumulated a small capital, he started the first public conveyance between Clonmel and Cahir in 1815, at a time when the peace and the carriage-tax had filled the market with cheap horses and jaunting-cars. The enterprise succeeded, until, 40 years after, Bianconi's cars were working over 4000 miles of road daily. Having realised a large fortune, he retired in 1865, and died in September 1875, at his estate near Cashel. He was a devoted adherent of O'Connell, into whose family both his son and daughter married.

Biard, AUGUSTE FRANÇOIS, a *genre* painter, born at Lyons in 1798, travelled in early life in the Levant, in 1839 visited Greenland and Spitsbergen, in 1858-59 Brazil, and in 1865 travelled round the world. Among his best pictures are the 'Beggars Family,' 'African Slave-market,' 'Fight with Polar Bears,' and 'The Wandering Comedians.' He died in Paris, June 1882. His wife, Léonie d'Aunet (1820-79), separated from him since 1845, was author of some novels, a play, &c.

Biarritz, a favourite watering-place in the French department of Basses-Pyrénées, on the Bay of Biscay, 6 miles SW. of Bayonne. Here, in 1855, Louis Napoleon built the Villa Eugénie for the empress, who already, as Countess de Téba, had been a frequent visitor. Till 1855 a decayed fishing-village, Biarritz is to-day a bright, flourishing little town with 19,000 permanent residents, a fashionable international seaside resort, whose mild climate, proximity to the Pyrenees, Basque country, and Spain, picturesque cliffs, and extensive bathing-beaches (Grande Plage and Côte des Basques), fine hotels and villas, casino, thermal establishment, golf-course, &c., attract thousands of visitors all the year round. Since Queen Victoria's visit in 1839 it has been much frequented by English people, especially in winter.

Bias, one of the Seven Wise Men of Greece, a native of Priène in Ionia, flourished about the middle of the 6th century B.C., famous for his eloquence, his nobility of character, and his apothegms. Among these perhaps the best were: 'Know and then act,' 'He is unfortunate who cannot bear misfortune,' 'So order your affairs as if your life were to be both long and short,' and that addressed to the irreligious sailors who during a storm were loudly calling on the gods, 'Be quiet, lest the gods discover that you are here.' Once when his fellow-townsmen in alarm before an enemy were hastily carrying off their valuables, Bias was seen without a burden, and being asked why he was not occupied like others, replied in words which in Latin became a proverb, *Omnia mea mecum porto* ('I carry all my goods with me').

Bias. See BOWLS.

Bib, also called BRASSY, POUT, or WHITING POUT (*Gadus luscus*), a fish of the same genus as the Cod, Haddock (q.v.), and Whiting, pretty common on many parts of the British coasts, found also on those of Norway, Sweden, Greenland, &c. It is

seldom more than a foot long, but differs from the other British *Gadidae* in the great depth of its body, which equals at least one-fourth of the entire length. The back is arched, and the nape exhibits a rather sharp ridge. The head is invested with a loose dilatable membrane. The names Bib and Pout, both originally local English names, were at one time supposed to refer to distinct species (*G. lusca* and *G. barbata*), but these, probably, are really one.

Biberach, a town of Württemberg, delightfully situated on the Reiss, 23 miles SSW. of Ulm. It retains its old ramparts and towers, and in front of the theatre is a monument to Wieland, who was born in the neighbourhood. There are manufactures of machinery, artificial flowers, leather, bells, children's toys, &c. Pop. 9000. In 1796 Moreau won a great victory over the Austrian general Latour at Biberach, the latter losing 4000 prisoners. Here also, in 1800, Saint Cyr defeated the Austrian general Cray. Biberach fell into the possession of Baden in 1802, but four years afterwards was ceded to Württemberg.

Bible. The Bible is the sacred book of the Christian religion. What the Koran is to the Mohammedan world, or the Vedas to India, or the Chinese Classics to Confucianism, or the Zend-Avesta to Zoroastrianism, the Bible is to Christianity. Not that the Bible is to be put on the same level with these other books. Reasons will be given later on in this article to prove the supremacy of the Christian Bible over all other forms of sacred literature.

The Origin of the Term.—The term 'Bible' appears to have been first used in English in catalogues of the 9th and 10th centuries. But the English word is derived from the Greek *ta Biblia* (τὰ βιβλία), a plural form denoting a collection of papyrus rolls, papyrus being the material on which books were written in the early centuries of our era. Though a plural in Greek, the word came, on account of its termination, to be used as a feminine singular in late Latin, and from the Latin it passed over in this form into modern languages—e.g. *la Bible*, *die Bibel*, &c. The term *Biblia* (βιβλία), when used in this connection, was originally qualified by some such adjective as 'holy' or 'sacred' or 'divine'—e.g. the Divine Books; but in course of time the adjective was omitted, and the term 'the Book' or 'the Books' was used by itself, signifying the book *par excellence*, or 'the Book of Books.' The term is never used, of course, in the Bible itself. The contents of the Old Testament are described in the Apocrypha and the New Testament by such phrases as 'the holy books' (1 Mac. xii. 9), 'the book of the law' (1 Mac. i. 56), 'the book of the testament' (1 Mac. i. 57), the 'scriptures' (frequently in the New Testament), 'the holy scriptures' (Rom. i. 2), 'the law and the prophets' (Acts, xxviii. 23), 'the law' (John, xii. 34).

The two Divisions of the Bible.—The Bible is divided into two parts, known respectively as 'the Old Testament' and 'the New Testament.' The term 'Testament' is a mistranslation of a Greek word which means 'covenant.' The relation between God and his people is generally described in the Bible under the form of a covenant. The first covenant is the constant theme of the Old Testament. This covenant, however, proved ineffectual, and the New Testament records how a new covenant which had already been promised to Jeremiah (xxxi. 31) was established through the incarnation and death of Jesus Christ (1 Cor. xi. 25; Heb. viii. 7).

It is a significant fact that the coming of Christ

was regarded as so supreme an event that a clear line of cleavage was drawn between the literature of the preceding age and the literature which was inspired by his life, teaching, and death. Christ is the centre of the Bible. The New Testament is not merely an appendix to the Old Testament: it is the culmination and climax of the revelation of God for which the Old Testament prepares the way.

The Relation between the two Testaments.—Why have we two Testaments, and what is the relation between them? The answers to this question have taken various forms. In early times Marcion and the Gnostics maintained that the two Testaments contained contradictory revelations, and emanated, therefore, from different sources, the Old Testament being the work of the Demiurgus or evil principle in the universe, the New Testament the work of the Supreme God. Such a theory, however, is diametrically opposed to the teaching of the New Testament itself. The New Testament always assumes that the Old Testament is in the same line of revelation as itself. A more common theory has often maintained that the two Testaments are upon the same spiritual level, and contain exactly the same form of revelation. As Augustine put it, 'Novum Testamentum in Vetere latet. Vetus Testamentum in Novo patet.' When it has been impossible to discover the doctrines of Christianity in the plain statements of the Old Testament, resource has been had to the allegorical method of interpretation, and texts have been wrested and distorted into strange meanings. There are traces of this method even in the New Testament, notably in Paul's uses of the allegory of Ishmael and Hagar in the Epistle to the Galatians. It is in the Epistle of Barnabas, however, which deals with the problem of the relation of the two Testaments, that we find the most extreme illustrations of the application of the allegorical method. For instance, Barnabas cites inaccurately the statement of Genesis with regard to the 318 servants of Abraham, and asks what is the significance of this particular number? There must be a mystical meaning, he says, lying behind it. The Greek equivalent for the number 318 is formed of the letters T I H. Now T represents the cross, and I H (H representing E long in Greek) are the first two letters of the word Jesus. The 318, therefore, typifies the death of Christ upon the cross. Equally remarkable is Barnabas's explanation of the law which prohibits the use of certain forms of food. 'Moses spoke with a mystical reference: "Neither shalt thou eat," says he, "the eagle nor the hawk, nor the kite nor the raven." Thou shalt not join thyself, he means, to such men as know not how to procure food for themselves by labour and sweat, but seize on that of others in their iniquity.' It is obvious from these examples that by the adoption of this method it was possible to find in the Old Testament all the doctrines of the New, and put the two books on the same level of spiritual value.

Both these theories as to the relation between the two Testaments are radically wrong. The two Testaments are not opposed to each other, but neither are they identical. It is a travesty of truth and honest exegesis to attempt to find all the doctrines of Christianity in the Old Testament. God's revelation is uniform, but it is progressive. The Old Testament is the preparation for the New. It contains the record of the divine education of Israel to enable it to receive the full and final revelation of God in Christ Jesus. As the author of the Epistle to the Hebrews puts it, 'God having of old times spoken unto the fathers in the prophets by divers portions and in divers manners, hath in these last days spoken unto us by his Son.' The fragmentary revelation of the Old Testament made

the complete revelation of the New Testament possible. 'A revelation ready made and given to man,' says Max Müller, 'like a language formed in heaven, would have been like a foreign religion which men could not understand. . . . If we have any revelation from God at all, we have it at the heart of a great historical development.'

THE OLD TESTAMENT.—*The Purpose of the Old Testament* is, therefore, to prepare the way for the New. Its true function is educative and preparatory. The words which St Paul uses of the law may be applied to the whole of the Old Testament, 'It is a schoolmaster to bring us to Christ.' If it be objected that while it is true that 'natural reason is slow and gradual in its processes,' it is reasonable to suppose that an 'Omnipotent Being will communicate his revelation summarily and by a single act,' we must remember, as Dr Mozley has said, 'when we speak of the Omnipotence of God, we do not mean that he can simply and nakedly do anything that can be stated in words. God can no more force an immediate moral enlightenment upon an existing age and antedate a high moral standard by two thousand years, than he can instantaneously impart a particular character to an individual.' The Old Testament starts with the Hebrew people at the ordinary Semitic level. Their religion is similar to that of other Semitic peoples. It records the story of how they broke away from the common Semitic stock, and in the process of centuries attained to such a high religious development that they became the soil out of which Christianity sprang. There is an infinite gulf, for instance, between the ordinary Semitic conception of God and the conception of God which we find portrayed in the prophecies of Deutero-Isaiah, and that gulf represents the measure of Israel's development, at any rate in one of its aspects. The Old Testament describes the road which had to be traversed before this goal was reached. From beginning to end it is one long *preparatio evangelica*. Nearly every truth taught by Jesus has its antecedents in the Old Testament, and almost every doctrine in the New Testament is shadowed and adumbrated in the Prophets and the Law. As Delitzsch has remarked, 'There is nothing clearly revealed in the New Testament which was not already stirring in the Psalms.' From another point of view, it may be said that the Old Testament stated the problems for which Christianity provided the solutions. The two cries of Job, 'Oh that I knew where I might find him,' and 'How can a man be just with God?' represented the sense of need which the Old Testament had created. Splendid as is the religious development of the Old Testament, it does not lead us to any satisfactory goal, and it ends with a feeling of its own inadequacy. Apart from the New Testament, it leaves us with a sense of unsolved problems, and an unutterable longing for further light and truth.

The Character of the Old Testament.—From what has already been said, it will be obvious that the Old Testament is not a manual of science, or ethics, or doctrine. It is the record of the self-manifestation of God in the history of Israel. Israel was selected out of all the nations of the world to be the channel of God's revelation of himself to mankind. We may assume that the ground for this choice lay in the fact that Israel possessed a native genius for religion. Just as the Greeks were renowned for their artistic instincts and the Romans for their instinct for government, so the Jews seem to have been distinguished for their capacity for religion. The modern discovery of the Tel-el-Amarna tablets and the code of Hammurabi has revealed to us with remarkable vividness the common Semitic inheritance which formed the starting-point

of Israel's development. We know now that much which used to be regarded as original in the Old Testament was really part of the legacy of the prehistoric past. The Old Testament shows how the old traditions were purified and ennobled in the gradual process of Israel's development. We see the steady emergence of new ideas—the change in the conception of God, for instance, the development of the sense of sin and the yearning for forgiveness, the rise of the belief in the advent of a mediator, the slow emergence of the doctrine of the future life.

Estimated by the ordinary standards, there is small ground for pride in the course of Israel's history. Only for a brief period in the time of David and Solomon did it ever attain to any degree of national splendour. Israel was always one of the 'little nations' of the world. For a large portion of its history it formed the buffer state between two great empires, and was constantly being subjected to invasion and devastation. The narrative is one long record of sorrow and catastrophe. But its own national failure was the cause and secret of its spiritual achievement. Its very calamities cast it upon God, and created an intensity of faith which could scarcely have been produced if its history had been more splendid. It was the stress and conflict which followed the return from Egypt that marked the first great step in Israel's religious development, and it was the tragedy of the exile in Babylon that formed its culmination. And it is the work of the Old Testament to show how, in crisis after crisis of the nation's history, the noblest truths of faith were born and grew to maturity.

The Growth of the Literature of the Old Testament.—The Old Testament contains the literature of the people of Israel during some six or seven hundred years of the nation's history. The 8th, 7th, and 6th centuries B.C. were the really creative periods: what literature existed in the pre-prophetic period, and what form it assumed, is more or less a matter of conjecture. We know that collections of lyrical poems had been made in earlier times, for quotations taken from them have been incorporated in our historical books. 'The Book of the Wars of Yahweh,' cited in Numbers, xxi. 14, 15, and 'the Book of Jashar,' quoted in Joshua, x. 12-13, seem to represent two such collections. The best specimens of this early poetry are to be found in the song of Deborah (Judges, v.), the elegy for Saul and Jonathan (2 Sam. i. 17), the song of the well (Num. xxi. 17, 18), the sword-song of Lamech (Gen. iv. 23, 24), the song of Moses at the Red Sea (Exodus, xv.), &c. We know, too, that some attempts at historical writing were made in the pre-prophetic era. Certain of the sources used in our existing historical books must have been in existence from very early times. J and E—two of the most important documents out of which the Pentateuch was constructed—must have been written before 750, and may possibly have been as early as 900 B.C. (See BIBLICAL CRITICISM.) But it was not till the last half of the 8th century that this literature began to take shape in anything like the form in which we possess it to-day. *Between 750 and 700* the first great outburst of literary activity occurred. To this period belong Amos, c. 750; Hosea, c. 745-735; Isaiah, 740-690; Micah, 720-708. The Books of Samuel, too, must have been composed substantially in their present form before 700. The next half-century is comparatively barren from a literary point of view, but *between 650 and 586* (the date of the fall of Jerusalem) we have another outburst of prophecy—e.g. Zephaniah, c. 630-605; Nahum, c. 625; Habakkuk, c. 605; Jeremiah, c. 626-586; Deuteronomy in its earliest form, c. 621; and the Book of Kings, c. 600. *The period of the exile (586-538)* was also very productive.

To this period belong Ezekiel, c. 592-570; Deutero-Isaiah; Lamentations, c. 540; and certain parts of the Psalter. To the century which followed the return from the exile, 538-444, belong the Priestly Code; Haggai, c. 520; Malachi, c. 450; parts of Zechariah, 520-518. In this period the Pentateuch was constructed out of J E P D. Chronicles, Ezra, and Nehemiah belong to the *period 300-250*—possibly also Canticles and Ecclesiastes. Esther was a later production, though its exact date seems difficult to fix. Daniel was written about 168, and finally the Psalter was completed about 150.

The Formation of the Old Testament Canon.—Literature is one thing; a Bible is something very different. A Bible implies that the books in its canon are in some way divinely inspired, and contain the message of God to his people. Obviously the contents of the Old Testament do not exhaust the literature of ancient Israel. There are writings, for instance, like the Book of Enoch, which never obtained a place in sacred scripture. When, and under what circumstances, was the collection of books which form the Old Testament first made? The formation of the Old Testament canon was a process, and not an event. It grew up gradually, and five hundred years elapsed between the beginning and the completion of the process. The Old Testament consists of three well-marked divisions: (1) *the Law*, a term which was used to describe the Pentateuch, or rather the Hexateuch, for the Book of Joshua was always closely associated with the Pentateuch; (2) *the Prophets*, a division which includes not merely the prophetic writings, but the earlier historical books as well—e.g. Judges, 1 and 2 Samuel, and 1 and 2 Kings; (3) *the Kethubim* or *Hagiographa*, a collection of miscellaneous writings—Psalms, Proverbs, Job, Ezra, Canticles, &c., in fact all the books of the Old Testament which have no place in the two earlier groups. Now, these three divisions mark three vital stages in the formation of the canon. The earliest Jewish Bible consisted only of the Hexateuch. In fact the Samaritan Bible, which seems to have stereotyped this stage in the development, contains only the Pentateuch. The second Jewish Bible was formed by the addition of the section known as the Prophets, and the third Bible—representing our present Old Testament—is the second expanded by the insertion of the books known as the Hagiographa.

When were these three different canons formed? We can be certain that the first canon—the Hexateuch—was constituted at the end of the 5th century B.C., somewhere between 444 and 400 B.C. In the year 444 B.C. the solemn assembly which is described in the ninth chapter of the Book of Nehemiah pledged itself to 'the book of the law of Yahweh their God.' Whether the book alluded to is our Hexateuch, or merely the Priestly Code, cannot be determined with certainty; but we may be sure that even though the reference may be limited to the Priestly Code, yet well within the limits of the century this code was incorporated in the collection J E D (see PENTATEUCH), and directly the incorporation had taken place the whole of the Hexateuch would naturally assume the place of dignity and honour in the popular esteem which had been assigned at first to the Code. The time when the *second division* of the canon was made is more difficult to fix. We have good grounds, however, for thinking that it must have been added before 200 B.C. The author of the Book of Sirach, writing in his prologue about 130 B.C., says: 'Whereas many and great things have been delivered unto us by *the Law and the Prophets*, and by others that have followed in their steps, . . . my grandfather, Jesus, when he had much given himself to the reading of *the Law and the Prophets*

and other books of our Fathers, and had gained therefrom good judgment, was induced also himself to write something pertaining to wisdom and learning.' The date of the grandfather may be fixed approximately at 180 B.C. We see, therefore, that by 180 B.C. the second division of the canon was well established, and other writings besides were beginning to come into consideration. The third division of the canon was gradually added during the period 200 B.C.-90 A.D. As we have already seen, at the time when the prologue to Sirach was written (130 B.C.) other books were beginning to be ranked with the Law and the Prophets. And we know that at even an earlier date, when the main body of Sirach was written (180 B.C.), the author drew upon some of the Hagiographa (e.g. Chronicles, Ezra, and Nehemiah) for the information contained in his chapters on the 'praise of famous men.' In the New Testament several of these later books (e.g. Psalms, Proverbs, Job, and Ecclesiastes) were cited as Scripture. The fourth Book of Ezra (90 A.D.) regards the whole of the contents of our present Old Testament as canonical, and so probably does Josephus (90 A.D.). The authoritative settlement of the canon was made at the Jewish Synod of Jamnia in 90 A.D., when the Old Testament became established in the form in which we possess it at present. The decree of the Council of Jamnia did not, however, at once secure universal acceptance. For some time there was hesitation about the acceptance of Canticles and Ecclesiastes, which were the two last books to secure canonicity. And even as late as 170 A.D. Melito, the Christian bishop of Sardis, felt himself unable to specify the exact contents of the Old Testament till he had visited the country in which these books had originated and investigated the matter for himself. Still, for all practical purposes, we may say that, as far as Palestine was concerned, the canon of the Old Testament was authoritatively settled by the Synod of Jamnia. If we ask the reason why a process of evolution which had been going on for five hundred years was suddenly brought to an end, the answer is to be found in the fact of the fall of Jerusalem, which resulted in the destruction of the Temple. Before 70 A.D. the Temple had been the centre and soul of the Jewish religion. When its Temple was destroyed, it had to find a new centre, and it turned to its sacred writings. From this time onwards the Bible took the place of the Temple, and Judaism became the religion of a book. We may be fairly confident that had it not been for the destruction of Jerusalem the Old Testament canon would not have been stereotyped at so early a date, nor would the book have obtained so dominant a place in Jewish religious life.

The Alexandrian Canon.—But if the process of the evolution of the canon was arrested in Palestine by the Synod of Jamnia, it still continued in Alexandria. In Alexandria a fourth division was added, containing the books now known as the Apocrypha (see APOCRYPHA). These writings may be classified as follows: (1) *Historical Books*—1 Esdras, 1 and 2 Maccabees; (2) *Didactic Works*—The Wisdom of Solomon, the Book of Sirach (Ecclesiasticus); (3) *Religious Romances*—Tobit and Judith; (4) *Prophetic or Apocalyptic Works*—Baruch and 4 Ezra; (5) additions to the Old Testament—e.g. to Esther and Daniel. All these works (with the exception of 4 Ezra) are found in the Greek version of the Old Testament known as the Septuagint. The Apocrypha, therefore, represents the difference between the contents of the Hebrew Bible and the Septuagint plus 4 Ezra. The controversy with regard to the Apocrypha is a conflict between the Palestinian and Alexandrian canons. Up to the time of the Reformation, in spite of a few protests, the Alexandrian canon was generally ac-

cepted by the Christian Church, and the Apocrypha regarded as an integral part of Holy Scripture, and that position was authoritatively adopted for Roman Catholicism by the Council of Trent. In Protestantism, however, a return was made to the Palestinian canon, though the additions made by Alexandria were often accepted as 'an example of life and instruction of manners.' Had not the destruction of Jerusalem precipitated the completion of the canon in Palestine, there is little doubt that this fourth division would have gradually won recognition, and now be occupying an unchallenged place in the Old Testament.

The Language and Text of the Old Testament.—The Old Testament was written in Hebrew, with the exception of certain parts of Ezra and Daniel, which are in the vernacular Aramaic. Originally written Hebrew consisted purely of consonants, the vowels being mentally supplied by the reader. It was not till the 6th century of our era that vowel signs were introduced into the text. The absence of vowels left the door open for confusion and misinterpretation, and it was to avoid this that a school of Jewish scholars, known as the Massoretes, between the 5th and 8th centuries of our era, undertook the vocalisation and standardisation of the Hebrew text. The Hebrew text in use to-day is the result of their labours, and is called Massoretic. Our earliest complete Hebrew manuscript dates probably from 916 A.D., which is 550 years later than the earliest MS. of the New Testament. We have, therefore, to face the fact that there is an interval of 1600 years between the time of Amos and our earliest record of his writings, and an interval of more than 1000 years between the composition of the latest book in the Old Testament—probably Daniel—and our earliest Hebrew MS. Our Hebrew MSS., it is true, are in singular agreement with each other, and do not exhibit anything like the number of variant readings which we find in New Testament MSS.; but that is only because they are all of them comparatively late, and based upon the standard text of the Massoretes. That corruptions had unfortunately crept into the Hebrew text before the Massoretic scholars took it in hand is, unfortunately, only too evident. If we compare Psalm xviii., for instance, with the version of the same hymn which we find in 2 Sam. xxii., we become conscious of a large number of variations and differences in the two texts, most of which must be due to mistakes on the part of a copyist. Then, too, there are cases where the Hebrew text is absolutely unintelligible. For instance, in 1 Sam. xiii. 1 we find the extraordinary statement, 'Saul was a year old when he began to reign, and he reigned two years over Israel.' This statement is palpably absurd. Something has obviously gone wrong with the text, probably owing to an accident in copying. It is unfortunate that in the case of the Old Testament, as the Revisers remind us in the preface, 'the Received or, as it is commonly called, the Massoretic text has come down to us in manuscripts which are of no very great antiquity, and which all belong to the same family or recension.' Most modern Hebraists maintain that the existing MSS. of our Old Testament are derived from a single MS. of a date not earlier than the 1st or 2d century of our era. This means that since we have representatives of only one recension, we have no available data in Hebrew for applying the principles of textual criticism to the Massoretic text. Fortunately, however, we possess the Septuagint (see SEPTUAGINT) or Greek translation of the Old Testament, the earliest parts of which belong to the 2d, possibly the 3d, century B.C., and which, therefore, was based upon an earlier Hebrew text than we possess in our available MSS. By the use of the Septuagint

we are able to reconstruct this Hebrew text and use it as a criterion for testing the accuracy of our own Hebrew MSS. We have, however, to make many allowances. The Septuagint translation may not be, indeed often it is not, an accurate rendering of the Hebrew, and sometimes we are not able to discover with any degree of certainty what the original Hebrew text actually read. Still, there is no doubt that when scientifically applied the judicious use of the Septuagint is of immense value in correcting obvious mistakes and providing an explanation of difficult passages. Three revised versions of the Septuagint were made in the early Christian centuries by Aquila, Symmachus, and Theodotion respectively, but, unfortunately, only fragments of these have survived. It is interesting to remember that in the year 240 A.D. Origen made an attempt to provide material for constructing a scientific text of the Old Testament in his *Hexapla*. In the *Hexapla*, in six parallel columns, Origen put side by side (1) the Hebrew text, (2) the transliteration of the Hebrew text into Greek letters, (3) the Septuagint, (4) Aquila, (5) Symmachus, and (6) Theodotion. Other versions of the Old Testament also exist—e.g. the Syriac, the Latin (especially Jerome's translation, known as the Vulgate), the Coptic or Egyptian versions, the Targums or Aramaic paraphrases of the Old Testament—but these are mostly of a later date, and assume the Massoretic text, and so are not nearly as valuable for the purposes of textual criticism as the Septuagint.

The Permanent Value of the Old Testament.—If the Old Testament is simply preparatory, if it represents merely the education of the Jewish people for the reception of Christianity, if it has been superseded by the New Testament, why should it be still retained as part of the Christian Bible? This question was raised in an acute form by Professor Bury in his *History of the Freedom of Thought*. 'It was unfortunate,' he says, 'that the early Christians included in their scripture the Jewish writings which reflect the ideas of a low stage of civilisation, and are full of savagery. It would be difficult to say how much harm has been done, in corrupting the morals of men, by the precepts and examples of inhumanity, violence, and bigotry which the reverent reader of the Old Testament, implicitly believing in its inspiration, is bound to approve. It furnished an armoury for the theory of persecution. . . . Christianity, by adopting books of a long-past age, placed in the path of human development a particularly nasty obstacle' (pp. 53, 54). Such an argument as this seems to be wilfully blind to the great and permanent contributions which the Old Testament made to Christian thought. If we were to confine ourselves merely to those parts of the book which represent the lower and more primitive stages of the religion, there would be something in Professor Bury's position; but when we come to the higher regions of Old Testament thought, we instinctively feel that Christianity would be irreparably poorer if it were deprived of the lofty spiritual feeling of the Psalms, the strong ethical note of the Prophets, the wise statements of the Book of Proverbs, and the soul-strivings of the Book of Job. We must never forget that Jesus nourished his soul upon the Old Testament, and used it frequently in his teaching. The theology of St Paul is simply saturated with Old Testament ideas. If Jesus and the Apostles and the early Church found the Old Testament a source of inspiration and illumination, if much that is best in their teaching is drawn from this source, it would be a disaster for the modern Church lightly to set aside a book on which its founder and first leaders have set their seal. The essence of the Old Testament teaching was assumed

to be part and parcel of the Christian faith. If the Old Testament had not already been in existence, the New Testament must have taken a very different form.

Moral Difficulties in the Old Testament.—There are, of course, some moral difficulties in the teaching of the Old Testament, and it is to these that Professor Bury is specially referring. The sacrifice of Isaac, and Jephthah's vow, for instance, have always been regarded as difficult to reconcile with the spirit of Christianity. Then there are cases in which altogether disproportionate punishment seems to have been inflicted by God upon offenders—e.g. on Nadab and Abihu for offering the wrong kind of incense (Num. iii. 4). The murder of 50,000 people for looking into the ark seems also difficult to square with a true conception of Christian charity (1 Sam. vi. 19). The command to exterminate the Canaanites, too, was an extreme military inhumanity, to say the least (Deut. xx. 17). Then there are the imprecatory Psalms, in which the psalmist prays in no measured terms for vengeance to be exacted upon his enemies (Psalms, vii., xxxv., lxix., lxxix., cx.). What are we to say with regard to these elements? It is quite clear that the modern mind, if it is at all imbued with the spirit of the New Testament, cannot accept them as part of a divine revelation. There are some considerations, however, which serve to mitigate what seems to be a flagrant contradiction between the moral teaching of the Old Testament and that of the New upon such points as we have mentioned. Firstly, we must remember that the Old Testament is the record of the slowly evolving revelation of God. Obviously these moral defects belong to the beginning of the process, and not to the end. When they occur in the later books, we must regard them as the recrudescence of an earlier spirit which had not yet been completely mastered. Then, secondly, we must never forget that the divine revelation in the Old Testament was manifested through fallible men, and, as Dr Bennett has put it, 'there was room for an imperfect understanding of the divine communication.' Prophets and psalmists were subject to limitations of character, knowledge, and sympathy, and sometimes they may have mistaken human prejudice and vindictiveness for the teaching of God. It would be a fatal mistake, however, to ignore the greatness and grandeur of their message because at times they have confused human passions with divine inspiration.

The Religious Value of the Old Testament.—The value of the Old Testament lies in the importance of the contributions which it has made to our knowledge of God and the relations between God and man. It is this that gives it—next, of course, to the New Testament—a supreme place in the sacred literature of the world. There is nothing in the Vedas or the Koian or the Analects of Confucius or the Zend-Avesta to compare with the sublime conception of God which we find in the pages of Deuterio-Isaiah. Other nations have attained, of course, to some form of monotheism, but not to so pure and ethical and universal a monotheism as we find at the climax of Old Testament thought. The God of the later prophets is omnipotent ('All nations before him are as nothing') and holy, but he is tender and compassionate and benevolent as well ('Like as a father pitieth his children, so the Lord pitieth them that fear him'), and it is this combination of attributes that constitutes the greatest contribution of the Old Testament to theology. When we remember that the Hebrews started simply with a tribal deity, with few, if any, ethical qualities, the achievement becomes all the more remarkable. Such a development is absolutely unique in the history of

religion. Then, too, the evolution of the sense of sin, which is the natural counterpart of the doctrine of God, is such as we can scarcely find a parallel to elsewhere. The problem of suffering, moreover, which is the despair of most religions and philosophies, receives a most unique and sympathetic treatment in the pages of the Old Testament, and if no real solution is found, there are manifold hints and suggestions which bring comfort and relief to the baffled soul. That the Old Testament did hold out a very lofty moral ideal, and create a very high type of spiritual life, the devotional hymns in the Psalter afford sufficient proof. There is nothing in any other sacred literature to match the confidence and the faith and the unquenchable hope, even in the face of national and private calamities, which are evinced in most of these sacred poems, and it is these elements which have given the Psalter a permanent primacy among books of devotion. Then, too, the belief in the infinite value of the individual to God, which marks the later stages of Old Testament thought, is a unique contribution to faith and theology. The dim conception of a future life in the greater part of the Old Testament is sometimes regarded as a defect, but we must never forget that before the Old Testament closes that belief has become one of the strongest articles in its creed.

Social and Ethical Teaching.—Jesus summed up the whole duty of man in the words, 'Thou shalt love the Lord thy God with all thy heart, . . . and thy neighbour as thyself,' and these words represent not merely the language but the spirit of the ethical teaching of the Old Testament. There is much in the Levitical law, of course, that seems puerile and trivial to-day, but the motives and principles that lay behind these enactments are altogether beyond criticism. Huxley said of it, 'There is no code of legislation, ancient or modern, at once so just and merciful, so tender to the weak and the poor, as the Jewish law.' And in the prophets, too, the ethical note is always predominant. There is no divorce in Judaism between morality and religion. In the Old Testament, as in no other sacred literature, morality is made an integral part of religion. Then, too, few codes are drawn up with such a direct sympathy with the interests and needs of the poorer classes. The institution of the year of jubilee, for instance, provided that land which had been sold was to be returned every fifty years to the family which had originally owned it. The object of this provision was obviously to prevent the land getting into the hands of a few landowners; and if the enactment had been carefully carried out, many abuses would have been prevented. The prophets are continually protesting against the avarice of the rich in this matter. 'Woe unto those,' says Isaiah, 'who join house to house, who add field to field, till there is no more room, and ye are settled in the midst of the land' (v. 8). Micah is equally vigorous in denouncing men who 'covet fields and seize them, who covet houses and appropriate them' (ii. 2). Ezekiel, too, protests against the social conditions of his times and the oppression of the poor by the rich (cf. xxxiv. 18); and the Book of Job denounces in no measured terms the evil of 'sweating' (xxiv. 10). The burden of the teaching of the prophets is that the nation is responsible for the welfare of the people, and must act as the protector of the poor and oppressed.

The Old Testament as History.—One of the most unique features of the Old Testament—and it is a feature which is not found in the same degree anywhere else—is its insistence upon the fact that history is teleological, and that throughout its course and movement God is working out an eternal purpose for the world in general, and for his

chosen people in particular. It is not too much to say that the Old Testament is the first great philosophy of history, and that no subsequent philosophy of history has ever superseded it. It is this characteristic that helps to give to the Old Testament its supreme value. The Old Testament is far more than a storehouse of historical facts; its greatness lies rather in the interpretation which it puts upon those facts, and its recognition of the presence of the 'unseen hand' of God behind all the events of history, shaping and moulding the destinies of nations.

When we come to consider the question as to the value of the narrative in the Old Testament, the record has, of course, to be tested by the recognised canons of historical research, and we must not be surprised if, as the result of the investigation, it is necessary to assign different degrees of validity to different parts of the story. The narrative of the history between 750 B.C. and 550 B.C. is quite the most reliable. For this period we have an abundance of contemporary documents, especially in the prophetic literature. We may be tolerably confident, too, about the general accuracy of the Davidic period, because, though the Books of Samuel in their present form are considerably later, they made use of sources which go back to a much earlier date. But when we work back into the remoter periods, there is more room for doubt. Our earliest narratives (J and E of the Pentateuch) are, on the most conservative calculation, at any rate 300 years later than Moses and more than 1000 years later than Abraham. There seems, however, good ground for supposing that the general picture of Moses is substantially true, because the later history of Israel cannot be explained apart from the facts which are recorded in the Book of Exodus. When we come to the patriarchal period, however, we are on ground that is much less sure, and there is the utmost diversity of opinion among modern scholars as to whether the patriarchs are to be regarded as real historical personages, or merely mythical figures representing certain early tribal movements. Two representative opinions may be quoted. Dr Skinner, in the *International Critical Commentary on Genesis*, writing of Abraham, says: 'Nothing forbids us to see in Abraham the first of that long series of prophets through whom God has communicated to mankind a saving knowledge of himself. . . . As we read the story, we may well trust the instinct which tells us that here we are face to face with a decisive act of the living God in history, and an act whose essential significance was never lost in Israelite tradition.' Dr Bennett, on the other hand, says: 'There is a marked contrast between the Moses and the Abraham narratives in the earlier documents. The latter do not seem to ascribe to Abraham national significance as an outstanding personality who moulded the political and religious future of his people. His adventures are rather those of the typical nomad or seminomad.' He concludes that the narratives of Genesis represent 'domestic folklore rather than reminiscences of an epoch-making prince and prophet.' One of the best discussions of the subject is to be found in Dr Bennett's article on 'The Historical Value of the Old Testament' in the volume of *London Theological Studies*.

THE NEW TESTAMENT.—*The Links between the two Testaments.*—Though the Old Testament was not definitely canonised in its present form till after the earliest New Testament documents had been written, yet there is a gap of about 200 years between the writing of the last book of the Old Testament and the first book of the New. These two centuries were not a period of silence. There was no cessation in God's dealings with his people,

no hiatus in the divine preparation for the advent of the Messiah. The Books of Maccabees relate the story of the heroic struggle for freedom which gave once more to Israel the sense of its nationality. As Westcott puts it, 'The Maccabees inspired a subject-people with independence; they found a few personal followers, and they left a nation.' *The Book of Wisdom*, written about the commencement of the Christian era, by its speculations with regard to Wisdom and the Logos as attributes of God, helped to provide the categories for the Christian interpretation of Christ. There can be no doubt, for instance, that the language which is used to describe Christ in the opening verses of the Epistle to the Hebrews was freely borrowed from it. *The Testaments of the Patriarchs* (109-107 B.C.), which contains a series of ethical tracts for the times, certainly influenced the thought of St Paul, and some resemblances have been pointed out between its teaching and that of Jesus. *The Book of Enoch*, which in its present form is a composite document, contains in the section known as 'the Similitudes' (which dates from the first half of the 1st century B.C.) a portrayal of the Messiah, whom it describes as 'the son of Man' 'seated at the right hand of the throne of God'—a conception which transcends the Messianic ideas which we find in the Old Testament. *The Assumption of Moses* (between 1 and 30 A.D.) anticipates the teaching of Jesus upon Quietism. Further Messianic ideas appear in *the Psalms of Solomon* (between 70 and 40 B.C.), *the Apocalypse of Baruch* (between 50 and 100 A.D.), *the Ascension of Isaiah* (80 and 100 A.D.), and *the fourth Book of Ezra* (after 70 A.D.), but in the case of the three latter books they may possibly (though this is not probable) have been suggested by Christian influences. It is impossible to give any real impression as to the vast effect which this intermediate literature produced upon the New Testament. The New Testament must inevitably have been a very different book if the writers had not been steeped in the teaching and spirit of these writings. And it is no exaggeration to say that New Testament study has been simply revolutionised in modern times by the discovery and publication of the Jewish apocalyptic writings. 'It is,' as Sanday and Headlam say in their *Commentary on Romans*, 'by a continuous and careful study of such works that any advance in the exegesis of the New Testament will be possible.' The publication of an annotated translation of this literature in the Oxford *Apocrypha and Pseudepigrapha* (1913) has now for the first time placed the available materials in the hands of students in a convenient form.

The Character of the New Testament.—The New Testament is the inspired literature of early Christianity. It consists of three different types of books: (a) The Historical Books—viz. the four Gospels and Acts—which give an account of the life and teaching of Jesus, and of the development of the primitive Church from its foundation in Jerusalem to the arrival of St Paul in the city of Rome; (b) the Epistles, which represent the correspondence of St Peter and St Paul and other leaders of the apostolic age with different churches or groups of Christians: it is in these epistles mainly that the doctrinal position of the Christian religion is developed; (c) Prophecy or Apocalyptic, represented by the Book of Revelation, which describes the Christian eschatology, and portrays the events which the Church believed would take place before and at the termination of human history by the return of Christ.

The whole of this literature, diverse as it is in form and outlook, is animated by one spirit and dominated by one theme. Christ is the centre and soul of every book. His teaching and his great

act of redemption, his person and the saving grace which he came to reveal, form the basis and foundation on which every utterance in the New Testament rests. There are different types of theology, different modes of expression, different interpretations of the Christian facts, but the acceptance of Jesus Christ as the Son of God and the Saviour of the world is the great assumption that lies behind every document in the New Testament.

The Origin of the New Testament Literature.—Jesus himself left no writing behind him. The correspondence with Abgarus, which later ages attributed to him, is universally recognised as a forgery. In the beginning of things, therefore, it was not the New Testament that created the Church: it was rather the Church that created the New Testament. Judged by ordinary standards, the New Testament came into existence in a haphazard way, though doubtless behind the causes that produced it there was always the working of the Spirit of God. We cannot be absolutely certain which was the earliest document to be written, but we know that it must have been an epistle. There are three claimants for the position—the Epistle of James, 1 Thessalonians, and Galatians. It was the needs and circumstances of early missionary work that led to the writing of the Epistles. The Christians of different churches needed to be encouraged; the problems and perplexities which beset both faith and practice in early times needed to be dealt with; erratic tendencies in thought and life needed to be corrected; the advice of the founder was often sought on matters of difficulty which inevitably arose in the development of new communities; controversies emerged in which it was necessary for an apostle to intervene. And it was to meet the needs of the situation in the churches, which had been created by their successful missionary labours, that St Paul and other leaders of the Apostolic Church first took to writing letters, generally to communities, but sometimes to individuals. These epistles were written in view of the problems and difficulties of the 1st century, and the writers had no idea that their letters would ever form part of a New Testament. If this thought had occurred to them, we may be sure that these letters would have assumed a very different form.

The Gospels were written to meet the needs of the second generation of Christians, and especially of those who lived in the Gentile world, far removed from authentic sources of information with regard to the facts of the life of Christ. Probably the earliest demand was for some authoritative statement of the teaching of Jesus for the use of new converts and others who had not themselves had an opportunity of listening to his own words or the benefit of instruction from the apostles. The first attempt to satisfy this demand is found in the document known as Q, which is now incorporated in the Gospels of St Matthew and St Luke. The earliest gospel—St Mark—was written for Gentile Christians, more particularly for those who lived in Rome. The first and third gospels were a compilation from these two sources, with additional material gleaned from elsewhere, St Matthew being written for Jewish, St Luke for Gentile, Christians. Finally, the explanation of the cause which produced the Book of Revelation is not difficult to find. The atmosphere during the latter part of the 1st century was full of apocalyptic ideas, many of which specially appealed to the Christian imagination. Men could not fail to ask, Is there not a place in Christianity for the apocalyptic hope? What has Christianity to say about eschatology? It was to answer such questions as these that a Christian writer in the reign of

Domitian appropriated the best apocalyptic material which he could find and suffused it with the Christian spirit.

It took a hundred years—that is, if we follow modern criticism and place 2 Peter about 150 A.D.—to create the literature of the New Testament, though it is only fair to add that by far the greatest part of it was produced between 50 and 100 A.D.

The Formation of the New Testament Canon.—The canon of the New Testament is composed of books which were regarded as inspired by God to be the guide of men in matters of faith and life. We have seen how the literature arose. The question we have to consider now is, When did these books come to be regarded as Scripture and take rank side by side with the Old Testament? We can discuss the question best if we divide the history of the early Church into the following periods: (1) 70–135, (2) 135–170, (3) 170–210, (4) 210–400, and consider the treatment of the New Testament books in each. In the *first period* there is no suggestion of the formation of a New Testament. There are allusions to some of the epistles—to 1 Corinthians in Clement of Rome and to Philipians in Polycarp—and quotations are made from other epistles, but there is nothing to show that they were regarded as Scripture. In the *second period* some real progress is made. The Gospel of St Matthew is cited as Scripture (and this is the earliest application of the word to any of our New Testament books) in the so-called second Epistle of Clement, which is generally dated about 150. More striking testimony still is to be found in Justin Martyr (c. 150). In describing the worship of his time Justin says: 'On the day called Sunday all who live in cities or in the country gather together to one place, and the memoirs of the apostles or the writings of the prophets are read as long as time permits.' There can be no doubt as to the meaning of the term 'memoirs,' because Justin himself adds the explanation, 'the memoirs of the apostles which are called gospels.' Thus we see that in the time of Justin the gospels were used in public worship side by side with the prophets. In this period we find the first attempt to create a canon made by Marcion the Gnostic (c. 140). Marcion's canon consisted of the Gospel of St Luke (in an abbreviated form) and ten Epistles of St Paul, which he also mutilated to suit his own views. The *Diatessaron* of Tatian (c. 160), which is a harmony of the four gospels, is a further piece of evidence as to the place which the gospels had already won in the esteem of the Church. We may therefore say that in this period the canon began to shape itself as far as the gospels and the Pauline epistles are concerned. It is the *third period*, however (170–210), that is really creative. To this period belongs the Muratorian Fragment, which is the first formal Christian attempt to construct a New Testament canon. The Muratorian Fragment gives a list of the books which were in general use in the Christian Church, with a brief account of the origin and authorship of each. We have also the evidence of the three great Fathers who flourished at the end of the 2d and the beginning of the 3d century—Irenæus, Clement of Alexandria, and Tertullian—whose writings represent the recognised opinion of the time. From this evidence, as also from the evidence of the Old Latin and Syriac versions, we obtain incontestable proof that the bulk of the contents of our present New Testament was universally accepted as Scripture at this time—viz. the four Gospels and Acts, the thirteen Epistles of St Paul, 1 Peter, and 1 John. 'No one will deny,' says Westcott, 'that these books occupied the same position in the estimation of Christians in the time of Irenæus as they hold now.'

The remaining seven books of the New Testament—i.e. Hebrews, James, Jude, 2 John, 3 John, 2 Peter, and the Book of Revelation—are not so well authenticated. There is strong testimony in favour of most of them, but the testimony is not unanimous. James and Hebrews were recognised in the Eastern division of the Church, but do not seem to have been generally used in the Western, since they are found in Old Syriac but not in the Old Latin versions. Moreover, they are absent from the Muratorian Fragment. 2 John, 3 John, and Jude, on the other hand, seem to have been recognised in the West, since they are included in the Latin versions and the Muratorian Fragment, but not in the Syriac versions; the Apocalypse is partially recognised in both divisions of Christendom, but some doubt is thrown upon the Johannine authorship. There is as yet no trace of the use of 2 Peter at all. So that in this period we have really two canons, an *Eastern*, containing the four Gospels and Acts, thirteen Epistles of Paul, 1 Peter, 1 John, Hebrews, and James, and possibly the Apocalypse; and a *Western*, containing the four Gospels and Acts, thirteen Epistles of Paul, 1 Peter, 1 John, 2 John, 3 John, Jude, and possibly the Apocalypse. In the *fourth period* these two rival canons gradually began to coalesce, though it was some time before absolute unanimity was reached. Origen, writing about 250, regards 2 Peter, 2 John, 3 John, and probably James and Jude, as 'doubtful books,' and even in the time of Eusebius (325) the doubt still remained. There was a good deal of hesitation, too, about the Apocalypse. Athanasius and Epiphanius were the earliest Fathers to recognise a New Testament identical with our own. The other Fathers of the 4th century generally omitted the Apocalypse. It was not till the end of the 4th century that, under the influence of Augustine and Jerome, official sanction was given to our present New Testament canon at the Synods of Hippo (393) and Carthage (397). But even the decision of these councils did not altogether dispel the doubt about the Apocalypse, and it was not till some centuries later that it obtained an unchallenged place in the New Testament canon.

Other Books which were at one time regarded as Scripture.—In addition to the books which now form the New Testament, there were others which were for some time on the borderland, and which many people thought ought to have been admitted to the canon. The *First Epistle of Clement*, for instance, was publicly read in church right up to the time of Eusebius. The *Didache*, or Teaching of the Apostles, is quoted by Clement of Alexandria as Scripture, and mentioned by Athanasius in his list of 'sacred writings.' The *Epistle of Barnabas* is actually included in one of the earliest and most valuable MSS. of the New Testament—the Sinaitic—where it follows immediately after the Book of Revelation. Origen, too, describes it as a 'catholic epistle,' and cites it as Scripture. The *Shepherd of Hermas* seems to have been more popular still. It is included not only in the Sinaitic MS. of the New Testament, but in several other MSS. as well. Irenæus quoted it as Scripture, Origen regarded it as 'divinely inspired,' and Eusebius tells us it used to be read in public worship. On the whole, however, we are bound to admit that the Church has not suffered greatly by the omission of these books from the canon. They are all of them interesting and valuable as literature, but they have none of them the same spiritual value or the authentic note of revelation which characterises the recognised books of the New Testament.

The Language of the New Testament.—The New Testament was originally written in Greek. The particular type of Greek employed has, however,

been for centuries a puzzle to scholars, and it is only quite recently that its explanation has been found. It differs so profoundly not only from classical Greek, but from the ordinary literary Greek of its own age, that no satisfactory account could be given of it till the discovery of the papyri revealed the fact that it represented the vernacular speech of the day. The New Testament is written in the common tongue of the people—the language of the market-place and of the home. As Von Soden has said, 'The Christians did not create, as was once thought, a peculiar dialect of their own. Nor did they speak and write, as others have believed, in a Jewish-Greek patois. There is a difference between New Testament Greek and that of other contemporary writers. But this distinction does not lie in distinction of dialect. The latter authors, who wrote for a cultured public, endeavoured to imitate that epoch of the language which had been consecrated by the classic creations of the Periclean age. The Christian writers, free from all such æsthetic humours, spoke in the living language of their time, in that popular language of conversation and commerce as it again lives before our eyes in the epistles and commercial records which the sands of Egypt have preserved for the enterprising excavator of to-day.' But even within the New Testament itself there are varieties of style. The best Greek is found in the Epistle to the Hebrews and in the writings of St Luke. In point of style these books are not inferior to the contemporary literature of the time. St Paul, too, is a great master of the Greek tongue. 'The Greek of those days becomes in his hands the keenest and most flexible instrument of a spirit of boundless power and endowment.' The smallest amount of linguistic skill is found in the Johannine writings, more particularly in the Book of Revelation.

The Text of the New Testament.—The problem of textual criticism is to get back to the actual words of the original autographs of the New Testament books. Our earliest Greek MS. dates from the middle of the 4th century—some three hundred years after the earliest document was written—and the received text was based on MSS. of a much later date. It is inevitable that in the process of copying and recopying some corruptions must have got into the text. Moreover, when we come to collate the different MSS. we become conscious at once of an infinite number of variant readings. How can we determine, when our authorities differ, what was the original reading of the autograph? In the first place, it is necessary to examine and classify our material. This material, fortunately, is superabundant. (1) We possess more than 3000 Greek MSS. of the New Testament. They are divided into two classes. Firstly, we have a small group of uncials, so called because they are written in capital letters without any break between the words. The earliest and most valuable of these are (a) the Codex Sinaiticus at Petrograd (4th century, commonly known as α); (b) the Codex Vaticanus at Rome (4th century, known as B); (c) the Codex Alexandrinus in the British Museum (5th century, known as A); (d) the Codex Bezae at Cambridge (6th century, known as D). Secondly, we have a large mass of cursives, so called because they are written in a smooth, running hand. These are of considerably later date, and therefore of much less value. (2) Besides the actual MSS., we possess a large number of quotations in early Christian writers—e.g. Irenæus, Tertullian, Cyprian, Origen—from which we are able to discover the particular form of text which was used in their time. (3) We have also the versions or translations of the New Testament into Latin, Syriac, Coptic, some of which were made at a very early

date, and are much earlier than our most ancient Greek MS.

It is by the scientific examination of these data that we are able to get back behind our earliest MSS. and reconstruct the text which was used in the 2d and 3d centuries. As a result of this process of investigation we find that four types of text are represented in our Greek MSS. and versions. (1) A Syriac text, which is the latest of the four, and does not seem to have been current till the 5th century. This form has been preserved in what is known as the *textus receptus*. It is the text which is found in the mass of later MSS. (2) The Alexandrian text, which is represented, partially at any rate, by Codex A and the quotations in Origen. (3) The Neutral text, which has the support of Codices κ and B and the Bohairic version. (4) The Western text, which is found in Codex D, the Old Latin, and the Old Syriac versions. The modern alternative lies between the two last types. Westcott and Hort in their epoch-making reconstruction of the New Testament text followed almost entirely the Neutral type. They attached supreme importance to the evidence of Codices κ and B, and maintained that when these two MSS. are in agreement their testimony outweighs in value all other evidence. The recent trend of textual criticism, however, is towards the rehabilitation of the Western text, and much more importance now is attached to the evidence of the Old Latin and Old Syriac versions than was formerly the case.

The Versions of the New Testament.—The New Testament was translated at a very early date—not later than the 2d century—into Latin for the North African Christians and into Syriac for the Christians of the East. Many of the Old Latin MSS. still survive, and are of great use to scholars in textual criticism. At the beginning of the 5th century a revised Latin version was constructed by Jerome, known as the Vulgate, and this is still the authorised version in use among Roman Catholics. Several MSS. of the Old Syriac version are in existence—one a very interesting palimpsest of the gospels discovered by Miss Lewis in the monastery of St Catherine on Mount Sinai in 1892, and now generally known as the Sinaitic Syriac. The Peshitta is a later revision—like the Vulgate in Latin—made from existing Old Syriac versions and current Greek MSS. in the time of Rabbulā, who was bishop of Edessa from 411 to 435. The New Testament was also translated into Coptic for the use of native Egyptian Christians. Two forms of this version remain, known as the Bohairic and the Sahidic respectively. It was largely due to the influence of these versions that Christianity became a permanent institution in Egypt in the shape of the Coptic Church. It is a striking fact that nothing remains of the splendid North African Church which, under the leadership of Cyprian and Augustine, won such renown and exercised such a mighty influence in the early centuries. Not a trace is to be found of any remnant of primitive Christianity in Algiers or Tripoli, while in Egypt the Coptic Church still survives as a relic of ancient Egyptian Christianity. The explanation is that the New Testament was translated into the native dialects of Egypt, but not into the tongue of the Berbers. The survival of the Coptic Church in Egypt, and the absence of any similar institution in the other regions of North Africa, is a valuable testimony to the power and influence of these translations of the New Testament. The Gothic version of the New Testament was made by Bishop Ulfilas in the 4th century, and the Armenian in the beginning of the 5th. The date of the Ethiopic version is not so clear, but it was probably made somewhere about

the year 500. Thus we see that within five hundred years the New Testament was translated into every language of importance in the civilised world.

Modern Criticism and the New Testament.—The specific treatment of the history of modern New Testament criticism will be found in the article on Biblical Criticism (see also GOSPELS), but there are some points which cannot be passed over here. We need not refer to the attack of Strauss upon the miraculous elements in the gospel, or the Tübingen theory of the origin and development of the literature of the New Testament. Both these forms of attack are out of date to-day. Modern scholarship is interested mainly in three problems: (1) the essential element in the teaching of Jesus; (2) the historical value of the gospel narrative; (3) the value of the theology of the epistles. Of course there are innumerable other questions in debate, but these are mostly concerned with the date and authorship of the different books. The general trend of opinion among scholars, for instance, is to deny the Johannine authorship of the Fourth Gospel, without disputing the fact that it owes much to his teaching and influence. The authorship of the Pastoral Epistles is still a matter of question, though the majority of modern authorities think that the difficulties in the way of accepting the Pauline authorship are insuperable. But such problems as these have now assumed a secondary interest in view of the larger and more vital issues that have been raised.

The Essential Point in the Teaching of Jesus.—Roughly speaking, there are two schools of thought: (1) the ethical; (2) the apocalyptic. (1) The ethical school—which perhaps finds its best expression in Harnack's *What is Christianity?*—maintains that Jesus was essentially a moral and religious teacher. His mission was to give the world a new ideal of God and man and duty. The Sermon on the Mount constitutes the heart and core of his revelation. The apocalyptic elements in his teaching are of secondary importance, and may be ignored. (2) The apocalyptic school, on the other hand, goes to the opposite extreme. It lays all the stress on those elements in the teaching of Jesus which speak of his speedy return to found the kingdom of God. The ablest exponents of this view are Johannes Weiss and Schweitzer, whose book, *The Quest for the Historical Jesus*, is quite revolutionary in its interpretation of the teaching of Jesus. According to the views of Weiss and Schweitzer, the ethical elements in the gospels are of secondary importance. Jesus never intended to draw up an absolute ethic, but only to lay down for his followers an 'interim-ethic,' which was to be valid only to the Parousia. The apocalyptic school have, undoubtedly, rendered great service by calling attention to a neglected element in the teaching of Jesus, but they have gone to too great an extreme in assuming that this aspect dominated the whole of his outlook. Jesus cannot be reduced to a mere ethical teacher, but, on the other hand, he cannot be regarded as a mere apocalypticist. Both aspects are obviously present in the gospels, and both must be included in any interpretation of the teaching of Jesus which has any real claims to be regarded as adequate.

The Historical Value of the Gospels.—Within recent years the historicity of the gospel narrative has been severely attacked by an extreme school of German critics headed by Drews and Kalthoff, who have tried to maintain that the gospel story is a pure romance, and that no such person as Jesus ever existed. 'The figure of Jesus,' they urge, 'is a creation of the imagination, and is derived chiefly from the atmosphere of the age.' Such a theory represents a mere delirium of criticism, for (1) it is inconceivable to suppose that

the portrait of Jesus in the gospels is the fortuitous concurrence of the atoms of theology and philosophy that happened to be in existence at the time. Points of affinity and resemblance, of course, there are bound to be between elements in the teaching of Jesus and elements in the religious life and thought of the age, but there is nothing to suggest that the picture of Jesus as a whole could have been evolved out of the *Zeitgeist*. (2) Our evidence for the reality of Jesus is stronger than is usually the case when we are dealing with historical personages in ancient history. It is stronger, for instance, than the evidence for Plato, and much stronger than the evidence for Apollonius of Tyana, though both these men are taken for granted by the critics who challenge the truth of the gospel narrative. (3) Even if we ignore the gospels, the evidence for Jesus in the epistles and in the history of early Christianity is simply overwhelming. But though we may dismiss this view as altogether chimerical, it does not follow that we are entitled to go to the opposite extreme and accept every statement in the gospels as historical fact without further examination. We must apply to the gospel narrative the ordinary canons of historical research. We must weigh and test the gospel narrative in the scales which the ordinary historian uses in order that we may discover its validity. We must carefully compare the documents, and arrange them in chronological order, and distinguish between the different strata of evidence. We must make allowance for the personal equation of the historian, and the influence of the time-spirit upon him. We must remember, for instance, that the Fourth Gospel is much later than the other three, and therefore likely to be less reliable, and that those parts of the Synoptics which embody more ancient sources take us back nearer to the events than the other elements, which are probably the writer's own contribution to the subject. We must remember, too, that the Fourth Gospel is obviously written with an apologetic purpose 'to prove that Jesus is the Christ, the son of God,' and that this purpose must have inevitably coloured the writer's treatment of his material. The whole investigation is very intricate and complex, and has not so far been carried through to its final issue. But we need have no hesitation in affirming that when this examination has been scientifically made, it will only serve to prove that the picture of Jesus in the gospels is substantially true.

The Value of the Theology of the Epistles.—Another point which is being challenged to-day is the validity of the theological statements of the epistles. Does the theology of St Paul, for instance, hold good for modern thought? One of the most remarkable advances in New Testament study in recent times is the use and application of what is known as 'the historico-critical method.' The historico-critical method lays down as its fundamental principle the proposition that we are bound to take into consideration the influence of the atmosphere of the time in estimating the value of the statements which we find in the New Testament books. We know, for instance, that St Paul was a Pharisee before he became a Christian. The mind which he brought to the examination of the Christian facts could not, therefore, have been a *tabula rasa*, but must necessarily have been stored and furnished with Jewish preconceptions and ideas. The doctrines of predestination, original sin, atonement, the resurrection of the body, have all their counterparts in current Jewish theology. Even the very categories which the apostle uses in his interpretation of Christ were in many cases borrowed from Jewish thought. We must remember, too, that Paul wrote for the 1st century, and that his object was to deal with the particular

problems and questions of the hour (if he had been writing to-day his statements would have assumed a very different form). Why should the 20th century be in bondage to 1st-century ideas? Would it not be an advantage if the Church were to free itself from the tyranny of Pauline thought? These arguments are sound enough when they are not carried to too great lengths. It is clear that we have to use the principles of the historico-critical method and make allowance for 1st-century influences and ideas upon the mind of Paul. There are obviously some things in the epistles that are merely of local and temporary interest. But when we are told that it is necessary to abandon Paulinism as a whole and rid ourselves of its influence, it is clear that the theory has overreached itself. Paulinism could not have exercised such a permanent and abiding influence on the Church if it had been merely the product of 1st-century ideas. The task of modern scholarship is to distinguish between the transitory and the permanent elements in Paulinism, to sift out the chaff of 1st-century ideas that the pure wheat of eternal truth may be made manifest. In order to do this satisfactorily we must find some scientific criteria, and fortunately there are certain criteria which enable us to fulfil the task with precision and conviction. We have to ask four questions. (1) What elements in the epistles are in accord with the teaching of Jesus? Agreement with the teaching of Jesus is sufficient to establish the validity of any doctrine. (2) What elements have been derived from personal religious experience? It is clear that truths which are the outcome of personal experience are more valid than statements which merely reproduce the current conceptions of the age. We must be on our guard, however. A religious experience is one thing, the interpretation of that experience something very different. In order to guard ourselves we are bound, therefore, to ask a third question. (3) How far have these truths been vindicated in general Christian experience? A truth is not merely true for one: it is true for all. In as far as the main ideas of Paulinism are valid, they will form an element in the universal experience of the Church. Then there is a fourth criterion which is very valuable for the purposes of testing values. (4) What elements in the theology of the epistles have been found to work in history? Christianity has been in existence for nearly two thousand years. The various phases and aspects of its teaching have been tested time after time. If the epistles of St Paul had been a mere *farrago* of 1st-century ideas, they would have gone out of date long ago. One of the strongest arguments for the permanent validity of the main elements in the Pauline theology is the undeniable truth of the assertion of Harnack, 'Whenever Paulinism has entered into history it has always created a ferment.' Paulinism has 'worked' throughout the centuries, and it is this fact that justifies its claim upon us to-day. Paulinism, after all, in its essential features is the transcript of a great religious experience, an experience that has become classic in its importance and value.

The Eternal Value of the New Testament.—The value of the New Testament lies not so much in its history, or even in its theology, as in the appeal which it makes to the heart and conscience of mankind. What Robertson Smith has said about the Bible as a whole especially applies to the New Testament. 'If I am asked why I receive Scripture as the word of God and as the only perfect rule of faith and life, I answer with all the Fathers of the Protestant Church, Because the Bible is the only record of the redeeming love of God; because in the Bible alone I find God drawing near to man in Christ Jesus, and declaring to us in him his

will for our salvation. And this record I know to be true by the witness of his spirit in my heart, whereby I am assured that none other than God himself is able to speak such words to my soul.' Criticism may alter our views about the authorship and dates of the different books, it may raise questions about this particular statement or that, it may analyse the influences which have shaped and coloured the human record, but it cannot touch what after all is the very centre and soul of the New Testament, the revelation of the grace of God in the Incarnation and redeeming work of Jesus Christ. The words of Coleridge will always be true, 'The Bible finds us at greater depths of our being than any other book.' We have long since abandoned the verbal theory of inspiration. We no longer think of the Bible as having been 'divinely ventriloquised through human masks.' We are bound to recognise to the full the free play of human activity in the composition of the different books. The authors were not mere automata of the spirit. Their personalities were never overridden by the influx of the divine afflatus. But the Bible could never have been the book it is, it could never have possessed its universal appeal, it could never have left such an impress upon the history of the world, unless its writers had in a unique degree been imbued with the divine spirit and inspired by God. We may not to-day make a theory of inspiration our starting-point, but some doctrine of inspiration is the goal to which our study of the Bible inevitably leads us. The supremacy of the Bible over all other forms of literature is so remarkable that some explanation is needed to account for it. And the measure of the difference between the Bible and other books is the measure of its inspiration. In other words, though we cannot say to-day 'The Bible is inspired, and therefore it is supreme among books,' we do say, and are bound to say, 'Because the Bible is supreme among books it must be inspired.'

Some account of the older translations will be found in the article BIBLE (sections headed *The Language and Text of the Old Testament*, and *The Versions of the New Testament*). See also BIBLICAL CRITICISM, SEPTUAGINT, TARGUM, VULGATE. In modern times versions have appeared in almost all spoken languages.

English Translations.—Partial translations and paraphrases into Old English are still extant. The first complete version in English was that of Wyclif about 1382, from the Vulgate. Of this, however, the gospels alone can be certainly identified as the work of Wyclif himself, and this portion was done as early as 1360. The Old Testament and apocryphal books were translated principally by Nicolas de Hereford. A later complete version of it was finished by Wyclif's friend, John Purvey, about 1388. The Scottish New Testament, printed by the Scottish Text Society, was adapted from Purvey for the use of Lollards in Kyle. Printing was introduced into England by Caxton in 1477, and translations and summaries of parts of Scripture appeared in various works from his press. The New Testament of William Tyndale was issued at Worms (1525); later editions, 1534–35. Tyndale also translated the Pentateuch, and some other parts of the Bible. The first complete printed English Bible was that of Miles Coverdale (1535). Coverdale's Bible is based upon the Swiss-German version (Zurich, 1524–29), with the use of Luther, the Vulgate, and Tyndale. Matthew's Bible (1537) is composite: the New Testament is Tyndale's 1535; the Pentateuch is also Tyndale; while of the rest, part is Coverdale, and part probably from Tyndale's MSS. The so-called Great Bible, a revision of Matthew's, was undertaken under the auspices of Cromwell, Earl of Essex; the printing, being interrupted in Paris, was completed in London (1539). In 1557 the English exiles who had found refuge in Geneva during the reign of Mary produced a version of the New Testament, with preface by Calvin, and in 1560 the whole Bible. This is known as the Geneva Bible, sometimes popularly as the 'Breeches Bible,' from the rendering, Gen. iii. 7. The

version was provided with racy notes, which made it a favourite with the common people (1st Eng. ed. 1576). Meantime a new version had been in preparation under the influence of Archbishop Parker. Separate portions were allotted to different scholars, chiefly of the Episcopal Church, and the whole was then revised by Parker and other learned divines. This version (1568) goes by the name of the Bishops' Bible, vulgarly the 'Treacle Bible,' from the rendering of Jer. viii. 22, 'Is there no treacle in Giliad?' In 1582 a New Testament was issued by the English Catholic College at Rheims, and the Old Testament in 1609 at Douai. In 1604 James appointed a conference at Hampton Court for determining of things said to be 'amiss in the church.' The suggestion of a new translation, made by Rainolds, was taken up by the king, and six committees were appointed to execute the work. Two of these sat at Westminster, two at Cambridge, and two at Oxford, their work being revised by a general committee. The version appeared in 1611. The 'Revised Version' was due to the suggestion of the Convocation of Canterbury. Two companies of translators were appointed, one for the Old Testament, and the other for the New. They began to sit at Westminster in 1870; the New Testament was issued in 1881, the Old in 1885, and the Apocrypha in 1895. After the work had been begun, a number of American scholars were added, and all points of ultimate difference of opinion between the English and American revisers were appended to the versions issued. The 'Westminster Version of the Sacred Scriptures' with notes began to appear in 1913 under the general editorship of Fathers Lattey and Keating. The monopoly of printing the authorised version of the Bible belongs to the crown, by whom it is granted to certain patentees. See BOOK-TRADE.

German and other Translations.—Early in the middle ages translations of portions of the Bible were rendered into many of the western languages, but these were mostly explanatory paraphrases or versions of the Bible narratives in metre rather than translations proper. Otfrid's *Krist* is a rhymed harmony of the gospels in High German, and the *Heliant* in Low German alliterative verse. The Abbot of St Gall's version of the Psalms (980) and the gospel harmony of 'Tatian,' from the Latin of Victor of Capua, follow next; and to these succeed numerous German versions of the histories and other books. Complete German versions from the Vulgate existed as early as the first half of the 14th century. It is claimed that there were seventeen or eighteen such versions prior to Luther's, and of these five were previous to 1477. Already in the end of the 12th century Provençal translations were in the hands of the Albigenses, and the demand for the Bible in the vulgar tongue spread widely in spite of the prohibition of the Church. In Spain, Alfonso X. of Castile is said to have caused the Old Testament to be translated. Another version done in 1422–30 by Moses Arragel was printed in 1923. The history of the earliest versions in Polish, Italian, and Hungarian is hopelessly obscure. Printing gave an enormous impetus to the translation and production of the Scriptures. A Spanish version by Borrell was published at Valencia in 1478, an Italian by the Benedictine Malherbi at Venice in 1471, a French at Paris in 1487, a Bohemian at Prague in 1488, and a Dutch as early as 1477. Luther's translation of the whole Bible was finished in 1534, but the New Testament had been issued as early as 1522. It was by no means, as has been seen, the earliest translation into a German tongue, but it was the first that reached the whole people, and it marked an epoch in the history of High German corresponding to that made in English by the authorised version of 1611. It

was quickly translated into Platt-Deutsch, Danish, Swedish, Dutch, and Icelandic. A revision was commenced in 1863, and not completed till 1882. The Bible of Holland is that authorised by the Synod of Dort in 1637; of Sweden, the official version, prepared by a company of scholars since 1774. The Danish is the work of Resenius (1607), revised by Svaning (1647); the Swiss, an entirely new version prepared in 1772 by Hottinger and others, on the basis of the 1665 version. French versions were made by Lefèvre d'Étaples (Faber Stapulensis) in 1523-28, and Olivetan, a cousin of Calvin's (1535-45). The latter as revised by Calvin in 1551, and later by Beza, became the official text of the French Reformed Church. The translations of Osterwald of 1714 and 1744 are also popular in spite of their conspicuous errors. Another edition still is in use, that prepared in 1588 by the *Vénérable Compagnie* under the direction of Bertram, on the basis of Calvin's, which was subjected to some revision in 1805 and again in 1835. There are many versions of the Old and New Testaments by individual scholars, such as the Latin Testament of Beza, but these belong rather to the history of exegesis. Translations of the Bible have now been made into almost all the languages of the world. See further articles on the various languages; also BIBLE SOCIETY, CYRIL.

Bible Society, an association having for its object the diffusion of the sacred Scriptures. One was founded in 1710 at Halle. An association was formed in England in 1780 for the distribution of Bibles among soldiers and sailors, and afterwards took the name of the Naval and Military Bible Society.—The British and Foreign Bible Society, the parent of a multitude of similar institutions, was established in 1804. It was able to expend only £691 in the first year of its existence, but its annual income gradually increased. Auxiliary and branch societies and dependent associations rapidly sprang up in all parts of Britain and in the colonies. It has printed and distributed over 500 translations of the Bible—in many cases complete, in others only the New Testament, in some only particular books; and it issues annually above four million copies of the Bible or parts of it.—The Edinburgh Bible Society was from 1826 an entirely separate society, till 1861, when the leading Scottish societies amalgamated to form the National Bible Society of Scotland.—The American Bible Society was founded at New York in 1816, and issues annually about 1,500,000 copies.—Of the numerous Bible Societies of Germany, the most important is the Prussian Central Bible Society in Berlin, founded in 1814. See the *History* of the British and Foreign Bible Society by William Canton (4 vols.), the shorter *Story* by the same author (1904), and the *Centennial History of the American Bible Society*, by H. O. Dwight (1918).

Bibla Pauperum ('Bible of the Poor') was a sort of picture-book of the middle ages, giving, on from thirty-four to fifty leaves, the leading events of the Old and New Testaments, each picture being accompanied by an illustrative text or sentence in Latin. Each picture with its text was at first engraved on one wood block. But early in the 16th century the method fell gradually into disuse, and was superseded by ordinary printing from types. See BOOK, PRINTING, WOOD-ENGRAVING.

Biblical Criticism. The term Biblical criticism might properly embrace all types of criticism as applied to Scripture. In practice, however, it does not include literary criticism in the sense of æsthetic valuation of the Bible as literature. Literary criticism is indeed the element most prominent

in it, but as equivalent to what is commonly known as higher criticism. But the term ought not to be restricted to this, since it includes lower criticism and historical criticism. Our first duty, then, is to discriminate between these different departments of our province. This cannot be effected with precision, for the boundaries fluctuate, and several problems belong to more than one department. Nor, while we separate the spheres of investigation for practical convenience, should we ever forget that the results in one often affect the conclusions reached in another. Textual, or, as it is also called, formal or lower, criticism seeks to restore, so far as possible, the document under investigation to the form in which it left the author's hand. When this has been done we pass on to the investigation of such problems as the date, the authorship, and the detection and reconstruction of the sources employed in its composition. This is the province of higher or material criticism. It is called higher to distinguish it from the lower criticism. In view of widespread misapprehension it may be explained that the epithet implies no claim to superiority, nor yet is it specialised to designate novel and revolutionary as opposed to traditional views. Nor, again, does the term lower criticism imply any agreement on problems of authorship and structure with the views commonly entertained. The distinction is one of subject matter, and not of results. The scholar who seeks to solve the problem of authorship by scientific scholarship employed with scientific method is practising higher criticism as much when he reaches a conservative as when he reaches a negative conclusion. When the text of the document has been fixed and its literary history has been traced, we pass from lower and higher to historical criticism. Here we have to test first the qualifications of the author for writing a truthful narrative, and then we can advance to the scrutiny of the narrative itself. It may be added that some authorities use the term higher criticism to cover what is best kept under the heading of historical criticism.

This rough delimitation will become more precise as we proceed to the exposition of method and results. But before this is undertaken, it may be well to give a fuller application to the caution already given against undue isolation. Just as the investigation of one province of criticism inevitably reacts on that of the others, so Biblical criticism must constantly take into account other branches of Biblical science, notably exegesis and theology. The true interpretation of the text may often have a decisive voice in determining which of two variant readings is to be accepted, while a false interpretation may easily vitiate a critical conclusion based on the evidence of the passage. And, conversely, an interpretation of a passage, possible in itself, may be excluded by the impossibility that the author should have meant it, or by the fact that at the date to which criticism assigns it, it would have been an anachronism. Similarly with Biblical theology. That Paul cannot have written the Epistle to the Hebrews, though abundantly demonstrated by other lines of argument, could be inferred with certainty from a comparison of its theology with Paulinism. Nevertheless, while the student must never forget the solidarity of all the different provinces of his subject, he should seek, as far as possible, to investigate each by its own methods and within its own limits, without calling in aid from its neighbours.

Textual criticism has a very restricted sphere of operation in modern literature. But before the invention of printing every copy had to be written out independently, and the chances of scribal error were naturally increased with every fresh copy, since the scribe was likely to reproduce all the errors of his copy and add new ones of his own.

Accordingly in any ancient work, since we are dependent on manuscript copies, most of them removed from the autographs by many stages of transcription, textual criticism has an important part to play. This is specially the case with literature that has passed through the hands of so many scribes as the Scriptures. There is, however, a notable difference between the Old and the New Testament. The Hebrew Bible has been transmitted to us in a standard text from which the manuscripts present very little substantial divergence. On the other hand, the manuscripts of the Greek New Testament differ very widely from each other, and the number of various readings is enormous. It would be a mistake to infer that the text of the Old Testament has been better preserved than that of the New. The absence of variants is no cause for congratulation; it is a misfortune to be deplored. For it is not due to the minute accuracy with which the text has been copied. The elaborate precautions taken against copyists' errors do not date back beyond the Christian era. And that our present Hebrew text is corrupt is clear from many indications. At times it cannot be translated without grammatical violence; in other cases the versions, and notably the Septuagint, have preserved a different and obviously a better text; in some cases we have two versions of the same matter with variants, due plainly to textual corruption; and finally, even where none of these grounds for suspicion are present, close examination may suggest the presence of textual error, which can be easily cured by a slight conjectural emendation. The absence of Hebrew variants of moment can only mean that a standard text was formed and manuscripts differing from it were suppressed. Hence were it not for the versions we should be left for the most part without variant readings. In the New Testament, on the contrary, the immense number of variants gives the critic abundant material on which to work, and confidence that the original reading is very rarely likely to have been entirely lost. It is his object to reconstruct a text corresponding as nearly as possible to the autograph. The process may be best seen by reference to the New Testament. Here it is necessary to leave the examination of individual passages until some valuation of the manuscripts and versions has been accomplished and the general history of the textual tradition has been traced. The manuscripts may be examined one by one to determine whether on a broad view they seem to preserve a good text—that is, whether, in the case of variants, they generally approve themselves as preserving readings marked by intrinsic excellence. This involves, of course, some preliminary judgment on many individual passages. But where it is carried through, in a large number of instances a fairly reliable opinion may be reached on the general character of the manuscript. Since, however, an examination of the textual apparatus quickly shows that manuscripts tend to fall into groups, the method applied to the individual manuscript may be extended to groups of manuscripts. Judgments of this sort, however, depend on the impression formed by the critic as to what is a good reading, and there is accordingly an element of subjectivity in it. The genealogical method has a more objective character. It is possible to construct a genealogical tree, which shall exhibit the relations of the manuscripts, separate the different lines of transmission, determine which types of text are old, which more recent and due to revision, and from readings shared by manuscripts on different lines of descent reconstruct the text of the common ancestor. We may thus reach a more objective valuation of manuscripts and groups of manuscripts. In many cases the true reading may be at once decided by reference to the authorities by which it is supported. What

applies to manuscripts applies also to versions and quotations, the necessary allowances being made, and due precautions being taken. Yet internal evidence must not be lost sight of, and in a multitude of instances it must give the decisive vote. The causes of corruption must be carefully studied. Some errors arise from defective hearing where the scribe writes from dictation, especially if there is defect in pronunciation or the pen cannot keep pace with the utterance. Others are due to misreading or to the occurrence of the same word twice, the scribe writing to one and resuming at the other, and thus either writing a passage twice over (dittography) or omitting the intervening words. Or abbreviations may be misinterpreted. Wandering thoughts may introduce something quite irrelevant, or the influence of similar passages may lead to assimilation. What is doctrinally objectionable may be modified or suppressed. Annotations on the margin may by the next copyist be woven into the text. Passages accidentally omitted may, when the mistake is discovered, be written in the margin and then introduced into the text at the wrong place. Possibly they may be written between two columns and then introduced into the wrong one. Or again, the writing may be blurred, the ink have faded, or the surface been rubbed, and illegibilities thus created mistakenly corrected. The critic must be on the watch for the operation of these and other causes. And there are certain principles by which we must be guided. That reading is most likely to be right by the assumption of whose originality the other variants can be best explained. The more difficult reading is generally to be preferred, the tendency of scribes being to simplify their text rather than to make it more obscure. Generally the scribe does not improve the text; he frequently makes it smoother and superficially more plausible, but on reflection his text is found to be thinner and less satisfactory. It is not possible in our space to follow the history of textual criticism, and the present position has been explained in the article **BIBLE**.

When the text has been settled, the student of a document has to inquire into its age, authorship, and literary history. These questions fall within the province of the higher criticism. He will search for allusions which will fix the date of the work in its present form, or at least a date before which it cannot have been written. The date after which it cannot have been written may also be determined either by internal phenomena, inconsistent with later origin, or by information as to its existence or evidence of its influence. These limits may often be fairly wide, but it may be possible by minuter and more extended study to make them much narrower. Authorship may sometimes be settled by the direct affirmation of the work itself, which is to be accepted, unless there is cogent reason to the contrary; or it may be settled by trustworthy tradition. Often these independent lines of evidence will afford mutual corroboration. In many cases, however, neither is available, and we have to recognise anonymity even where the date can be determined with some precision. But criticism is not then at the end of its task, as it would commonly be in the case of a modern work. For many documents have come down to us from antiquity which are composite in structure. They are not the creation of a single author bearing throughout the stamp of a single mind, but they have been formed by the combination of two or more documents. The critic must accordingly now examine his text to see whether it exhibits signs of composite authorship. These may lie on the surface in discrepancies, inconsistencies in standpoint, glaring divergences in style and vocabulary, or they may be brought to light only by more prolonged

and minute investigations. Something will depend on the skill with which the editor has blended his sources, eliminated inconsistencies, and contrived to impart an appearance of unity to the whole. When the critic is satisfied that sources have been incorporated, his next task is to disentangle these and determine their age. This task may conceivably prove impossible; but the fact that analysis is impracticable constitutes no valid disproof that the document is composite. Generally, however, analysis may be accomplished, though naturally with varying success. Scrutiny may disclose the presence of doublets—that is, double versions of the same event. If there are a number of these they may be examined for characteristic features. These features may be found in a whole series of stories, which may then be plausibly assigned to the same author, if other features do not forbid this. On this basis it is possible to extend the investigation to other portions, and thus gradually to sort out the homogeneous sections. The correctness of the analysis may be tested by the internal consistency of the sources thus reconstructed, by the possession of a common vocabulary, style, and point of view. Nevertheless, the analysis may have been correctly effected, and yet internal inconsistencies remain. This may be compatible with unity of authorship, since writers do sometimes contradict themselves; but it may be an indication that the analysis has not gone deep enough, and that states exist within the source challenging the critic to a still keener analysis. Yet the warning is by no means unnecessary that criticism may easily pass into hyper-criticism, that the microscope may be trusted too much, and minute points may be unduly pressed. But the scorn often heaped upon the finer analysis is not wholly justified. On this subject the writer may perhaps quote what he has said elsewhere. 'On the one hand, the excesses of analysis should not be used to discredit the analytic method altogether; and the critics constantly point out that their attempts at minuter discrimination of sources are quite tentative, and that an element of uncertainty must necessarily hang over them. On the other hand, it is clear that growing familiarity with the documents may sharpen the sense of the investigator for finer and finer analysis. The clues which he follows to unravel his tangled skein seem altogether too intangible to people whose fingers are all thumbs' (*The Bible: its Origin, its Significance, and its Abiding Worth*, pp. 167, 168).

The disentanglement of sources, the determination of their limits, the fixing of their dates, are important rather as means to an end than as the end itself. Biblical history and theology are alike dependent upon Biblical criticism. Only when we have rightly dated our sources and placed them in their chronological order can we reconstruct the development of Israel's religion, or trace the growth of early Christianity. And similarly, if we would discover the actual course of events, we must have carried through the criticism of the sources before we proceed to consider the stories which they tell. The processes of historical criticism cannot be discussed here in detail, and the statement must be limited to a few points. Great stress is naturally laid on contemporary documents, or, where these are not available, on such sources as lie nearest to the events. Of course, even contemporary documents cannot be used without caution, for we should have to consider how far the writer was in a position to know the facts, or competent to understand and explain them. We must allow for the bias which may have deflected his judgment and distorted his representation. If we have inconsistent accounts before us, our preference will be determined, not simply by chronological priority, but by the opinion we have formed on the general

qualifications of the two authors for giving us accurate history. But preference for one does not imply that it is to be implicitly followed, or that the other is to be summarily set aside. The source which is better, on the whole, may contain unhistorical elements, while the inferior tradition may retain some genuine reminiscences which its rival has lost. But, perhaps, even more important is the fact that two traditions place us in a much more favourable position than one for reaching the facts. It is the critic's object not simply to get behind his documents to their sources, but to get behind the sources to a still earlier stage of the tradition. Now the existence of two traditions enables him to do this, especially if they are divergent and independent, because he can gradually feel his way back to the source of both by discovering that form of the story from which both can be explained. Yet even when this has been discovered there remains the problem of its historicity, and this has to be determined by a variety of considerations. Among these may be mentioned the nearness of our hypothetical source to the events recorded; the internal consistency of the story; the possibility of fitting it into its general historical context; and its intrinsic probability. We have to consider whether there are motives which were likely to have led to its invention or its distortion. In many instances it is easier to reach negative than positive results; to prove that a book was not written at a given time, or by a given man, than to say when or by whom it was written; to prove that one alleged event did not happen than to prove that another did. Yet even when a negative conclusion has been reached, it does not follow that narratives set aside as unhistorical are therefore of no value. They may be precious in various ways as illustrating the causes which give rise to such stories, as throwing light on the ideals, the tendencies, and conditions of the age in which they originate, and for their intrinsic value, if not as history, yet as poetry or parable.

The argument from silence must be used with great caution. It is proverbially dangerous, yet by no means without value, especially as a confirmation of conclusions reached on positive grounds. There are cases where it is almost conclusive, though we are warned to be careful by the fact that writers are occasionally silent where we should have anticipated that had they known they must have spoken, where, nevertheless, their knowledge is beyond all question. Special importance will be attached by the critic to converging lines of independent evidence. Even comparatively slight arguments, all pointing in one direction and all mutually independent, may, in combination, amount to demonstration, whereas a strong argument standing by itself may fall short of it. A case needs to be scrutinised with special care when it rests on a chain of reasons, for here the argument grows weaker at every step when the inference falls short of certainty, and the chain is no stronger than its weakest link. Again, where one conclusion is only slightly more probable than another it is precarious to build upon it. A very small weight of evidence may readily change the balance of probability. Finally, in view of widespread impressions to the contrary, it may be emphasised that the aim of criticism is not primarily destructive. Naturally much may have to be pulled down, but it is to clear the site for a worthier erection. Nor is criticism as such hostile to the supernatural, though it is obvious that, at least in the New Testament, theology or metaphysics may ultimately control results. Only it is well that critical processes should, as far as possible, be carried along their own lines to at least provisional results, and if theological or metaphysical considerations are

introduced this should not be done surreptitiously. So far as the Old Testament is concerned, the vital problems are unaffected by the question of miracles.

It is not possible to sketch the history of Biblical criticism in anything but the barest outlines. It is not entirely a modern development, but the keenness, the thoroughness, the scientific method employed made the criticism of the 19th century to all intents and purposes a wholly new thing. So far as the Old Testament is concerned, the most important debate has centred about the Pentateuch. Indications of post-Mosaic origin were pointed out by Hobbes, Spinoza, and others; but it was in 1753 that Astruc hit on the difference of the divine names in Genesis—Yahweh and Elohim—as providing a clue to analysis. He did not deny Mosaic authorship, but towards the close of the century Geddes, while recognising a considerable Mosaic element, maintained that the Pentateuch was not the work of Moses, but probably belonged to the reign of Solomon. He did not, however, accept the clue to analysis given by the divine names. De Wette (1806-7) gained a fixed point for future development in his identification of Deuteronomy with the Book of the Law discovered in the time of Josiah. In method, also, he effected a most important advance by the comparison he made between the description of institutions in the early historical books (Chronicles he regarded as largely destitute of historical value) and the corresponding laws in the Pentateuchal codes. So far as Elohistic source, a non-Elohistic source, and Deuteronomy had been distinguished. In 1853 Hupfeld, who had in this been anticipated by Ilgen (1798), completed the analysis on its main lines with the recognition of two Elohistic sources, one having closer affinities with the non-Elohistic source than with the other Elohistic document. Four main sources were thus recognised, now commonly known by the symbols J, E, D, P. The first two of these contain those elements which give the narratives their perennial charm; the last, on the contrary, the Priestly Document, contrasts strongly with them by its concentration on ecclesiastical institutions and ceremonial, its indifference to human interest, its curiously stereotyped and formal style. Literary analysis, however, had to be completed by the determination of date. The age of Deuteronomy had been roughly determined by De Wette as falling not so long before 621 B.C. It was commonly held that the Elohistic source was the earliest, and after Hupfeld's demonstration that two writers used Elohim as a proper name, P was regarded as the older, and E as the younger Elohist. The view that P was the earliest of the documents was dominant till towards the close of the 'seventies, not indeed without protest. Reuss, as early as 1833, had reached, by divination rather than close investigation, the view that the true order of the literature was not Law, Psalms, Prophets, but Prophets, Law, Psalms. In 1835 Vatke and George had both recognised the late date of the priestly legislation. This was important, not in result only, but in method. It involved a clear recognition of the fact that the history of religious institutions was the decisive element in the dating of the documents. Their work remained for long without effect, and thirty years elapsed before Graf published his case for the post-exilic dating of the priestly legislation. Meanwhile, the separation between P and E had been effected. Graf was himself so much under the spell of the dominant belief that the narrative sections of P were very ancient, that he made an unhappy attempt to divide the document, and while making the legislation later than the exile to place the narratives many centuries earlier. It was easy to prove that a document so homogeneous could not be

analysed on these lines; and Riehm, availing himself of Graf's ill-considered admission, argued that the antiquity of the legislation was guaranteed by the antiquity of the narratives, from which it could not be separated. Precisely the opposite influence might, however, be drawn, and Kuenen drew it. Inasmuch as the legislation was demonstrably late, the narratives, since they were inseparable from it, must also be late. The correction was accepted by Graf, who thus carried out his criticism to its logical issue; and so the Grafian theory, which places the Priestly Document after the exile, was stated in its correct form, and attention was concentrated on the real rather than a false issue. Kuenen did much by his *Religion of Israel*, and his brilliant articles in the *Theologisch Tijdschrift*, to commend the hypothesis; but Germany was solid against it till Duhm, in his *Theology of the Prophets*, expressed his adhesion, and contributed a valuable argument in its favour by his proof that the prophets did not presuppose the Law. It was in 1878, however, that the decisive victory was won by the publication of the first volume of Wellhausen's *History of Israel*, which bore in its later editions the title *Prolegomena to the History of Israel*. Since that time the theory has been far the most widely accepted by Old Testament critics. Nor, in spite of frequent assertions to the contrary, is it the case that either the composite character of the Pentateuch or its analysis into four main documents, or yet the view that P is the latest and subsequent to Ezekiel, is in danger of being dislodged from its present acceptance. On these results many mutually independent and mutually corroborating lines of evidence converge; and the more closely the documents are studied, the more the conviction is strengthened that the problem of the Pentateuch has, at least in the main, been correctly solved.

Naturally investigation has not been limited to the Pentateuch, but has extended to the whole of the Old Testament. Space will not permit any sketch of the critical development, nor more than the barest summary of results. Reference must be made to the article on Bible, and to those on the individual books. In the historical literature much has been done to disentangle older and later strata, and to trace the processes of editorial compilation and revision. In this way, even from works in their present form late, older sources of great historical value have been disengaged; while the later sources, and the editorial handling of the history, if less precious for our acquaintance with the periods of which they tell, are invaluable for the light they throw on the periods in which they were composed. The prophetic literature has also been submitted to a very keen analysis. The Book of Isaiah has naturally attracted the most attention. The recognition that chapters xl.-lxvi. are not the work of Isaiah, but later than the exile to Babylon in 586 B.C., was one of the earliest and most assured of critical results. That these chapters are not the work of a single author is now generally recognised, xl.-lv. being commonly assigned, with or without the four Servant Poems, to the second Isaiah; lvi.-lxvi. being composed after the return by one or more writers, for the most part in the 5th century B.C. The problems of the earlier part of the book are, however, much more intricate. It had long been recognised that several sections must be later than the time of Isaiah: xiii. 1-xiv. 23, xxi. 1-10, xxiv.-xxvii., xxxiv., xxxv., being for long admitted to be non-Isaianic. But considerable additions had been made to this list by several scholars before the criticism of the book entered on a new era with the publication of Duhm's Commentary in 1892. He detached from Isaiah not a little that had hitherto been left to him, notably happy endings, and in contradiction to accepted

views as to the date at which the canon of the prophets was closed, assigned much to the Maccabæan period. His criticism has had great influence, but his position has not in some of its most characteristic features met with wide acceptance. Jeremiah, which even Graf regarded as largely authentic, has been similarly treated, much being now regarded as due to glossators or editors. Here, again, Duhm's revolutionary conclusions are regarded by most critics as unduly extreme, the more moderate criticism of Cornill commending itself as safer.

On the other prophets there is no space to linger, nor can we speak in any detail of the remaining books. It must suffice to summarise with the utmost brevity the generally accepted results. Job is now commonly regarded as belonging to the former part of the post-exilic period, the speeches of Elihu, the poem on Wisdom, the descriptions of Behemoth and Leviathan, and possibly, though in the present writer's judgment not probably, the speeches of Yahweh being later insertions. The Psalter is in the main post-exilic; some pre-exilic compositions may be preserved, perhaps even a small number of Davidic Psalms. Some scholars tend even to recognise a large number of Maccabæan and even Hasmonean Psalms. As little would be attributed to Solomon as to David, and that only in Proverbs, which, in the main, is post-exilic. The Song of Songs probably belongs to the Greek period, while Ecclesiastes is scarcely earlier than about 200 B.C. Daniel is Maccabæan, Esther probably late Maccabæan. For a detailed discussion of these problems reference must be made to the relevant articles.

New Testament criticism in its modern scientific form begins with F. C. Baur. Not that important issues had not previously been raised, or notable contributions made to their solution, but it is the imperishable merit of Baur to have lifted the subject out of the atomistic treatment formerly given to it, to have treated individual problems in close connection with each other, and as part of a great connected whole, and to have kept the development of the literature in the most intimate association with the movement of the history and the development of theology. The Tübingen theory, with which his name will be for ever linked, was that the development of the early church started from a conflict of opposite tendencies, Jewish Christianity and Paulinism, and was marked by growing approximation of the parties until they merged in the Catholic Church of the 2d century. Each piece of literature in the New Testament was dated according to the stage of the struggle which the Tübingen critics thought to be reflected in it. Only four Epistles were left to Paul: Corinthians, Galatians, Romans i.-xiv.; the Apocalypse to the Apostle John. As an authentic source for the teaching of Jesus, Matthew was the most trustworthy. Luke was toned down in the interests of Paulinism. Mark, as the most neutral, stood nearest of the Synoptists to Catholicism. The fourth Gospel originated far down in the 2d century; it reflected the union which had been reached in the Church. The Acts of the Apostles was also written from the Catholic standpoint, and refashioned the history of the Apostolic Church, substituting for the sharp antagonism between Paul and the primitive apostles an edifying picture of harmony. The Tübingen position, maintained with massive learning, great critical resourcefulness, and superb skill, failed in spite of its wide acceptance to maintain its ground. Hilgenfeld retrenched it of some of its extravagances. Ritschl offered a new construction in its place. Many of the supports on which the school relied have been broken down; many of the detailed results have been abandoned. Literary criticism has been emancipated from the

dominion of a historical theory, and particularly in the case of the Gospels, has reached quite opposite results from Baur's. Thus Mark is almost by common consent now regarded as the earliest of the Synoptists, and the late dates for much of the literature have been set aside, most of it falling in the 1st century. Most of the Pauline epistles are recognised to be authentic. The principle of the development from primitive Christianity to Catholicism was much more complex than Baur realised. Criticism would now relegate the factor which he made all-dominant to a very subordinate position. Yet, when every deduction has been made, it remains true that Baur did much to set us our problems; he asked the right questions, although his answers no longer satisfy us, and his method remains our abiding possession.

Bibliography is sometimes understood to mean expert knowledge of book-production—the history of handwriting and typography, of printing and book-illustrating, paper-making, book-binding, book-selling, book-plates, the rarity and cost of rare works, &c. See **BOOK**, **BOOK-TRADE**, and the articles on the several subjects named. The list of works appended at the end of many of the articles in this work is, in another sense, a brief bibliography for the subject dealt with. In the wider sense, bibliography deals with comprehensive catalogues of books and their authors, essaying to give a conspectus of all the books in some great library; all the books in a language (English, French, &c.), or in a special period; all the books dealing with certain subjects, or a selection of the best of them. And there may obviously be bibliographies of bibliographies. In this sense, bibliography as a branch of learning was enormously indebted to Brunet's *Manuel* (5th ed. Paris, 1860-65) and Watt's *Bibliotheca Britannica* (1824). For Great Britain, standard works of reference are Lowndes, *Manual* (1834); Allibone, *Dict. of British and American Authors* (Phil. 1859-71, with continuations); Sampson Low's *English Catalogue of Books* (1833, continued to the present time); Sonnenschein's *Best Books* (3d ed. 1910); the general catalogue of the British Museum (1881 *et seq.*) and the 'subject index' of modern works added since 1880; *Book Prices Current*; and the *Publishers' Circular* (since 1838). For America there is the *American Catalogue and America's Book Prices Current*. For France, besides Brunet, there are Quérard and Lorenz; and for Germany, Heinsius, Kayser, Hinrichs, and others. Of bibliographies of bibliographies, Petzholdt's *Bibliotheca Bibliographica* is first, extended by Stein; and there is a valuable List of Bibliographical Works in the Reading-room of the British Museum.

Bibliomancy (Gr. *ta biblia*, 'the Bible,' and *manteia*, 'divination'), a mode of divination by opening the Bible haphazard, and observing the first passage which occurred, or by entering a place of worship and taking notice of the first words of the Bible heard after entering it. The application was often very fanciful, and depended rather upon the mere sound of the words than upon their proper signification or the scope of the passage. Prayer and fasting were sometimes used as a preparation for a mode of consulting the divine oracles. Bibliomancy was prohibited, under pain of excommunication, by the Council of Vannes, 465 A.D., and by the Councils of Agde and Orleans in the succeeding century. It continued, however, to prevail for many centuries thereafter, and is said to have been introduced into England at the Norman Conquest. Tennyson introduces it into *Enoch Arden*. It was essentially the same as the famous *Sortes Virgilianæ*, the only difference being in the book employed.

Bibliomania, the passion of the book-miser,

which impels to the gathering and hoarding of books without regard to their literary value or practical utility; or, in its nobler aspect, in Andrew Lang's phrase, the 'love of books for their own sake, for their paper, print, binding, and for their associations, as distinct from the love of literature.' The word in English is modern, having been introduced from France about 1750; but the thing must be in some form as ancient as the existence of printed or written documents. In this, as in other passions of the like kind, the freaks of individual fancy are endless: while one man disdains everything save the 'tallest' copy of a rare work in the finest condition, another takes pity on the dingiest waif of the back-street bookstall. Fashion, too, exercises a great influence on the form in which bibliomania displays itself: it is no longer the prevailing hobby to collect Elzevir and Foulis editions, but he is a special favourite of the gods who possesses a set of the parts of *Pickwick* in the original green paper covers, or of early Thackerays in their original yellow.

See Dibdin, *Bibliomania* (1811); Hill Burton, *The Book Hunter* (new ed. 1882); Percy Fitzgerald, *The Book Fancier* (1886); Andrew Lang, *Books and Bookmen* (1887); Gustave Brunet, *La Bibliomanie en 1883*; W. Roberts, *Rare Books* (1895); J. E. Hodgkin, *Rariora* (3 vols. 1902). See also BIBLIOGRAPHY; and for famous bindings, BOOKBINDING.

Bibra, BARON ERNST VON (1806-78), born in Franconia, wrote on chemistry, was the author of some fine tales, and published an account of his travels in Brazil, Peru, and Chili.

Bicarbonates. See CARBONIC ACID.

Bice (Ger. *Beis*, Ital. *Biadetto*), the name of two pigments of a blue and green colour respectively, known to artists from the earliest times—blue bice as *mountain blue*, *ongaro*, *azzurro di terra*, &c.; and green bice as *chrysocolle*, *Hungarian green*, *verde de Miniera*, *verde de Spagna*, *verdetto*, &c. These pigments consist of a natural clay mixed with yellow ochre, the blue and green colours being due to native carbonate of copper. Bice has not much body, but dries well with oil. There are several artificial varieties, which, however, are not so durable as the natural. Although a favourite with artists in the beginning of the 19th century, its use is dying out, so that it no longer appears in colour catalogues, its place being taken by 'Hooper's Green.'

Biceps ('double-headed'), an anatomical term applied to two muscles, the one belonging to the arm, the other to the leg, and distinguished from each other as the *biceps flexor cubiti* and the *biceps flexor cruris*. The former is the muscle which gives a full appearance to the front of the upper arm; the latter is situated on the back of the thigh, and is one of a group of three muscles known as the 'hamstrings.' See ARM.

Bicester, a market-town of Oxfordshire, 12 miles NNE. of Oxford, and seat of the county court-house. There are manufactures of rope, clothing, sacking, and pale ale, and several important fairs are annually held. The ruins of *Alia Castra*, or Alcester, lie $1\frac{1}{2}$ miles to the south-west, on the ancient Roman Akeman Street. The population of the urban district is 3000.

Bicêtre, a celebrated hospital, situated on a little eminence in the southern neighbourhood of Paris, and commanding one of the finest views of the city, the Seine, and the environs. Founded by Louis IX. as a Carthusian monastery, it was acquired in 1290 by John, Bishop of Winchester (hence the name Bicêtre), and in 1632 it was destroyed, because it had become a hiding-place of thieves. Afterwards, it was rebuilt by Louis XIII., and made a hospital for old soldiers. It was

for a long time used as a prison for criminals, but is now a hospital for indigent old men and for incurable lunatics.—Bicêtre is also the name of one of the sixteen detached forts that defend the approaches to the walls of Paris.

Bichat, MARIE FRANÇOIS XAVIER, an epoch-making anatomist and physiologist, was born in 1771 at Thorette, in the department of Jura. He studied chiefly in Paris under Desault, who adopted him as his son, and whose surgical works he edited. In 1797 he began giving lectures on anatomy, along with experimental physiology and surgery, and in 1800 was appointed physician to the Hôtel-Dieu. Worn out by his unremitting labours, he died of fever in his thirty-first year, July 22, 1802. He was the first to simplify anatomy and physiology by reducing the complex structures of the organs to the simple or elementary Tissues (q.v.) that enter into them in common. This he has done in his *Anatomie Générale* (2 vols. 1801). In his *Recherches Physiologiques sur la Vie et la Mort* (1800), he discusses all the functions of organic and animal life, and their mutual relations.

Bickerstaffe, ISAAC, popular play-writer, was born in Ireland about the year 1735, and at the age of eleven became page to Lord Chesterfield, the lord-lieutenant. He was afterwards an officer of marines, but was dismissed the service for some discreditable offence, and in 1772 had to flee the country on a capital charge. Nothing is certainly known regarding his after-life, but he is supposed to have died on the Continent in or soon after 1812. Of his numerous pieces, produced between 1766 and 1771, the best-known are: *The Maid of the Mill*, *The Padlock*, *He Would if He Could*, *Love in a Village*, *The Hypocrite*, and *The Captive*.—Under the nom de guerre of 'Isaac Bickerstaff,' Swift wrote works in 1708-9; and the same name was used by Steele in the *Tatler*.

Bickersteth, EDWARD, evangelical clergyman, was born at Kirkby Lonsdale, Westmoreland, in 1786, and after fifteen years in the General Post-office and in a solicitor's office, was in 1815 admitted to orders, and sent the next year by the Church Missionary Society to reorganise their mission stations in Africa. Having accomplished his mission, he was in 1816 appointed secretary to the Society, a post he filled with great success until 1830, when he became rector of Watton, Hertfordshire. Here, until his death on February 24, 1850, he took an active part in promoting, both by tongue and pen, almost every work having for its object the spread of religious truth whether at home or abroad. He was one of the founders of the Evangelical Alliance. Of his religious writings, which were collected in 16 vols. (1853), the most popular are: *A Help to the Study of the Scriptures*, *The Christian Student*, and *A Treatise on the Lord's Supper*. He also edited *The Christian's Family Library*, a work consisting of 40 vols. His *Christian Psalms* went through 59 editions in seven years. It formed the basis of the well-known *Hymnal Companion*, now in use in more than 2000 churches, prepared by his son, EDWARD HENRY BICKERSTETH, born in 1825, who, from 1885 till his death in May 1906 (Evangelical) Bishop of Exeter, was author of *Yesterday, To-day, and For Ever*, and other poems (see his Life, 1907).—HENRY BICKERSTETH (1783-1851) in 1836 became Master of the Rolls, and was raised to the peerage as Baron Langdale; and ROBERT BICKERSTETH (1816-84) was Bishop of Ripon from 1857.

Bicycle. See CYCLING.

Bidar, a town in the Nizam's Dominions, near the right bank of the Manjra, a tributary of the Godavary, 75 miles NW. of Hyderabad. Formerly a place of importance, it is now remarkable chiefly

for its manufactures in a compound metal made of tin, copper, lead, and zinc, and called Bidderly ware. Pop. 13,000.

Bidassoa, a river which, rising in Spain, forms the boundary between that country and France, and, after a course of 33 miles, falls into the Bay of Biscay at Fuenterrabia. During the Peninsular war its banks were the scene of several conflicts.

Biddeford, a city of Maine, U.S.A., on the right bank of the Saco River, 6 miles from its mouth in the Atlantic Ocean, opposite the town of Saco (q.v.). It has manufactures of cotton and woollen goods and machinery, and there is a large trade in timber. It was settled about 1630, and named by settlers from Biddeford in England. Pop. 18,000.

Bidder, GEORGE PARKER (1806-78), born on the edge of Dartmoor, was from his amazing powers of mental arithmetic exhibited by his father as a phenomenon, and was known as 'the Calculating Boy.' He studied at Edinburgh University, and was associated with Robert Stephenson as a railway engineer. He planned the Victoria Docks in London, helped to found the first electric telegraph company, and was most skilful in parliamentary committee work. His son was an eminent K.C.

Bidding-prayer, a form of exhortation, always concluding with the Lord's Prayer, enjoined by the 55th canon of the Anglican Church, in 1603, to be used before all sermons and homilies. Except in cathedrals and the university churches, it is now seldom used. Such a form was anciently used for the communicants or believers after the dismissal of the catechumens, and was pronounced by the deacon, each petition beginning with the words 'Let us pray for,' and the people responding at the end of each with 'Kyrie Eleison,' or some such words. *Bidding* means properly praying, so that *bidding prayers* means saying prayers; but as this sense of the word bid went out of use, *bidding prayer* was thought to mean enjoining prayer, and finally the form of injunction.

Biddle, JOHN, sometimes called the founder of English Unitarianism, was born in 1615, at Wotton-under-Edge, in Gloucestershire, and in 1634 entered Magdalen Hall, Oxford, where he took his degree of M.A. In 1641 he was elected master of the free school in the town of Gloucester; but having embraced certain opinions in regard to the personality of the Holy Spirit, at variance with those held by the majority of Christians, he was thrown into gaol, December 1645. He was summoned before the parliament at Westminster, tried, and thrown into prison. The famous Westminster Assembly of Divines undertook to 'settle' Biddle's case, but their arguments had only the effect of strengthening his previous convictions. His work on the Holy Spirit, issued in 1647, was burnt by the hangman as blasphemous. In 1648 he published a *Confession of Faith concerning the Holy Trinity*, which was followed by another tract containing the opinions of the Fathers on the same question. Parliament had passed an act declaring the denial of the Trinity a crime punishable by death, and the Westminster Assembly besought parliament to have Biddle executed. Parliament did not respond to this appeal, he never was brought to trial, and personal friends secured his liberation by becoming surety for his appearance when wanted. Cromwell's Act of Oblivion gave him full liberty. He now commenced to gather a congregation of those whom he had converted to his opinions. Twice during the Commonwealth Biddle suffered severely for his creed, and in 1655 was banished to one of the Scilly Isles. In 1658 he was released, and continued to preach in London till the death of Cromwell, and also after the Restoration, until June 1662, when he was again apprehended and fined in £100.

He could not pay it, so was committed to gaol, where he died 22d September of the same year. See UNITARIANS.

Biddle, NICHOLAS, an American financier, born at Philadelphia, January 8, 1786, graduated at Princeton College, and became an energetic member of the legislature of Pennsylvania. In 1823 he was appointed president of the United States Bank, and held that post till 1836. He was next chosen president of the United States Bank of Pennsylvania, but resigned in 1839; two years later the bank became insolvent. He had conducted its affairs with great skill, integrity, and prudence, and he published a series of letters in vindication of his administration. A presentment was made against him for fraud, which was never followed up. Biddle had considerable literary taste, and for some time edited *The Philadelphia Portfolio*, contributing many articles to its pages. By request of the president of the United States, he compiled from the original papers a *History of Lewis and Clarke's Expedition to the Pacific Ocean*; also *The Commercial Digest*, a volume put forth by Congress. He died February 27, 1844.

Bideford, a 'little white seaport town' of North Devon, on both sides of the Torridge, 3½ miles above its confluence with the estuary of the Taw, and 9 miles SW. of Barnstaple. The name signifies 'by-the-ford,' and is pronounced *Bid-de-ford*, like that of its American daughter. The old bridge of 24 arches and 226 yards long, which unites the two divisions of Bideford, was widened and restored in 1864 and 1925. The church was rebuilt, all but the tower, in 1864. Manufactures are ropes, sails, earthenware, and leather; and these are exported, as are oak-bark, corn, flour, linens, woollens, iron, &c. Vessels of 500 tons can get up to the quay. Population, 9000. A place of Viking sepulture, Bideford was the port whence Sir Richard Grenville sailed on his last voyage, and it figures much in Kingsley's *Westward Ho!*

Bidpai, also PILPAY, the reputed author of a collection of fables and stories widely circulated both in the East and West, of which the earliest extant form exists in an Arabic version of about 750 A.D. The original was an Indian collection of tales which are not now in existence, but of which the *Panchatantra* (q.v.), and to a lesser degree the *Mahābhārata* (q.v.) and the *Hitopadesa* (q.v.), contain each a part, though in a modernised and artificially elaborated form. Of this Indian original, the classical and elegant Arabic version, *Katibah wa Dimnah*, already spoken of, is a substantially faithful reproduction. It was not made, however, direct from the Sanskrit, but from a lost Pehlvi version, the parent also of an incomplete old Syriac version, dating from about 570, which was discovered in the episcopal library at Mardin at the time of the Vatican Council, and published in 1876 by Bickell with an introduction by Benfey. Save this, every known version of the book descended directly or indirectly from the Arabic version of Abdullah-ibn-Almokaffa of 750. This work as it exists is made up of three elements: Indian, Persian, and Arabic, three chapters being Persian, and six appearing first in the Arabic version, while twelve chapters are of Indian and Buddhist origin. Of these last, five correspond to the five chapters composing the *Panchatantra*, two appear in the first book thereof, three are found in the *Mahābhārata*, and two seem to have fallen out of the Indian literature altogether. However, if Buddhism originated the book, it was Islam which transmitted it to Europe, for no fewer than five different translations were made from the Arabic version—into Syriac (10th or 11th century); Greek (about 1080 by Symeon Seth); Persian (about 1120,

a somewhat free translation, known as that of Nasrullah); Hebrew (13th century by Jacob ben Eleazar); and Old Spanish (1251, from which Raimund's Latin version was made in 1313). A somewhat earlier Hebrew version formed the basis of the *Directorium* (about 1270) of John of Capua, a converted Jew; which in turn gave rise to German by Graf Eberhard (about 1480); Spanish, the *Exemplario* (1493); Italian, (Doni's *Moral Filosofia* (1552), and Firenzuola's *Discorsi degli Animali* (1548); French; English (1570); Danish (1618); and Dutch (1623) versions. The English edition was a rendering by Sir Thomas North (1570) of the Italian *Moral Filosofia* of Doni. The Persian of Nasrullah gave birth to the *Anwārī-Suhailī*, or 'Nights of Canopus the Star' (late in 15th century), of Husain Wā'iz, which in turn gave rise to the Turkish *Humāyūn Nāmāh*, or 'Imperial Book' (early in 16th century).

As to the original transmission of the book from India, the story is told that the Persian king Khosrū Nūshirvān (531-79), hearing of its existence in India, despatched his physician Barzōye to India to procure and translate a copy of it into Pehlevi, the literary dialect of Persia. Its translator into the older Syriac version was an ecclesiastic named Būd (or Bōd); into Arabic, the elegant and accomplished but ill-fated scholar, 'Abdullah Ibn-al-Mokaffa.' Of this work each chapter forms a story which is supposed to have been related to a king of India by his philosopher, Baidaba or Bidpai, to point some moral. The story itself is simple in form, but usually branches out into a number of parenthetical stories, conversations, and sayings. In many of the stories animals play parts, and act as if men and women. With the chapter on the lion and the ox, or how two friends may be set at variance by a crafty interloper—the fifth in De Sacy's text—we enter on the original Indian book. The name given to the book, in Arabic *Kalīlah and Dimnah*, in Syriac *Kalīlag and Damnaq*, is derived from the Indian names of the two jackals who take a principal part in this story. Perhaps the most pleasing story in the book is that of the ringdove, or the love of sincere friends. The 14th chapter in De Sacy, the story of the king and his dreams, is unmistakably Buddhist, the Brahmins in it being presented in the most odious light. In this story none of the parts are taken by animals. The account of the mission of Barzōye to India, and his biography, are given in all the versions except the later Syriac just before the story of the lion and the ox, and after the table of contents. The prominent part which asceticism plays in this biography Benfey connects with Buddhism, then in full vigour in India.

An eclectic text of the Arabic version was edited by Silvestre de Sacy (Paris, 1816), and has been translated into English by Knatchbull (Oxford, 1819), and into German by Phillip Wolff (2 vols. Stutt. 1839). The later Syriac version was edited by Professor Wright (1884), and was translated into English, with an excellent introduction, by the late I. G. N. Keith-Falconer (1885).—See also Loiseleur Deslongchamps, *Essai sur les Fables Indiennes* (Paris, 1838); Max Müller, 'On the Migration of Fables,' in vol. iii. (1880) of *Chips from a German Workshop*; and Rhys Davids, *Buddhist Birth Stories* (1880).

Biebrich, a town on the right bank of the Rhine, 2½ miles S. of Wiesbaden; pop. 20,000. It has the castle of the Dukes of Nassau, and manufactures cement, manures, sulphuric acid, and stucco.

Biel. See BIENNE.

Bielefeld, a busy town in the Prussian province of Westphalia, picturesquely situated on the little Lutter, at the foot of the Teutoburger-Wald,

28 miles SW. of Minden. The old walls which withstood the last siege in 1673, have been converted into promenades. Bielefeld is the centre of the Westphalian linen-trade. Its industries include spinning, weaving, bleaching, dyeing. Among its manufactures are silk, motor-cars, cycles, weighing and other machinery, cranes, pulleys, tobacco and meerschaum pipes. Pop. 80,000.

Bieleff, an ancient town of Russia, in the government of Tula, on the Oka, 160 miles SSW. of Moscow; pop. 10,000.

Bielitz, or BIELSKO, a town of Poland, on the left bank of the Biala, 60 miles SW. of Cracow by rail. It has dye-works, and carries on a trade in woollen cloths, wine, and salt. Pop. 18,000.

Biella, a town of north Italy, in the province of Novara, 56 miles NE. of Turin by rail. It has some manufactures (including felt hats), and is the seat of a bishop. Pop. 20,000.

Biëlo-ozëro ('White Lake'), a lake in the government of Novgorod, Russia, covering an area of 432 sq. m., its length being about 25 miles, and its breadth 20. Its surplus waters are conveyed by the Sheksna River into the Volga, and canals unite it with the Onega, Sukona, and Dwina.—**BIELO-ZERSK** is an old wooden town on the south shore of the lake; pop. 5000.

Bielopol, a town of Ukraine, 106 miles NW. of the city of Kharkov, with extensive brandy distilleries; pop. 16,000.

Bielostok. See BIALYSTOK.

Bielshöhle, a stalactite cavern in the Harz Mountains, on the right bank of the Bode. It was discovered about 1672, but first made accessible in 1788. Its entrance is 108 feet above the bed of the stream, and its total length is 230 yards.

Bielsko. See BIELITZ.

Bienne, in German BIEL, a town of Switzerland, in the canton of Bern, 56 miles SW. of Basel by rail, beautifully situated at the base of the vine-clad Jura, and at the foot of the Lake of Bienne. Population, 35,000, engaged in the manufacture of watches, leather, cotton, &c. Bienne is mentioned as early as 814. From 1262 it belonged to the bishops of Basel; but in 1352 it entered into an alliance with Bern, and after the Reformation was essentially a free and independent city until 1798, when it was annexed to France. In 1815 it was united to Bern.—The LAKE OF BIENNE, lying 1424 feet above sea-level, extends 9 miles north-eastward along the base of the Jura Mountains, its greatest breadth being 3 miles. It receives the surplus waters of Lake Neuchâtel by the Thiel, by which river it again discharges its own. Its maximum depth is 256 feet. Towards its head is the Île St Pierre, to which Rousseau retired for two months in 1765.

Biennials, or BIENNIAL PLANTS, are plants which do not flower in the first season of their growth, but flower and bear fruit in the second season, and then die. The most familiar example is perhaps that of the common foxglove (*Digitalis*). Many of our cultivated plants are biennials, as the carrot, turnip, parsnip, parsley, celery, &c., and many of the most esteemed flowers of our gardens, as stock, wallflower, honesty, &c. But plants which in ordinary circumstances are biennials, often become Annuals (q.v.), when early sowing, warm weather, or other causes promote the earlier development of a flowering stem, as is continually exemplified in all the kinds already named. If, on the other hand, the flowering of the plant is prevented—or, in many cases, if it is merely prevented from ripening its seed—it will continue to live for a much longer period; the same bed of parsley, if regularly cut over, will remain productive

for a number of years, while a normally annual plant like *mignonette* may be kept growing for two years or more if its flowering be carefully prevented.

Bierstadt, ALBERT (1830-1902), born at Dusseldorf, went as a child to the United States, but studied painting in Europe. In 1859 he visited the Rocky Mountains, and settling near or in New York, made the artistic representation of mountain scenery his life-work.

Bies-Bosch, a marshy sheet of water with an area of 77 sq. m., between North Brabant and South Holland.

Bigamy, in the canon law, meant the contracting of a second marriage. The term was applied to a second marriage even when the prior marriage had been dissolved. Second and subsequent marriages, while allowed by the canon law, were regarded with disfavour. Thus a person contracting such a marriage was not admitted to holy orders. The nuptial benediction was not given at the second marriage of a woman, though it was given at the marriage of a widower with a virgin.

In the ordinary English use of the word, bigamy is the entering into a second marriage while the former marriage still subsists. In England it originally was a purely ecclesiastical offence, but by the statute of 1604 it was made a felony. The enacted law on the subject is now contained mainly in the Offences against the Person Act, 1861. The offence is punishable with penal servitude for not more than seven nor less than three years, or with imprisonment for not more than two years, with or without hard labour. The gravity of the crime varies greatly according to the particular circumstances and the degree of deceit practised. The Act of 1861, while declaring the second marriage generally felonious, excepts certain cases. These excepted cases are: (1) A second marriage contracted elsewhere than in England or Ireland by any other than one of his Majesty's subjects. But a person who is a British subject is guilty of the crime whether the second marriage took place within or without the king's dominions. (2) A second marriage by one whose husband or wife has been continuously absent from such person during the seven years preceding the second marriage, and has not during that time been known by such person to be living. (3) A second marriage by one whose first marriage had been validly dissolved before the celebration of the second marriage. The divorce must be a legal one—that is to say, must be legal by the law of the country where the divorced parties were domiciled at the time.

To constitute the crime, the first marriage must have been valid according to the law of the country where it was celebrated, and the second marriage must also have been in a form recognised by the law of the place where it was celebrated. It must also be proved that the first wife or husband of the accused was still living at the date of the second marriage. It is now settled in England that, even though the first husband or wife has not been absent for the period of seven years preceding, or has been heard of during that period, it is nevertheless a good defence to a charge of bigamy if it can be proved that the accused had an honest *bona fide* belief, founded on reasonable grounds, that his or her first wife or husband was dead. The man or woman who, in knowledge of the facts, goes through the ceremony of marriage with the bigamist may be indicted as a principal in the second degree in England, and as art and part in Scotland. Formerly the first wife or husband was not a competent witness for the prosecution; but, by the Criminal Justice Administration Act, 1914, the husband or wife of a person accused of bigamy may be called as a witness either for the prosecu-

tion or for the defence, and without the consent of the person accused.

In Scotland bigamy is a crime both at common law and under an Act of 1551. The essentials of the crime are the same in Scots as in English law. But in Scotland seven years' absence of the accused's original spouse is not recognised as a conclusive defence, the rule simply being that the accused cannot be convicted if he or she proves that at the time of the second marriage he or she had reasonable grounds for believing that the other spouse was dead.

Marriage between persons one of whom is already lawfully married to another is of course void. But in Scotland *bona fide* belief—i.e. error of fact on the part of either of these persons—is sufficient to legitimate the children of the union. The same rule formerly held in England, but no longer does so.

In the United States the law on this subject is in most respects uniform with the law of England. It has, however, been decided in the United States, contrary to the rule now established in England, that even an honest belief in the death of the other spouse will not avail as a defence to the spouse who remarries within the limit of seven years provided for in the bigamy statute. It is no defence that polygamy is a religious privilege sanctioned by local usage.

Bigelow, the name of several notable Americans, of whom the most important are—(1) ERASTUS BRIGHAM (1814-79), born in Massachusetts; invented, while yet a lad, looms for weaving suspender webbing and piping cord, and afterwards constructed a machine for making knotted counterpanes, and a valuable loom for weaving carpets.—(2) JACOB (1787-1879), physician, born in Massachusetts; graduated at Harvard University in 1806, and early became known as a skilful botanist. He practised for over forty years in Boston, and filled several chairs at Harvard. His professional publications are numerous, and the single-word nomenclature of the *American Pharmacopœia* of 1820, afterwards adopted in England, is largely due to him.—(3) JOHN (1817-1911), born at Malden, New York, was managing editor of the *New York Evening Post* from 1850 to 1861, when he went as consul to Paris. From 1865 to 1866 he was United States Minister in France, and in 1875-77 was secretary of state for New York. He wrote *Lives of Fremont* (1856), Cullen Bryant (1886), and S. J. Tilden, besides editing Franklin's *Autobiography* from the original MSS. which he found in France (1868; new ed. 3 vols. 1875) and Franklin's *Complete Works* (1886). He contributed the article FRANKLIN to this *Encyclopædia*.—His son POULTNEY, born in 1855, a travelled journalist, has written much on the Emperor William II. and things German and Russian.

Bigg. See BARLEY.

Biggar, a town of Lanarkshire, 28 miles SW. of Edinburgh. The Collegiate Church of St Mary was founded in 1545. Dr John Brown, author of *Rab and his Friends*, was a native. Pop. 1500.

Biggleswade, a Bedfordshire urban district, 40 miles N. of London, with a great corn-market; pop. 5400.

Bighorn. See SHEEP.

Big Horn, a navigable river of the United States, and the largest affluent of the Yellowstone, rises near Fremont's Peak in the Rocky Mountains, in the NW. of Wyoming. It has a north-east course of about 350 miles.

Bignoniaceæ, a tropical order of sympetalous dicotyledons, closely allied to the Scrophulariaceæ (q.v.), from which they may be distinguished by the longitudinal dehiscence of the capsule, and by their winged exalbuminous seeds (see TRUMPET-

FLOWER). They are in many cases noble trees, and some of them afford valuable timber, among which may be named *Bignonia leucoxydon*, a tree of Jamaica, which is sometimes imported for cabinetmakers, &c. under the name of green or

Bignonia radicans.

yellow ebony; some Brazilian species (*Jacaranda brasiliensis*) furnish exceedingly hard and beautiful timber. Not a few of them are climbing shrubs (lianas), and the tough shoots of *Bignonia kerere* are used for wicker-work in Guiana. *Bignonia alliacea*, a native of the West Indies, is remarkable for its strong alliaceous smell; the leaves of *Bignonia Chica* afford the red colouring matter called Chica (q.v.).—Some are herbaceous; of these the most important is *Sesamum* (q.v.).

Bigod, the name of a family founded by a poor Norman knight, which acquired the earldom of Norfolk in the reign of Stephen. The second earl, Roger, took a prominent part in securing Magna Charta; in 1306 the earldom became extinct.

Bigorre, a mountainous district of South-west France, formerly belonging to Gascony, but now for the most part embraced in the department of Hautes-Pyrénées. Tarbes (q.v.) has been the chief town since the days of the Romans. See BAGNERES.

Big Sandy River, also called *Chatterawah*, a navigable affluent of the Ohio, formed by the junction of two branches which rise in Virginia. The west fork runs through Kentucky, and the east fork in its lower course bounds these states.

Bihac, or BIHAČ, a strong fortress-town of Yugoslavia, in north-west Bosnia, on the Una, near the Croatian border. It was the scene of frequent contests during the Turkish wars, and there is a fine monument to the Austrians who fell in the campaign of 1878. Pop. 6200, mostly Mohammedans.

Bihar. See BEHAR, BEHAR AND ORISSA.

Bihari, one of the Hindu group of Indian languages. See INDIA.

Bihé, a fruitful native kingdom of Portuguese West Africa. The eastern part rises to a lofty plateau, where the climate is delightful. Bihé was an important caravan centre, as the only route across the continent south of the Congo passed through it. The trade in slaves and ivory was once great. Area, 2500 sq. m. Kagnomba, the king's capital, is more than 3 miles in circumference. See Major S. Pinto's *How I Crossed Africa* (1881).

Bijanaghur. See VIJAYANAGAR.

Bijapur, a decayed city in the Bombay Presidency, 160 miles SE. of Poona. It was for centuries the flourishing capital of a powerful kingdom, but fell therewith under various dynasties in succession, Hindu and Mussulman, till in 1686 it was captured by Aurangzebe. It passed during the

early part of the 18th century into the hands of the Mahrattas, and became British in 1848. Now that a gradual decay has done its worst, Bijapur presents a contrast perhaps unequalled in the world. Lofty walls of hewn stone, still entire, inclose the silent and desolate fragments of a once vast and populous city. With the exception of an ancient temple, the sole relic of aboriginal domination, the ruins are Mohammedan, and consist of beautiful mosques, colossal tombs, a fort, with an inner citadel, a mile in circuit. The British government has done everything to prevent further decay. Pop. 28,000. See Fergusson's *Indian Architecture* (1876).

Bijawar, a petty native state in the Bundelkhand Agency, with an area of 973 sq. m. Diamonds and ironstone are found, but the country is poor and hilly. Pop. 125,000.

Bijbharu', BIJBHARA, or BIJBAHAR, the second city in Kashmir state, India, on the Jhelum, 25 miles SE. of Srinagar; pop. 5000.

Bijnaur, a town of the United Provinces, 3 miles E. of the Ganges. Sugar, Brahmanical threads, and cotton cloth are manufactured. It is a seat of the American Methodist Mission and headquarters of the Jâts. Pop. 17,000.—The district of Bijnaur, in the N. of the Rohilkhand division, contains more than a dozen towns with a population of over 5000. It has an area of 1800 sq. m., and a pop. of 800,000.

Bikaner, the capital of a Rajput state, lies in a desolate tract, 250 miles WSW. of Delhi. It is surrounded by a battlemented wall of 3½ miles in circuit, and from a distance presents a magnificent appearance; but many of the carved buildings for which it is notable are situated in narrow and dirty lanes, and the people are extremely dirty. There are seven Jain monasteries. Pottery, stone-cutting, and carving, the making of a white candy and of blankets, are amongst the industries of the place. Population, 70,000.—The state contains 23,300 sq. m., and a pop. of 660,000. The Rajputs are the dominant race; but Jâts form the great body of the inhabitants. The greater part of the state is a dreary, undulating plain interspersed with shifting sandhills, grass, and jungle bushes. The horses, cattle, and buffaloes of Bikaner are famous. The climate is remarkable for extreme changes of temperature.

Bikh is an Indian poison. See ACONITE.

Bilbao, a town of Northern Spain, the capital of the Basque province of Vizcaya (Biscay), is situated in a mountain gorge on the Nervion, 8 miles SE. of its mouth at Portugalete. Bilbao is well built; the principal streets are straight and the houses substantial; but there are no public buildings of particular note. Five bridges span the river, which divides the old town from the new. The old fame of Bilbao's iron and steel manufactures is attested by the terms *bilbo*, 'a rapier,' and *bilboes*, 'irons'—both common in Elizabethan writers. Bilbao has shipbuilding yards, dry docks, and tar-distilleries, as well as iron and steel works, but the city is commercial rather than industrial, being the principal port in northern Spain and the outlet for the rich iron-mines of the district. Great Britain takes most of the iron ore exported. Other exports are wine (for America) and rope-sole shoes. The chief imports are British coal and coke, Norwegian dried cod, Swedish timber, and petroleum. The narrow bed of the Nervion has repeatedly been widened and deepened so as to permit vessels of 4000 tons to come up to the town at high tide; the river-mouth has been protected, and many ships come only to the outer harbour. A free depôt was opened in 1920.

Thousands of emigrants embark annually for the Argentine. Bilbao enjoys excellent railway and electric tramway facilities on the whole, but the railway route to Madrid is devious, and consequently Bilbao's inconvenient connection with the south of Spain hinders its development as a main gateway of the peninsula. The town has grown rapidly; the population, in 1887 not much above 50,000, had in 1920 increased to over 114,000. Bilbao was founded in the year 1300 by Diego Lopez de Haro under the name of Belvao—i.e. 'the fine fort'—and soon attained great prosperity. In the 15th century it was the seat of the most authoritative commercial tribunal in Spain. It suffered severely in the wars with France, first in 1795, and again in 1808, when 1200 of its inhabitants were slaughtered in cold blood. During the Carlist struggles Bilbao has stood two great sieges, Zumalacarréguy here receiving his death-wound in 1835, whilst in 1874 the place was vainly besieged and heavily bombarded by the forces of Don Carlos for four whole months.

Bilberry. See WHORTLEBERRY.

Bil'bis, an old Iberian city of Spain, 2 miles E. of the modern town of Calatayud (q.v.), in the province of Saragossa, chiefly celebrated as the birthplace of the poet Martial, but also famed for its highly tempered steel blades.

Bilcock. See RAIL.

Bilderdijk, WILLEM, a Dutch poet and philologist, was born at Amsterdam, 7th September 1756. While studying law at Leyden, and afterwards, when practising at the Hague, he devoted himself assiduously to literature and poetry. On the invasion of Holland by the French he repaired to Brunswick, and afterwards visited London, where he supported himself by lecturing and teaching. In 1806 he returned to Holland, where he was received as one who had done his country honour; and the newly-elected king of Holland (Louis Bonaparte) appointed him president of the new Institut^e at Amsterdam, and also made him his own instructor in the Dutch language. Bilderdijk afterwards resided at Leyden and then at Haarlem, where he died 18th December 1831. His contributions to poetic literature were very numerous; but though his lyrics especially contain many beauties, yet, with one or two exceptions, none of his poems display any remarkable originality, or any great wealth of imagination. He also made valuable contributions to the exposition of the older monuments of Dutch literature, and wrote a history of the Netherlands. He was strongly conservative in his tendencies, theological and other. His collected poems have been edited by Da Costa (Amsterdam, 1856-59).

Bile is a fluid secreted from the blood by the liver. One part of it is destined to serve in the process of digestion; the other to be eliminated from the system. It is coloured yellow in man, and in carnivorous and omnivorous animals; it is green in vegetable feeders. The primary cells of the liver (the hepatic cells) separate the bile from the blood of the portal vein, and discharge it into small ducts, which unite to form larger ones, and eventually the right and left hepatic ducts. The latter unite to form the common hepatic duct, which is soon joined by that of the gall-bladder (the cystic duct). This junction forms the common bile duct, which pierces the second part of the duodenum, and running obliquely in its wall for a short distance, opens on its mucous surface.

Bile is constantly being secreted, more copiously after food; while the duodenum is empty, most of it passes up the cystic duct into the gall-bladder where it is stored. But when the contents of the

stomach are carried past the opening of the common bile duct, a copious flow of bile takes place into the duodenum, where it is mixed with the food, in order to aid the further processes of digestion.

The composition of human bile is on the average of

Water	about 86 per cent.
Bile-salts	" 9 "
Mucin	" 2 "
Other organic substances	" 2 "
Inorganic substances (ash)	" 0.6 "

The *bile-salts* (glycocholate and taurocholate of soda) are the most important constituents. If an animal membrane be wetted with a solution of these salts, it allows fatty substances to filter through it much more readily than if pure water or a solution of an inorganic salt be used; and this property aids in the absorption of fatty foods by the intestine. The bile-salts also assist in the emulsification, and to a certain extent, in the solution of fats. The *mucin* gives bile its viscid consistence. The other organic constituents include *fats* and *soaps*; *cholesterin*, chemically an alcohol, a crystallisable substance which is usually the chief constituent of biliary calculi or gall-stones (see CALCULUS); and the *bile-pigments*. The ash contains a trace only of iron, most of that derived from broken-down blood corpuscles being stored in the liver for future use.

Human bile has the specific gravity of about 1026 (water = 1000), is of a ropy consistence, with usually a yellowish-brown colour; does not readily mix with water, but sinks therein, and only after repeated agitation becomes diffused through the water, which then assumes a frothy appearance resembling soap-suds. Bile has a bitter taste and a faint musky odour. Besides aiding in the digestion of fats, bile stimulates the various muscular fibres of the intestine, and thus aids both the absorption and the propulsion of its contents; while the mucus it contains acts as a lubricant. It has also an antiseptic action, diminishing the putrefactive changes of the intestinal contents. Should, from any cause, the elements of the bile be in excess in the blood, or should the liver suspend the function of secreting it, not only is digestion imperfectly performed, but the general health suffers from the impure condition of the blood, and the patient is said to be *bilious*. On the other hand, the bile may be secreted, but its escape interfered with, and then its reabsorption will produce Jaundice (q.v.). See also the articles LIVER and DIGESTION.

BILIOUS ATTACK.—When the functions of the liver are temporarily interfered with, and particularly the secretion of bile diminished, most often in consequence of imprudence in eating or drinking, a *bilious attack* results. The liver, however, is rarely if ever affected alone, the stomach and intestines being also disordered; in most cases the stomach is probably the first to suffer. There are pain and discomfort in the abdomen, usually headache, and a yellowish discoloration of the skin and whites of the eyes; the tongue is furred and the appetite impaired, and the temper often becomes very irritable. Vomiting and diarrhoea often occur, and are in such a case salutary processes. The administration of a purgative is beneficial; and the food taken, if any, must be small in amount, simple, and readily digestible—e.g. milk with potash water, toast, biscuits, &c. See LIVER.

Bilge (sometimes spelled BULGE) is the part of the bottom of a ship nearest to the keel, and always more nearly horizontal than vertical. A ship usually rests on the keel and one side of the bilge when aground. The name of *bilge-water* is given to water which finds its way into the bilge or lowest part of a ship, and which, when not drawn off by the pump, becomes dirty and offensive.

Bilharzia (*Schistosomum hæmatobium*), a formidable Tiematode parasite of man in the portal system and renal veins, causing inflammatory lesions, hæmaturia, stone, and many complications. It is common in Africa; in Egypt about a third of the native population is infected. The worm is in some respects very divergent from the usual 'fluke' type. Thus the sexes are separate, and the male (10–15 millimetres in length and white in colour) has the margins of its flat body folded inwards to form a canal, in which the female (cylindrical and 15–20 mm. in length) is carried until fertilisation is effected. The fertilised females migrate into and tend to choke small veins, especially in the region of the bladder. The hard-shelled eggs have a terminal spine, and contain a ciliated embryo when they pass out from man in the urine. In water or in moisture the ciliated larva emerges and enters a fresh-water snail (species of *Planorbis*, *Bullinus*, *Melania*), as Dr R. T. Leiper discovered. The larva becomes a sporocyst, which gives rise to daughter-sporocysts, and inside these cercariæ develop. (See FLUKE.) The fork-tailed cercariæ leave the snail and swim in the water or creep along by means of their two suckers. They enter the human skin, especially if there is a scratch or wound; they pass into the lymphatic system and thence into the venous system, or into the venous system directly. They may also enter by the mouth in drinking-water. In stored water they die in thirty-six hours; and they are very sensitive to tabloids of sodium bisulphate. The chief source of infection is from unfiltered water used in washing and watering. Another species (*S. mansoni*), reported from man in Brazil, has eggs with a lateral spine; another (*S. japonicum*) occurs in man and cat, in the arterial as well as in the venous system, in Japan and China, and is associated with enlargement and cirrhosis of the liver. The cercariæ enter through the skin from the water of the rice-fields, or the like. See E. Brunpt, *Précis de Parasitologie* (1910), and R. T. Leiper, *Journ. Royal Army Medical Corps*, xxvi. (1915).

Biliary Calculi. See CALCULUS.

Bilimbi. See CARAMBOLA.

Bilin', a town of Bohemia, on the Bila, 5 miles SW. of Teplitz, and famous for its mineral springs, which belong to the alkaline group, and are remarkably rich in native carbonate of soda. The waters and their various mineral constituents are exported in great quantities, and the springs are largely sought by sufferers from gastric, catarrhal, or scrofulous complaints. The town, from 1464 the seat of the princes of Lobkowitz, whose castle rises near by, is surrounded with basalt crags, and in its vicinity is a remarkable isolated clinkstone rock, 1754 feet high, Borzenberg or Biliner Stein. Pop. 8000.

Bill, in Natural History, the horny, toothless, and lipless jaws of birds. (a) *Structure*.—The foremost bones of the skull (mainly, the premaxillæ, but also the maxillæ and nasals) are elongated in variable degree and form, and are covered with a horny sheath. The same is true of the lower jaw or mandible, and the result is a bill. The upper and lower portions are generally equal, but the upper is longer in birds of prey. The edges, usually more or less sharp, sometimes (e.g. in goosander) exhibit saw-like notches not unlike teeth. In the majority of cases the bill is not sensitive, the distribution of nerves being restricted

to a wax-like patch (the *cere*) at the base of the upper part of the beak. In aquatic birds, such as ducks and snipes, which feel for their food in the mud, this sensitive skin is carried forward almost to the point; and the bill of the woodpecker is also very richly supplied with nerves. The nostrils are usually far back near the cere, but often lie farther forward, most markedly perhaps in puffins.

(b) *History*.—No living birds have teeth. With the evolution of the class these structures have been lost. The fossil birds of America (*Odontornithes*) exhibit teeth, within sockets in *Ichthyornis*, simply in grooves in *Hesperornis*. But even in these forms the characteristic bones of the upper part of the bill—the premaxillæ—were toothless, and probably insheathed in a horny beak. The primitive bird *Archæopteryx* was also provided with numerous uniform teeth. From the beginning of the Tertiary Period onwards no toothed birds are found. Traces of teeth, however, still persist. Geoffroy St Hilaire (died 1844) observed small tooth-papillæ in the embryos of certain parrots, and this observation has been repeatedly confirmed. The presence of the characteristic tooth-substance dentine has even been asserted. The tortoise tribe have also lost their teeth, and here again the presence of rudimentary teeth in embryos (*Trionyx*) proves that the toothless state is secondary. That birds get on well without teeth is evident enough, but it is difficult to give a physiological explanation of their absence. The very spongy character of bird bone, obviously inconsistent with teeth, the sharp antithesis between the skin structures of birds and those of reptiles, the disuse resulting from the developed parental care which supplies the young with food, the general nature of the nutrition, and the freedom from fighting which birds must at first have enjoyed ought probably to be taken into account; but some deeper physiological reason is still required. This is peculiarly difficult when we recall the very varied nature and habit of toothless vertebrate animals—e.g. pipe-fish, toads, turtles and tortoises, birds, duckmole, echidna, ant-eaters, and some whales.

(c) *Relation to Function*.—The bill is chiefly used in seizing and dividing the food, but also for fighting, preening, nest-building, &c. It varies most with the nature of the food. It is hardest in birds which live on fruits, seeds, and flesh; sharpest in the birds of prey; more delicate in insectivorous forms; and softest in those which pick their food out of the mud. It is shortest in the granivorous, and longest in the marsh birds. In birds of prey the beak is hooked, and often notched; in fishing-birds it is usually very large; in those which catch flying insects the gape is particularly wide. Water birds often exhibit cross plates at the margins, between which the water taken in with the food is allowed to escape. Wallace noted an interesting correspondence between the length of a humming-bird's bill and the depth of the flower-tube which it visits. Finally, it is worth noting that beaks sometimes exhibit (e.g. in fowls and sparrows) pathological variations, which closely resemble what in other birds are the normal forms. See BIRDS.

Bill, in its general acceptation, means a formal written paper or statement of any kind; originally, it was applied to any sealed document, being derived from Lat. *bullā*, 'a seal' (Middle English, *billē*; English Law Latin, *villa*). It has a number of technical applications, for which see below; and see also PARLIAMENT; INDEMNITY; EX-CHEQUER BILLS; ATTAINDER, COSTS, HEALTH, MORTALITY, RIGHTS, VICTUALLING (BILL OF).

BILL, in the criminal law of England, is the formal name of a written accusation of serious crime preferred before a grand jury. If that body by a majority finds 'a true bill,' the prisoner or party accused is thereupon tried upon an indict-

ment before a petty jury, whose verdict determines his guilt or his innocence; but if the grand jury find 'no true bill,' the accused is at once set at liberty. In the latter event, however, other bills may be sent up against him. This whole procedure is more quickly and cheaply managed in Scotland by the system of public prosecutors, who take the responsibility of proceeding to trial without a preliminary public investigation. See **JURY**, **CRIMINAL LAW**, **TRIAL**.

BILL, or **BILL OF COMPLAINT**, was the name given in the English Court of Chancery, prior to the Judicature Act of 1873, to the formal statement of the facts and prayer for relief submitted by a plaintiff to the court. This is now in every case a Writ of Summons (q.v.) and Statement of Claim, and is not greatly different from a well-drawn summons and condescendence in the Scottish courts. In the United States the bill consists of the statement, the charges, the interrogatories, the prayer of relief, and the prayer of process.

BILL-BROKERS are persons who, being skilled in the money-market, the state of mercantile and personal credit, and the rates of exchange, engage, either on their own account, or on that of their employers, in the purchase and sale of foreign and inland bills of exchange, and promissory notes. They are to be distinguished from discount-brokers, or bill-discounters, whose business consists in discounting or advancing the amount of bills of exchange and notes which have some time to run before they come due, on the faith of the credit of the parties to the bill. Thus a bill-broker might purchase a doubtful bill and discount it by means of his own credit. The distinction between them is not, however, in practice a very broad one. See **BILL OF EXCHANGE** (below), **BROKER**, **PROMISSORY-NOTE**.

BILL-CHAMBER is a department of the Court of Session in Scotland which deals with summary business—so called because formerly both summonses and diligence or execution were for the most part commenced by a writ called a bill. These bills went to the whole court, but the necessity for them has been in most cases abolished by the reforming legislation of the 19th century. Since 1813 the Bill-chamber is presided over by a single judge called the Lord Ordinary on the Bills, and during the sittings of the Court of Session the duty is taken by the junior or last appointed judge of the court; but in vacation-time the business of the Bill-chamber is performed by a rotation of judges.

In the few cases where bills are still in use in processes of diligence—e.g. in bills for letters of arrestment or inhibition on the dependence of an action where the will of the summons contains no warrant for that purpose—application is made in the Bill-chamber, and a *fiat* is written on the bill and signed by the clerk of the bills (Act of Sederunt, 1913, E. chap. iii.). In modern practice the main business of the Bill-chamber consists in dealing with applications for suspension of diligence, or of decrees of inferior courts, or of decrees in absence in the Court of Session, and with applications for interdict. All such proceedings were formerly instituted by bills, but now commence with notes, which, however, must still pass through the Bill-chamber. The Lord Ordinary on the Bills, on passing the note, may sist execution of the charge, or decree, or order *interim* interdict, as the case may be, pending the final decision of the case in the Court of Session. If, indeed, no appearance has been entered, and no answers lodged in the Bill-chamber, the Lord Ordinary now has power, on passing the note, to pronounce a final judgment granting the prayer of the note in whole or in part. The jurisdiction of the Bill-chamber has been

largely supplemented by statute. Thus, under the bankruptcy statutes, the Lord Ordinary on the Bills may award, refuse, or recall sequestration, and deal with many matters arising in the course of bankruptcy proceedings. Any order made in England or Ireland by a competent court in bankruptcy, or in the winding-up of a company, may be enforced in Scotland on being registered in the Bill-chamber and certified by the clerk of the bills. Again, in vacation the Bill-chamber exercises many of the powers of the Court of Session—e.g. in petitions for interim appointment of public officers, and in applications under the Judicial Factors Acts, the Trusts Acts, and other statutes. See **COURT OF SESSION**, **INTERDICT**.

BILL OF ADVENTURE is a writing by a merchant, stating that goods shipped by him, and in his name, are the property of another, whose *adventure* or chance the transaction is—the shipping merchant, on the other hand, undertaking to account to the adventurer for the produce.

BILL OF EXCEPTIONS is a statement of objections, by way of appeal, against the ruling of a judge who is trying a case with a jury in the Court of Session. The objection may be that the judge has misdirected the jury in point of law, or has improperly rejected or admitted evidence. The bill is argued before four judges, and if it is sustained a new trial is ordered. The phrase was prior to the Judicature Act also used in England in the same sense, but is now merged in the 'motion for a new trial' (see **TRIAL**). In the United States the phrase is used for a statement of the objections of either party to the ruling of the judge during the trial. Exceptions must be taken at the time, and must be properly certified by the court to whose rulings they are taken.

BILL OF EXCHANGE, a document purporting to be an instrument of pecuniary obligation for value received, and employed for the purpose of settling a debt in a manner convenient to the parties concerned. The original and simple purpose of a bill is to obviate the necessity of cash payments in the settlement of accounts between parties at a distance from one another. Thus, A and B are two merchants in London; and C is a merchant in Cadiz. A owes C £1000; and C owes B a like sum. Instead of A sending cash to C, and C to B, C draws a bill for £1000 upon his debtor A, and sends it on to B, who receives the amount from A; so that the transaction throughout is settled, without a farthing in money being sent from Cadiz to London, or from London to Cadiz. It is easy to see that a bill may, in a similar manner, pass through several other hands before it finally comes back to A, and is paid by him. Another simple idea of a bill is this: One person owes another £100 for goods, for which he is to have credit for three months. The creditor, however, not being able conveniently to be without the money for that length of time, gets from the debtor an obligation or bill bearing that the £100 is to be paid in three months. This bill, being a negotiable instrument, will be discounted by a banker, or other capitalist, who now stands in the position of the creditor, and receives payment when the bill is due. Thus, a bill of exchange performs two kinds of offices in commerce—it saves the transmission of coined money, and it enables creditors not only to fix down debtors to a day of payment, but to get the use of a sum equivalent to the debt (less a small discount) before it is properly due.

The origin of this important mercantile instrument is usually attributed to the Jews and Lombards, when banished from France and England in the 13th century. It is certain that hitherto no trace of such bills has been discovered either in the Roman code, or in any other system of

ancient jurisprudence. The first notice of them in modern times occurs about the middle of the 12th century, and by the end of the 14th they had got into general use in all the commercial states of Europe. In England, from about the middle of the 14th century down to the time of James I., and for many years after, bills of exchange were restricted to the purposes of foreign commerce. What are called inland bills—i.e. bills drawn by and upon persons resident in this country—were not employed much earlier than the reign of Charles II., and even then they were regarded with distrust and jealousy by the English judges. Another restriction upon bills of exchange was, that the privilege of their use was confined to merchants. But all restraints on such instruments gradually yielded to the wants and conveniences of society, and now any one capable of making a contract can be a party to a bill transaction, without regard to position, calling, or occupation. In Scotland inland bills were put on the same footing with foreign bills by an act of the Scottish parliament passed in 1696. Numerous enactments were passed from time to time, until in 1882 a measure became law, known as the Bills of Exchange Act, 1882 (45 and 46 Vict. chap. 61), which was intended to codify the existing law relating to bills of exchange, cheques, and promissory-notes. Besides doing this, the act introduces certain changes into the existing law, and in particular it assimilates in nearly every respect the laws of the three kingdoms in regard to bills or notes. Differences still exist in the following points: A bill does not in England, as it does in Scotland, operate as an assignation in favour of the holder of a debt due by the drawee to the drawer; the act does not alter the former rules as to bankruptcy in Scotland, nor in regard to the sevenennial prescription or limitation, and the summary methods of enforcing payment, which continue to differ to some extent in each country; and in Scotland consideration is not required to support a bill as it is for simple contracts in England. The laws relating to bills in the United States, and in the various British colonies, are similar to the English law.

A bill of exchange is defined to be a written and unconditional order, addressed by a person who is called the drawer, to another person called the drawee, desiring him to pay a certain sum of money to a specified person, or his order, or to bearer, within a certain time after its date, or after it is presented for payment, or on demand. If the drawee signs the bill in token of his agreeing to this request, he is called the acceptor. A *Promissory-note* (q.v.), though differing in form, is in all essentials equivalent to a bill. It is, in fact, simply a bill in which the drawer and the acceptor are identical. A bank-note is a promissory-note issued by a banker, payable to bearer on demand, and a bank *cheque* is a bill of exchange drawn on a banker. Subject to certain special provisions they are regulated by the same rules as other bills. For the constitution of the bill itself no particular form of words is necessary, provided its characteristic qualities clearly appear on the face of it, as a pecuniary instrument and an unqualified order. A bill of exchange is only good for a certain sum in money; such an instrument for the delivery of *goods* or property other than money would not be a bill. But although no particular words are required in a bill or note, it is always advisable to adhere, as much as possible, to their customary form. The only restrictions in regard to amount are that no bills or notes can be issued or negotiated in Scotland for less than 20s. (8 and 9 Vict. chap. 38), and that notes for less than £5, payable to bearer on demand, cannot be issued in England, nor, except by bankers, in Scotland or Ireland.

Besides the other requisites mentioned, bills of exchange must be duly *stamped*. The regulations on this subject are contained in the Stamp Act, 1891, and are to be found in almanacs and other publications in common use. The omission of the stamp, or using a stamp of insufficient amount, cannot be subsequently rectified; the bill is altogether void, and the parties to it are liable to a penalty of £10. A bill payable on demand, however, which is only liable to a stamp-duty of two-pence, may be stamped with an adhesive stamp subsequent to its issue, but the above penalties are still enforceable. The duties on bills drawn out of the United Kingdom are denoted by adhesive stamps, to be affixed by the holder of the bill before negotiating it.

The following is the usual form of an inland bill of exchange (for foreign bills, see below):

£100.

LONDON, 2d January 19—.

(Stamp) Two months after date [or 'at sight,' or 'on demand,' or 'at — days after sight'], pay to Mr E. F., or order [or 'to me, or order,' or 'to bearer'], One Hundred Pounds, for value received. A. B.

To Mr C. D., Merchant, Bristol.

From this form it will be seen that there are usually three parties to a bill of exchange, these three being: (1) the *drawer* (A. B.); (2) the *acceptor* or *drawee* (C. D.), to whom the order is addressed; and (3) the *payee*, or party in whose favour the bill is drawn, and who is entitled to receive the contents (E. F.). The transaction, however, may be simply between the drawer and acceptor, without the interposition of a third party; and there are other modifications and changes of form, according to the circumstances of the case, and the mode in which it is desired to have the bill negotiated. The bill, being thus in proper form, and duly authenticated, is then presented for acceptance, which may be defined to be the act by which the drawee evinces his consent to comply with, and be bound by, the request contained in the bill of exchange directed to him; or, in other words, it is an engagement to pay in money the bill when due. Acceptance in the case both of inland and foreign bills of exchange must now be in writing on the bill, and signed by the acceptor, or some person duly authorised by him; the mere signature of the drawee, without any additional words, being sufficient. There are certain precautions to be observed before accepting. The drawee should, upon presentment for acceptance, and before he accepts, assure himself that the signature of the drawer is genuine, and that there has not been a fraudulent substitution of a larger sum than that originally inserted in the bill by the drawer. And if the drawee accept a forged bill, or a bill for a larger amount than that originally named by the drawer, he will nevertheless be liable to pay a *bonâ fide* holder. There is also acceptance *supra protest*, which takes place where, after a bill has been protested for non-acceptance, but not before, any person, not already liable on the bill, may accept it *supra protest*, which acceptance is so called from the manner in which it is made. Where the drawee of a foreign bill cannot be found, or is not capable of making a contract, or refuses to accept, this description of acceptance is frequently made in order to save the credit of all or some of the parties to the bill, and prevent legal proceedings. In this country it is called an acceptance for the honour of the person or persons for whose use it is made, and in France an acceptance *par intervention*. The drawer or indorser of a bill may insert in it the name of a person to whom the holder may resort in case of its non-acceptance. In place of simply assenting to the order, the drawee may *qualify* his acceptance by making payment dependent on

the fulfilment of a condition, as 'the delivery of bills of lading.' An acceptance may also be qualified as to the amount or currency of the bill or the place where it is payable. An acceptance 'payable at Coutts' Bank' would be general, but 'payable at Coutts' Bank only' would be a qualified acceptance. It must be observed that while the acceptance or indorsement may be qualified, the bill itself as drawn must be an unconditional order.

The bill as a negotiable instrument, being thus complete in all its parts, may either be held by the drawer or other payee till due, when it is presented for payment to the acceptor, or it may at once be transferred by *Indorsement* (q.v.), the indorsee taking it for its value at maturity, and in the meantime cashing or discounting it to the holder. There may be a succession of indorsees, the last of whom is entitled to payment; and to him all the other indorsees, as well as the drawee and drawer, are bound. Like the acceptance, the indorsement may be qualified or conditional, and it may also be *restrictive*, as 'pay A. B. only,' thus prohibiting the further negotiation of the bill. An indorser may also add the words 'without recourse,' so as to negative his own responsibility to the holder. This method of disposing of bills without a concurrent obligation by indorsement is better known and more practised in the United States than in England. Instead of discounting his bills in the usual form through a banker, a merchant in New York will sell his bills to a broker or dealer in this kind of instrument, the price paid being according to the state of the money-market and the creditworthiness of the acceptor. In such cases the purchaser stands in the place of the drawer, undertakes all risks, and as custodian of the bill has the power of legally exacting payment.

When the bill arrives at maturity—that is, on the day when its payment is due—it must be presented for payment to the acceptor at the place or address mentioned in the bill; if none is mentioned, then at his place of business or residence. If the holder fail to duly present, the drawer and indorsers will be relieved of liability; even the known death or bankruptcy of the acceptor will not excuse presentment for payment. It may, however, be dispensed with if the acceptor is a fictitious person or is not bound to pay the bill, if the parties expressly waive presentment, or if, after reasonable diligence, the acceptor cannot be found.

When the bill is not payable on demand or at sight, three days of grace are added to the currency of the bill, on the last of which the bill becomes payable. Should the last day of grace fall on a common-law holiday, as Sunday, Christmas-day, or Good Friday, or a National Fast or Thanksgiving Day, the bill is payable on the preceding day; but if the last day of grace is an ordinary statutory bank holiday, the bill is due on the succeeding business day. If the acceptor is unable to pay, he may endeavour to arrange for a *renewal* of the bill—i.e. the drawing of a new bill with an extended currency. Failing such an arrangement, if the bill is not paid on presentment, the holder must give immediate notice of its dishonour to the drawer and indorser, from whom he can then claim payment. To preserve this recourse, it is not necessary to note or protest the bill, this act being now necessary only in the case of foreign bills, and, in the case of inland bills, as a preliminary to acceptance or payment for honour, or to preserve the right of summary diligence in Scotland. The acceptor, as primary obligant, may then be proceeded against in a very speedy form in England under the 'Summary Procedure Act, 1885,' and in

Scotland by the still more direct method of summary diligence, without further action, under the old statutes of 1681 and 1696.

By the Statute of Limitations (see *LIMITATION*) in England, and Prescription (q.v.) in Scotland, bills and notes (except bank-notes) become of no effect in six years after their due date, but the creditor may still recover on the original claim in satisfaction of which he received the bill.

Accommodation Bill.—A bill in its legitimate sense is a document constituting a debt, and as such is beneficial to all parties connected with its negotiation. A owes B £100. A cannot conveniently pay the amount, while B is in need of it; B draws on A, and C (a banker) discounts—i.e. for a consideration pays the amount to B. B thus gets his money at once, A obtains time, while C makes a profit for advancing. These facilities have had the effect of inducing bills to be resorted to for raising money where no value is given, and in which one party gives the use of his name for the *accommodation* of another. In the above case, for example, let us suppose that A does not owe B, but yet accepts B's draft. If C discounts the bill, it is immaterial whether he knows that A has got value or not—as an onerous holder, he can compel payment from A if B cannot pay the bill. But if merely in B's hands, the amount is not recoverable from A if the latter can prove that no value was received by him. Accommodation bills, being a simple and easy way of raising money on credit, often give rise to fraud and rash speculation, and many attempts have been made to suppress the system; but it is difficult to do so without unduly interfering with the negotiation of *bona fide* bills.

Foreign Bill of Exchange is a bill which is either both drawn and accepted abroad; or drawn by a person residing abroad on a person in this country, or the reverse. The risk of miscarriage to which these bills are liable in their transmission to distant countries has given rise to the custom of drawing them *in sets*—that is, writing out two or three of the same form and tenor, and transmitting them to the payee by different channels, so that if one or two of the individuals of any set are lost, the other might reach its destination. The first of the set that is presented and accepted is alone entitled to payment, and payment of it discharges the acceptor; but foreign bills, of course, may also be drawn singly. The following is the usual form of a foreign bill:

£1000. JAMAICA, 2d January 19—.
Fifty days after date pay this First of Exchange (second and third of same time and date unpaid) to the order of A. B., One Thousand Pounds sterling, value received. C. D.

To E. F., London.

If a bill be drawn in this country upon a correspondent abroad, or a foreign house, it must be stamped; and when drawn abroad it must be stamped by the holder, before he can present it for payment, or indorse, transfer, or otherwise negotiate it within the United Kingdom (Stamp Act, 1891, sect. 35). Formerly a bill drawn or payable in Scotland or Ireland was foreign in England; but such bills are now inland, and the same regulation extends to the islands of Man, Guernsey, Jersey, Alderney, Sark, and adjacent islands (Bills of Exchange Act, 1882, sect. 4). The same act, sect. 72, provides that the liabilities of the drawer, the acceptor, and indorser shall be governed by the laws of the countries in which the drawing, acceptance, and indorsement respectively took place. The duties of a holder are determined by the law of the place where the act is to be done, and the due date depends on the law of the place where the bill is payable. Thus, a bill drawn in Paris or

Berlin on London is entitled to three days of grace, but a bill drawn in London on either of these places has no days of grace, these not being recognised by the laws of France or Germany. If a foreign bill is dishonoured by non-acceptance or non-payment, it must be duly protested, or the drawer and indorsers are discharged. In the case of foreign notes protest is not necessary, but it is always advisable if the makers of the note are to be sued abroad, as the law of the foreign country may require protest. Except in a few points, the laws of most commercial countries agree with those of the United Kingdom in regard to bills. See treatises on Bills of Exchange by Byles, Hamilton, and Chalmers.

BILL OF HEALTH. See **HEALTH.**

BILL OF LADING is a receipt from the master of the vessel to the shipper (usually termed the *consignor*), undertaking to deliver the goods—on payment of freight—to some person whose name is therein expressed, or indorsed thereon by the consignor; and the delivery of this instrument— independently of the actual delivery of the goods— will suffice to transfer to the party so named (usually termed the *consignee*), or to any other person whose name he may think fit to indorse thereon, the property in such goods; and by the Bills of Lading Act, 1855, it is provided that every consignee and every indorsee shall have transferred to him all rights of suit, and be subject to the same liabilities in respect of the goods as if the contract had been made with himself. The bill of lading is a document of title to the goods, and the indorsement and delivery of it to a *bonâ fide* transferee for value defeats the lien of the unpaid vendor of the goods, and his right to stop the goods *in transitu*. A bill of lading is conclusive evidence of the shipment made as against the master or other person signing it. Bills of lading are thus the proper evidence of the contracts of a 'general ship'—i.e. where the ship is not chartered wholly to one person, or where the charterer takes sub-freights. They are made out in three copies, one of which is retained by the shipper, another sent to the consignee, another left with the master. A 'mate's receipt' is generally given until the more formal bill of lading is made out. The bill mentions the name of the master, the destination of the ship, the goods, the consignee, and the rate of freight (see also the article **SALE**). A bill of lading thus fulfils three functions: (1) it is a receipt for the goods shipped under it; (2) it constitutes the contract for the carriage of the goods; (3) it is a negotiable document of title to the goods.

In the United States, an act making uniform the law of bills of lading has been passed in New York and several other states.

BILL OF SALE, in the law of England, in modern usage is a document whereby a sale or mortgage of personal chattels is effected, without an actual transfer of the possession of the chattels to the purchaser or mortgagee. Documents of this kind, assigning goods without delivery to the assignee, are (subject to certain exceptions) within the scope of, and regulated by, the statutes known as the Bills of Sale Acts. The main purpose of these acts is, by means of a system of compulsory registration, to prevent false credit being given to persons who remain in possession of goods after parting with the ownership. The acts apply only to bills of sale of 'personal chattels,' a term which includes goods, furniture, and other articles capable of transfer and delivery, as well as growing crops, when assigned separately from the land, and trade machinery. Certain assignments of book debts, however, are now, under the Bankruptcy Act, 1913 (sect. 14), required to be registered like bills of sale. Bills of sale, within the meaning of the

Bills of Sale Acts, are of two kinds: (1) absolute, such as are executed with the intention of conferring absolute ownership on a purchaser; (2) those granted by way of security for the payment of money. Absolute bills of sale are comparatively rare; but bills of sale used as a means of creating a right in security over goods are of great importance in the business life of England.

Bills of sale granted by way of security are now required to be in accordance with the form prescribed in the schedule to the Bills of Sale Act, 1882 (45 and 46 Vict. chap. 43), otherwise they are altogether void. The prescribed form plainly expresses the nature of the contract as to the loan and the security for the loan; and the policy of the legislature in prescribing this form is to prevent needy persons being entrapped into signing documents of charge which they do not fully understand, and which might be made instruments of oppression. The other chief statutory requisites in the case of a bill of sale by way of security are that it must be attested by one or more credible witnesses; that it must contain a true statement of the consideration, which must not be less than £30; and that it must be registered within seven days of its execution. To the registrar must be presented a true copy of the bill, of every schedule or inventory annexed to it, and of every attestation of its execution. An affidavit must be filed at the same time verifying the date, the due execution, and the attestation of the bill, and stating the names, addresses, and occupations of the grantor and of every attesting witness. When the goods covered by the bill of sale are seized or taken possession of, they must not be removed or sold for five days; and during that period the grantor of the bill of sale may apply to the court to restrain the removal or sale of the goods. The priority of bills of sale is determined by the date of registration. The registration must be renewed every five years.

The Bills of Sale Acts do not extend to Scotland or Ireland. For Ireland, however, acts have been passed modelled on the English statutes. In Scots law, on the other hand, a real right over movable goods, whether absolute or by way of security, cannot, as a general rule, be effectually constituted unless the possession of the goods is transferred.

The expression bill of sale, in the Bills of Sale Acts, does not include transfers or assignments of any ship or share of a ship. But the document of title used in England and Scotland for passing the property in, or mortgaging, a ship, under the Merchant Shipping Act, 1894, is known as a 'bill of sale.'

In the United States the effect of a bill of sale is to transfer the property in the thing sold. By Act of Congress (R.S.U.S., sect. 4170) every sale or transfer of a registered ship to a citizen of the United States must be accompanied by a bill of sale setting forth the certificate of registry.

BILL OF SIGHT is an entry of imported goods of which the merchant does not know the quantity or quality. This is permitted to save time by the Customs authorities on sworn information. The bill must be made perfect in three days by indorsing the particulars required for warehousing, payment of duty, or delivery free of duty. If the entry is not completed within a month, the goods are sold.

BILL OF STORE is a licence from the Customs authorities to reimport into the United Kingdom dutiable British goods formerly exported. Goods included in the bill are not regarded as foreign goods, and therefore are not liable to customs duties. The goods must in all cases have been reimported within five years from the time of exportation.

Billardiera, or **APPLEBERRY**, a genus of

twining Australian evergreen shrubs of the natural order Pittosporaceæ. The fruit is generally bluish when ripe, and is eatable, although not destitute of a resinous character which prevails in the order. Some species are cultivated in greenhouses in Britain.

Billet, in Architecture, an ornament belonging to the Norman style. It was formed by cutting a moulding—generally a round moulding—into notches, so that the parts left resembled billets of wood. When used in several rows, the billets and

empty spaces are placed interchangeably, as in the accompanying illustration.

Billet, FELIX (1808-82), physicist, born at Fismes (dept. Marne), who became professor at Dijon in 1845. He wrote on the change in volume in solids becoming liquid, on electric condensation, and on optics (the 'demi-lentilles' or 'bi-lentilles' of Billet 'being famous).

Billeting, or CANTONING, is a mode of lodging soldiers and their horses by quartering them on the inhabitants. Billets are of three kinds—(1) with full subsistence; (2) with partial subsistence; (3) without subsistence. In the first two cases officers and others must be satisfied with the usual fare of the householder, unless a special scale has been laid down, and neither bedding nor furniture can be demanded as a right; but 'attendance' can be required, and the use of cooking utensils. Billeting is a convenient method of utilising local resources, for by this means not only shelter but food may be provided with the minimum of trouble, and the food-supplies in the army transport conserved for emergencies. The regulations lay down that 'as a rule no payment will be made in respect of billets without subsistence.' The prices to be paid for food, forage, and accommodation are fixed for each year by the Army Annual Act (see ARMY), but in this country a much more liberal payment is actually made, including rent for billets without subsistence. Consequently the former unpopularity of the billeting system has greatly diminished, this being also partly due to the better behaviour of modern troops. The civil population naturally resented billeting, and one of the provisions of the Petition of Right (1628) was directed against the practice. The Mutiny Act, passed for the first time in 1689, declared that no housekeepers should be compelled to accommodate soldiers except on a recognised and fairly administered system. The chief civil magistrate of a town, on requisition from the military authorities, quartered the soldiers on the inhabitants as fairly as he could. This continued in England until 1745, when the liability to provide billets was limited to certain traders, and has so continued ever since; but the alteration was not made in Scotland until 1857.

The various Army Acts provide that only the keepers of public-houses of any description, if licensed to sell beer, wine, or cider to be drunk on the premises, are liable to have soldiers billeted on them, and livery-stable keepers to take in troop horses. The exceptions are canteens, and houses kept by foreign consuls or Vintners of the city of London. In 1909 extension was made to 'public buildings, dwelling-houses, warehouses, barns, and stables' on embodiment of the Territorial Force. The cases in which billeting is resorted to in the United Kingdom are either when troops are called

out in aid of the civil power, or when mounted troops are marching for several days, or when the Territorial Force is embodied; but whenever practicable they would be lodged in barracks, and dismounted troops are always moved by rail or sea for any distance exceeding one day's march. The order for the march is the authority for drawing billets. It is issued by the Secretary of State for War, and specifies the exact number of men and horses for which billets may be drawn, and the dates on which they are to be at each town. This document is called a 'route.' A billeting party of an officer, a sergeant, and one private per company precedes the main body by one day's march, and presents the 'route' to the billet-master (usually the chief constable) at the first halting-place, and communicates with the local health official. This official has a list of persons liable to have soldiers billeted on them, and from it he selects those whose turn it is to take them. The men and horses are told off to their billets by the billeting party in order that no delay may arise when the main body enters. After its arrival, the soldiers go to the houses on which they are billeted, all those belonging to one troop being quartered as near together as may be, for convenience of muster, and the horses near the men. The licensed victualler or householder is bound to provide each billet-holder with food, drink, and accommodation, either in his own house or somewhere at hand, and the livery-stable keeper has to provide straw, hay, and oats of good quality for each horse. The officers visit the houses, to see that the men really have one hot meal per day, instead of taking the value of it in money. The soldier may demand facilities for cleaning his arms and accoutrements. Accounts are paid by the Army Pay Department. Officers pay for their own food. Disputes often arise between the innkeeper or others and the officers of the regiment, and there are provisions of the Army Act framed to prevent irregularities on either side, but especially to safeguard the rights of the civilian.

In the United States a provision of the constitution specifies that no soldier shall in time of peace be quartered in any house without the consent of the owner, nor in time of war but in a manner to be prescribed by law.

Billiards (from old Fr. *billard*, 'a stick with a curved end,' 'a cue'; in English, introduced as the name of a game, and made plural). The origin of billiards is uncertain. The historian who plunges deepest into the mystery of the past is the author of *Modern Billiards*, the American textbook of the game, who refers to the travels of Anacharsis through Greece, 400 B.C., during which a game which might have been early billiards was seen; and also tells how Cathira Mora, king of Ireland, who died 148 A.D., left 'fifty billiard-balls of brass, with the pools and cues of the same material.' Others ascribe the invention of the game to Henrique Deguise, an artist who flourished about 1570. It was brought into fashion by Louis XIV. (middle of 17th century), whose physicians recommended him exercise after meals. Another party believe billiards to be of English origin, and it is mentioned by Spenser (*Mother Hubbard's Tale*, 1591) and by Shakespeare (*Antony and Cleopatra*, circa 1607). The earliest description of billiards in English is in Cotton's *Compleat Gamester* (1674). The bed of the table was then made of oak, or occasionally of marble. Slate beds were first used about 1827. The cushions were stuffed with flock: list was used later. India-rubber cushions were first manufactured about 1835. The pockets, called hazards, were at first wooden boxes, nets being employed soon afterwards. Each player pushed his ball with a mace made of heavy wood, and tipped at the broad end

with ivory. The game played was the white winning game (single pool), five or three up. A player holding his adversary's ball won an end (or life); if he holed his own ball he lost a life (hence the terms winning and losing hazards). In addition, a small arch of ivory, called a 'port,' and an ivory peg or 'king,' stood on the table, and certain scores appertained to passing the port and to touching the king.

In 1734 French billiards first appears in Seymour's *Court Gamester*. It is there stated that port and king are now wholly laid aside. Maces were still commonly used, but cue-playing was permitted. Cues, however, had no tips until the beginning of the 19th century. French billiards was very like single pool, a hazard counting two, a miss one, and a coup three. The game was played twelve up.

The losing game, in which a player scored for a losing hazard, was also occasionally played. About 1775 the carambole game (abbreviated to carom) is first heard of. A third ball, called the carom ball, was introduced. Winning hazards and cannons counted to the striker, losing hazards against him; and a baulk (now first so called) compelled the next striker to play out of baulk, as at present. Early in the 19th century the white winning and losing carambole game, now known as billiards, ousted all other varieties in this country. It is played on a table, the bed of which must measure 12 feet by 6 feet $1\frac{1}{2}$ inches, and is covered with a cloth, the nap of which shall run from the bottom to the top cushion. The cushions, which are now invariably made of rubber, are covered with cloth similarly to the bed, and no part of the cushion-rails may extend more than 2 inches or less than $1\frac{1}{2}$ inches beyond the edge of the bed. The cushions on the shorter sides of the table are known respectively as the top and bottom cushions, according to the run of the cloth. The distance from the floor to the top of the cushion-rail must not be less than 2 feet $9\frac{1}{2}$ inches, nor more than 2 feet $10\frac{1}{2}$ inches. The table shall be fitted with six pockets, one at each corner, and one pocket in each of the longer sides equidistant from the top and bottom cushions. The openings of the pockets shall be in accordance with the registered templates of the Billiards Association and Control Council, and those of the corner pockets measure a shade less than $3\frac{1}{2}$ inches at the fall of the slate. Three balls, each of which must not be less than $2\frac{1}{8}$ inches nor more than $2\frac{3}{8}$ inches in diameter, are used. These balls may be manufactured of any substance, but, practically, there are only three kinds in use—ivory, bonzoline, and crystallate. The two last-named have certain decided advantages over ivory, being less than half the price, and being unaffected by extremes of heat and cold, as well as being capable of standing a vast amount of rough usage; but, after contact with another ball, they come off at a more acute angle (especially so in the case of bonzoline) than that thrown by ivory balls, and lack the delightful 'life' of the natural product.

The French have long discarded pockets altogether, and play only a cannon game, with larger balls and a smaller table. The Americans added a fourth ball, and in their game cannons and winning hazards counted to the striker, and losing hazards against him. They then abolished the two side-pockets, in consequence of their interfering with cannon play (or, as the Americans still spell it, more correctly, carom). Of late years pocket-tables have been but little used in America, except for pool; and the size of the table has been gradually reduced to 10 feet by 5 feet; balls $2\frac{3}{8}$ inches in diameter. The four-ball game is now seldom played by experts, the three-ball French carom game having superseded it in match play. The skill

exhibited by the players has improved to such a remarkable extent that when Frank Ives challenged Jacob Schaeffer for the championship about 1892 it was agreed that the baulk-line should be drawn 18 inches from each cushion. These lines formed eight compartments, and, whilst all three balls were in each of these, only one carom was permissible. It was to minimise the effects of this 18-inch baulk-line that Ives invented what he termed the 'anchor' stroke, a name which was afterwards incorrectly given to the 'perpetual' cannon, by means of which Cook, Reece, Lovejoy, and other English professionals ran up such gigantic breaks. The first-named made the record of 42,746, and the game was reduced to such a farce that the Association was compelled to step in and introduce a new rule that not more than twenty-five consecutive ball-to-ball cannons should be allowed.

In 1825 John Carr was accepted as the first acknowledged champion of English billiards, but the title was never played for until 1870, when William Cook, senior, defeated John Roberts, senior, who assumed the title when Edwin Kentfield refused to play him in 1849. The championship has, subsequent to the first match in 1870, been held by John Roberts, junior, Joseph Bennett, W. J. Peall, C. Dawson, H. W. Stevenson, Melbourne Inman, W. Smith, and T. Newman. The last-named secured the title in 1922, and is probably the greatest player of them all, though it must be admitted that he possessed the great advantage of having the full benefit of the experience of his predecessors, and of all the improvements which have been made in the tables. There was no generally recognised code of rules for the game until the Billiards Association was formed in 1883, the committee of that body being composed of amateurs and professionals. This was a grave initial mistake, for in no other game or sport are professionals allowed to have a part in the management, but it was more than twenty years later before this very necessary alteration was made. In 1908 the Billiards Control Club came into existence, which made the state of affairs worse than ever, for the professionals were playing under the new code of rules, and the great bulk of amateurs under the other. This was the worst thing that could possibly have happened in the interests of the game, and an amalgamation of the two bodies took place in 1919. The new body was termed the Billiards Association and Control Council, Lord Lonsdale being elected president, whilst Mr Sydenham Dixon, who was president of the Billiards Association from 1906 to the date of its dissolution, was the chairman. Practically all the governing bodies of billiards all over the world became affiliated to the Billiards Association and Control Council of Great Britain, and the greatest of indoor games was at last placed upon a thoroughly sound footing.

No one has ever yet learnt to play a really fine game from a book, a series of lessons from an experienced teacher being an absolute necessity; but time or expense is saved if a beginner has a correct knowledge of the rudiments of the art when he takes his first lesson. Too much importance can scarcely be attached to the way in which a player stands at the table. The feet must be planted very firmly, for unless the body is perfectly firm an accurate delivery of the cue is impossible. The knees should be bent as little as possible, and the upper part of the body should be thrown well forward, for the nearer the eyes are brought to the line of sight the more likely is the stroke to be accurate. The arm of the bridge-hand should be extended to its full length, and should bear sufficiently on the table to ensure a steady position. The chief support of the bridge itself is the ball of

the thumb, which should be pressed firmly to the table. The tips of the fingers should grip the table, and all of them should be kept slightly apart, the distance between the third and little fingers being greater than that between the others. The thumb should be closed tightly against the hand, and the first joint of it should form the chief support of the cue. The arm which wields the cue should be kept as close to the body as is consistent with freedom of leverage, and the forearm should be perpendicularly above the cue. In making the great majority of strokes the cue must be held with the tips of the fingers and thumb. Whether you use all your fingers, or one, two, or three of them, is of no consequence, and you may do whatever comes most naturally to you in this respect, *but the cue must be held as loosely as possible.*

In striking the ball the cue must be kept as horizontal as possible, and there should be about 8 or 9 inches of cue in front of the bridge. Having taken careful aim—by placing the point of the cue in the closest possible proximity to the ball without actually touching it—draw the cue briskly backwards and forwards, *not more than half-a-dozen times*, and make the stroke without further hesitation. Having thoroughly mastered these preliminaries, the novice should engage the services of a reliable tutor.

Looock, *Side and Screw* (1901); John Roberts, jun. (1901); J. P. Mannock, *Billiards Expounded* (1904), infinitely the best book on the game which has yet appeared; C. Dawson (1904); Hemming, *Billiards Mathematically Treated* (2d ed. 1905); and Charles Roberts, *The Complete Billiard Player* (1911).

Billings, JOSH, the pseudonym under which Henry W. Shaw (1818-85), a land-agent at Poughkeepsie, New York, published facetious almanacs and collections of witticisms, the wit in which, however, was mainly due to their deliberate mis-spelling.

Billings, ROBERT WILLIAM, born in London in 1813, acquired, during a seven years' apprenticeship with John Britton, topographical draughtsman, a taste for and facility in the production of illustrations of historic buildings. Between 1838 and 1846 he produced illustrations on his own account of several churches and cathedrals, including his *Architectural Antiquities of the County of Durham*. The work, however, with which his name is permanently associated is his *Baronial and Ecclesiastical Antiquities of Scotland* (4 vols. 1845-52), with accompanying letterpress to its 240 illustrations. He wrote several works on architecture, and conducted a large business; amongst the buildings restored under his direction are the chapel of Edinburgh Castle and the Douglas Room in Stirling Castle, &c. He died 14th November 1874.

Billingsgate, a gate, wharf, and fish-market, a little below London Bridge, to the west of the custom-house. It was opened in 1558 as a landing-place for provisions; and in 1699 was made 'a free and open market for all sorts of fish.' The present handsome stone building was finished in 1874. The unpolished phraseology native, though not peculiar, to this quarter of London, has given rise to the proverbial use of the name.

Billington, ELIZABETH, a celebrated singer, was born in London about 1768. Trained by her father, a German musician named Weichsel, she appeared as an infant pianist in 1774; and in 1783, after a secret marriage with her singing-master, James Billington, she came out with brilliant success on the opera stage in Dublin. Returning to London in 1786, she was engaged at Covent

Garden at the then unheard-of salary of £1000 for the season. She appeared subsequently in Naples, Venice, Florence, and elsewhere, with the greatest applause. In 1799, her first husband being dead, she married a Frenchman, Felissent, but owing to ill-treatment she left him and returned to London, 1801, where she received nearly £4000 for six months, playing alternately at Covent Garden and Drury Lane. She retired from the stage in 1811, and died (1818) at her villa near Venice, not without suspicion of foul play from her husband. To a voice of great compass and the richest tone, trained in all the art of the Italian school, she added a fascinating personal beauty and grace.

Blitton, or BLITONG, an island in the Dutch East Indies, between the SE. of Banca and the SW. of Borneo. It is of round shape, about 50 miles in length by 45 broad, and 1855 sq. m. in area. To the north, which is hilly, the highest point rises 3000 feet. It is rich in iron, tin, and timber, and exports rice, trepang, edible birds' nests, seaweed, tortoise-shell, and wax. Its coasts are beset with rocks and islets. The best harbour is at Tandjong; Pandang is the chief town. Pop. 36,200, of whom over 100 are Europeans, and 10,000 Chinese, the rest mostly Malays.

Billom, a decayed town of Auvergne, in the French department of Puy-de-Dôme, 14 miles ESE. of Clermont. It was the seat of a university from 1455 to 1554. Pop. 3000.

Billon, a name (originally French) for a mixed metal sometimes used in coinage, consisting of gold or silver, with a large proportion of baser metal. For some small French coins, a mixture of four parts of copper to one of silver was used before 1810.

Bilma, in the French Sahara (18° 50' N. lat., 13° 30' E. long.), on the Kawar oasis, is included in the Niger Military Territory. Capital of the Tibu country (mostly in the Chad Colony), it is a resting-place of caravans crossing the desert.

Bilney, THOMAS, martyr, born about 1495, probably at Norwich, studied at Trinity Hall, Cambridge, and was ordained in 1519. He was opposed to the formal 'good works' of the schoolmen, and denounced saint and relic worship; and to these mild Protestant views he converted Hugh Latimer and other young Cambridge men. In 1527 he was arraigned before Wolsey, and on recanting, absolved, but was confined in the Tower for over a year. Stung by remorse, after two years of suffering, he began to preach in the fields of Norfolk, but was soon apprehended and condemned; and although allowed to receive the sacraments of the church from which he differed so little, he was burned as a heretic at Norwich, 19th August 1531.

Bilston, a town in South Staffordshire, situated on a rising-ground, about 2½ miles SE. of Wolverhampton, and forming part of its parliamentary borough. It has extensive iron and coal mines, iron-smelting works, iron-foundries for making machinery, besides works for manufacturing tin-plate goods, japanned and enamelled wares, nails, wire, screws, and coarse pottery. It is the centre, indeed, of the hardware trade, and consequently a very busy place. Fine sand, adapted for metal-casting, is found here. Pop. 28,000.

Biluchistan. See BELUCHISTAN.

Bima, a seaport of Sumbawa, one of the Sunda Isles, and capital of a state of the same name, is on a bay of the north coast, 100 miles E. of Sumbawa.

Bimana (Lat., 'two-handed'), a term first employed by the Göttingen anatomist Blumenbach (1752-1840) to describe the human species in con-

trast to other mammals. The separate order thus designated was recognised by Cuvier (1749-1832), and by most of his contemporaries and immediate successors. But in 1863 Huxley pointed out in his work entitled *Man's Place in Nature*, that as far as the term *Bimana* was concerned, it was equally deserved by some of the higher apes. In ordinary civilised man it is indeed obvious that the foot does not grasp in the way the hand does, but this is largely a matter of use and disuse. Many men in all races have learned to use their big toes as if they were thumbs, even to the extent, in more than one case, of playing on the violin; in less civilised races, the foot is not unfrequently used in rowing, climbing, and handiwork; and our own schoolboys and sailors exhibit considerable power of foot-grip. Haeckel notes how a young infant can grasp a spoon with the big toe as with a thumb. In short, man is four-handed if he chooses. The title is now rarely used, and man and monkeys are zoologically united in the old Linnæan order—Primates. See MONKEYS.

Bimbia, a district on the southern slope of the Cameroon Mountains in Africa, and on the northern bank of the river Bimbia. Part of German Cameroons (q.v.), it came under British mandate.

Bimetallism is the name given to a monetary system in which both gold and silver are on precisely the same footing as regards mintage and legal tender. At present, in the United Kingdom, gold to any amount can be brought to the mint and coined into sovereigns free of charge, and the legal definition of the pound sterling is a certain weight of gold of a certain fineness, &c.; and gold, and Bank of England notes representing gold, are the sole legal tender to any extent.

The silver coins of this country are at present only 'token' coins. The value of the silver of which they are made (even at the valuation before any depreciation of silver relatively to gold occurred) is below the nominal value—i.e. the silver in twenty shillings (reckoning silver as worth about 60 pence, or a quarter of a sovereign, an ounce) is not worth the gold in a sovereign. As a consequence the silver is coined only in limited quantities, and is legal tender only to the extent of forty shillings. This preliminary explanation is necessary, because it is often said in a loose inaccurate way that bimetalism exists *de facto* everywhere, because all nations use both gold and silver for coinage.

There is, however, a fundamental difference between standard coin and token coin. If by great discoveries of gold, or by the opening up of hoards in the East under civilising influences, the amount of gold brought to the mints were increased to a great extent, then there would follow a general rise in prices. This depends upon the principle that, other things remaining the same, an increase in the quantity of money will raise general prices. The only object of converting the gold into coins is to use the coins to spend, and the increase in spending power tends to force up prices. The theory is confirmed by the effects of the great discoveries of gold in Australia and California about 1850. Similarly, in the 16th century, when silver was standard money, the discovery of the rich mines of Potosi caused a great rise in prices.

But if under present conditions, in which no civilised nation coins silver to an unlimited extent, there were similar discoveries of silver, there would be no corresponding effect on prices. The only effect would be that silver would, reckoned in gold, become cheap or depreciated. The coinage, however, would not be increased, because the use of silver is strictly limited. If silver were a standard coin, then it would be coined in unlimited amounts, and when expended would tend to raise the prices of

commodities. The principle may be expressed thus: The quantity of standard money, other things remaining the same, determines the general level of prices, but the quantity of token money issued is determined by the general level of prices. When prices are high, *ceteris paribus*, more token money will be required as a circulating medium than when prices are low.

If we consider any particular country, the principal difficulty in the adoption of both metals as a joint standard is generally expressed by saying that the joint standard or double standard (to use the more familiar but less accurate term) would be in reality a fluctuating single standard. It is argued that, considering the variations in supply and demand of the two metals, variations must constantly occur in the relative market values of gold and silver considered as bullion. At the same time, it is said, if both are coined in unlimited amounts for unlimited payments, some definite legal ratio must be adopted at which they are to be coined and to circulate. If a contract for so many pounds can be fulfilled by the payment of either gold or silver, it must be assumed that in some way the equivalent amounts are determined.

But suppose, when large amounts have been issued at one legal ratio, the ratio for example at which gold coins are reckoned as equal to 15½ times their weight of silver, a disturbance occurs in the market ratio of the metals, such as it is alleged must occur with variations in supply or demand. Let it be assumed that silver becomes cheaper, so that the silver in twenty standard shillings is no longer worth one sovereign in gold, but only three-quarters. That means practically that any person can for three-quarters of a sovereign buy enough silver bullion to make into twenty standard shillings. Clearly under these circumstances no one would pay his debts in gold when by first exchanging it for silver, he would gain five shillings in the pound. On the other hand there would be a rush to melt down gold in order to get the cheap silver, and the gold would, if silver remained below the old legal ratio, be driven from circulation. Under the opposite conditions of silver becoming relatively dearer, it would be replaced by gold, and thus the conclusion is reached that the joint standard would be an alternating standard with the cheaper metal as the real standard at any time. This law, according to which the cheaper metal displaces the dearer, is known as Gresham's Law; and it is found, historically, that a very small difference between the market and the legal ratio will suffice in any particular country to drive the dearer metal from circulation. This theory has been repeatedly illustrated in the history of particular countries. Thus, in England in 1717, according to the ratio adopted by the advice of Sir Isaac Newton, gold was, compared with silver, overvalued about 1½ per cent., that is to say, it was so much more valuable as currency than as metal. Consequently the full-weight silver coins were withdrawn, and gold became the principal currency. In France, on the other hand, at the time of the great Revolution, silver was slightly overvalued, and thus became the principal currency, the gold being to a large extent driven from circulation.

The question then arises: What becomes of this dearer metal, and whence is the cheaper metal derived which must be coined to take its place? It is obvious that in any modern society, the gold or silver displaced will not be hoarded, nor is there any reason why the mere change in relative value should lead to a greater use of plate made of the dearer metal. Accordingly it seems inevitable that this dearer metal should be exported, in order to get the cheaper metal for coinage, for by parity of reasoning it cannot be drawn from hoards or plate

within the country. It is this consideration which is the foundation of the argument, that although one country alone might be unable to maintain both metals as legal tender at a fixed ratio, under a union of the principal commercial countries the system would be quite possible and perfectly stable. For, *ex hypothesi*, there would in this case be no place to which the gold, supposing it became dearer, could be exported, or from which silver to take its place could be obtained. Again, if under these conditions any disturbance in the ratio occurred, (supposing it possible) to the advantage, for example, of gold, the gold would be driven from circulation and converted into bullion. Thus there would be a great increase in the supply of gold, and a corresponding increase in the demand for silver, and it is maintained that the old ratio would at once be restored. This process of reversion to stability is known as the *compensatory action of the double standard*, and was the counterpart of Gresham's Law in the great controversy of the 'eighties.

If, then, the possibility of international bimetalism on a conventional basis is granted, it is requisite next to inquire into the advantages of the system, for in currency above everything the maxim *quæta non movere*, to let things alone, is held to be sound. The advantages claimed in the above controversy were twofold. *Firstly*, it was argued that if the main work of standard money was in the future thrown upon gold, there must be a great fall in prices from the level to which the world had been accustomed with both metals as standard money. It was alleged that the fall in prices that took place after 1874 was mainly due to the substitution of gold for silver as the standard by Germany and other countries, because, taking the world as a whole, the amount of gold had not sufficed to keep up the level of prices. It was further argued that, having regard to the increased use of gold for the arts and the diminished supply from the mines, this fall in prices would continue, or that there would be a continuous appreciation of gold, with a constant increase in the real burden of debts, and a disturbance of the real meaning of contracts and great friction in the adjustment of customary retail prices.

The term *appreciation*, as applied to gold, requires some explanation. If gold is the standard of value, it may be thought that its own value cannot change, just as a foot measure always remains of the same length—that a sovereign of full weight must always remain of the same value. But it is one thing to appoint by law that a certain amount of gold shall be coined into a certain number of sovereigns, and quite another to suppose that these sovereigns shall always exchange for the same amount of wealth. If, on the whole, a sovereign purchases more than it did, from whatever cause, that constitutes an appreciation of gold. An appreciation of gold is thus the same thing as a general fall in prices.

Seeing that the number of purchasable commodities is practically infinite, it is of course not easy to say even that a general fall is taking place, and it is still less easy to measure exactly the extent of the fall. For some commodities may be rising whilst others are falling. The general method adopted is to take certain important commodities as fairly representative. Thus the *Economist*, in its annual review, takes twenty-two commodities and compares their price with the price which was the average between 1845-50. Taking each of the average prices for that period as 100, the total would be 2200. In any subsequent year the actual change in price is worked out in these 'index numbers,' as they are called. Thus suppose during the given period the average price of wheat had been 60s. a quarter, and in some other year it

became 30s., we should have to change the index number from 100 to 50, that is, under it or half. If in adding up the total of the index numbers in any year we find a rise has taken place, then it is assumed this fairly measures the general rise in prices. It may be interesting to quote some of the principal changes in the 'index numbers.' A fluctuating rise took place from 1850 up to 1864 when the index numbers became 3787. This is equivalent to saying that on the articles taken there was an average rise of about 72 per cent. It would, however, obviously be a mistake to argue that all prices must have risen to that extent, especially when we consider that owing to the American civil war the price of cotton was abnormally raised. From 1864 to 1871 there was a fluctuating fall in prices, the index numbers in the latter year being 2590. Then a rise took place, the numbers in 1872, 1873, 1874, being respectively 2835, 2947, 2891. Thus in these years of inflation, as they are often termed, though there was a rise of about 31 per cent. on the original 'index numbers,' there was a still greater fall from the numbers of 1864. From 1874 there was a steady and rapid decline, until on 1st January 1880 the aggregate 'index number' was only 2023, which was lower than the original number, and lower than that of any year subsequent to 1850. It was this very remarkable fall in prices that constituted the appreciation of gold, and it was maintained by bimetalists that if silver were used to supplement gold as standard money the fall in prices would be checked, and that for the future the general level would remain more steady.

Secondly, the adoption of conventional international bimetalism (for that is the only system practically proposed) was advocated not only as a partial remedy for the appreciation of gold, but also as a preventive of fluctuations in the relative values of gold and silver. It was said that the depreciation of silver, caused by the monetary disturbance, injuriously affected our trade with silver-using countries, and that in effect this depreciation acted like a protective duty on imports into such countries, and a bounty on their exports. To these statements of alleged facts it was replied generally that our exports to the East, or silver countries, had largely increased, and that the exports from the silver countries, such as Indian wheat, were really stimulated by other causes—e.g. railways and reduced freights by sea. It is, however, undeniable that if gold prices on this side had remained at their old level, whilst at the same time silver had depreciated, the effects on our eastern trade would have been accurately described by the analogies of a protection duty in the one case and a bounty in the other. So far, however, as the gold prices of commodities fell in the same degree as silver, no such stimulus or restraint appeared to take place. A Manchester merchant might just as well sell to India for the same silver as before, even although it produced only 30 per cent. less gold, as sell to gold-using countries for 30 per cent. less gold, directly without the intervention of silver. Similarly, an Indian exporter had no advantage from cheap silver if he obtained for his exports 30 per cent. less gold wherewith to purchase silver.

Here, however, the question arose whether the depreciation of silver had not directly, to a large extent, caused the fall in gold prices. It is generally admitted that the effect of a bounty is to lower prices in the foreign country, and protective duties operate indirectly in the same way; and, similarly, it was maintained (especially by M. Cernuschi) that the depreciation of silver had lowered all prices measured in gold.

It will be observed that both of these advantages claimed for bimetalism depended upon questions

of fact; and the difficulty in obtaining information was the chief reason for the appointment of the Royal Commission in 1886. No one, however, denied that if by any means the relative values of gold and silver could be fixed, it would be beneficial to the world at large. Meie fluctuations are certainly an evil. The possibility of thus fixing and maintaining a ratio received strong practical support from the fact that for seventy years, in spite of great variations in the relative amounts of gold and silver produced, the existence of bimetalism in France, and the large use by other nations of silver as standard money, kept the ratio, apart from small variations due to exchange operations, at nearly 15½:1. It may also be said that an international convention, once established, would not be broken in the same capricious manner as a purely political treaty; for it may easily be shown that every nation makes the agreement in the first place with its own subjects, and that by breaking the agreement it would injure them more than any one else. There was really not much more apparent reason why, once established, the system should have broken down, than if all the nations had adopted the same system of weights and measures. In practice, however, the initial difficulties might be insuperable in spite of extremely unsatisfactory conditions in the relations of gold and silver from the monetary point of view.

The United States were compelled by the Bland Act to coin large quantities of silver every year; the Sherman Act (1890; repealed 1893) empowered the Treasury to increase its purchases of silver, but failed to maintain the ratio (see SILVER). The government of India also failed to maintain the ratio by stopping (1893) the free coinage of silver.

But any attempt to adopt gold as the sole principal standard throughout the world would, in Goschen's often-quoted opinion, produce a most disastrous monetary crisis, and thus the choice seemed to lie between an international agreement on a reasonable basis, and the reliance on the self-interest of each particular nation to make no further change through dread of further evil.

It is impossible even to mention in a brief article all the points of controversy on the question of bimetalism. Until the great and rapid fall in the value of silver compared with gold, it was apparently believed that from some curious but beneficial natural cause the ratio would remain fairly steady, and for about seventy years the variations were very small. Accordingly very little attention was paid to the question by economists, who for the most part were content with saying that it would be difficult for one country to maintain effectively a double standard. Again, when the depreciation set in, it was believed that it would be only temporary, but this belief has proved to be unsound.

The partial failure of the Latin Monetary Union to preserve an international *coinage* need not prejudice the case of a bimetallic union like that proposed by the United States. The Latin Union, proposed in 1865 and accomplished in 1868, was essentially a treaty between certain countries (France, Belgium, Italy, Switzerland) for an identical *coinage* (apart from the mere stamp) to be received as legal tender in each country. It was only accidentally bimetallic, and no special provision was made for the unlimited *coinage* of either gold or silver.

The greatly increased annual production of gold, owing to the African and other discoveries, since 1896, and the consequent steady rise in gold prices, has, however, greatly lessened the practical importance of the bimetallic question. A method of economising gold has also been sought by de-

pendent and other countries in what is known as the gold exchange standard. Under this system gold is reserved mainly for international payments, the internal currency being composed of token coins or notes.

To understand the subject in its historical bearings, the reader should consult the Reports of the Royal Commission (1886), of the Indian Currency Commission (1893), and of the Berlin Silver Commission (1894). On the monometallic side may be mentioned Fowler's *Appreciation of Gold*, Sir Robert Giffen's *Essays in Finance*, papers by Wells, and Laughlin's *Bimetalism in the United States* (1897). On the bimetallic side we may mention various essays by H. Cernuschi, H. H. Gibbs, Grenfell, R. Barclay, S. Smith, &c.; there is, besides, a valuable historical work by the Hon. Dana Horton called the *Silver Pound*, a *Treatise on Money, with Essays on Monetary Problems* (1897), by the present writer, and the *Standard of Value* (1912), by Sir David Barbour, may also be mentioned. The best book for the statistics of the question is Soetboer's *Materialen*, translated from the German for the use of the Royal Commission, and published in America by Atkinson.

Binary Stars. See STARS.

Binary Theory, in Chemistry, takes cognisance of the mode of construction of salts. It assumes that all salts contain merely two substances, of which either both are simple, or one is simple and the other a compound playing the part of a simple body. The best and most familiar illustration of the binary theory is common salt or chloride of sodium, NaCl, which is constructed of the metal sodium, Na, and the non-metal chlorine, Cl, and is at a glance seen to be a *binary compound* (a compound of two). Although this theory attracted much attention from 1837 to 1855, and was adopted by Liebig and other chemists, it never met with general acceptance, and has now been quite superseded. See ACIDS and SALTS.

Binche, a town of Belgium, in the province of Hainaut, 10 miles E. of Mons, manufacturing delfware and lace; pop. 11,000.

Bindrahan. See BRINDABAN.

Bindweed. See CONVULVULUS.—The Black Bindweed or Climbing Buckwheat (*Polygonum Convolvulus*) is a twining weed of the Polygonaceæ (q.v.), with convolvulus-like leaves. The seeds, but for their small size, might be used like Buckwheat (q.v.).

Bingen, an ancient town of Hesse-Darmstadt, Germany, is charmingly situated on the left bank of the Rhine, 39 miles SE. of Coblenz. Below the town is the celebrated *Bingerloch*, formerly a very dangerous point in the navigation of the Rhine, but in the year 1834 the sunken rocks were blown up. In the middle of the river stands the *Mauseturm*, the tower of Bishop Hatto (q.v.). Nearly opposite Bingen, in the Niederwald, is the colossal statue *Germania*, erected 1877-83 to commemorate the war of 1870-71. Pop. 10,000.

Bingham, JOSEPH, a learned English scholar and divine, was born at Wakefield in Yorkshire, September 1668. Educated at University College, Oxford, he was elected fellow in 1689 and college tutor two years later, but was obliged to resign his fellowship owing to an unfounded accusation of heresy in a sermon which he had preached in St Mary's on the meaning of the word 'Person' in the Fathers. He was at once, however, presented to the rectory of Headbournworthy in Hampshire, and here he commenced his laborious and learned *Origines Ecclesiasticæ, or Antiquities of the Christian Church* (10 vols. 1708-22). In 1712 he was preferred to the rectory at Havant near Portsmouth, and in 1720 he lost all his property in the great South Sea bubble. He died August 17, 1723.

Binghamton, a flourishing city of New York, at the junction of the Chenango and Susquehanna

rivers, 215 miles NW. of New York city. It is an important railway centre, and manufactures flour, engines, carriages, leather, and cigars. Pop. (1870) 12,692; (1890) 35,005; (1900) 39,647; (1920) 66,800.

Bingley, a town in the West Riding of Yorkshire, 5½ miles NW. of Bradford. It has a training college, and worsted, woollen, cotton, and paper manufactures. Pop. 19,000.

Binney, THOMAS, D.D., LL.D., a Congregational preacher, born at Newcastle in 1798, in 1829 settled in London. He laboured with great success (1833-69) in the new Weigh-house Chapel, near London Bridge, erected for him by his hearers. He died 24th February 1874. His most popular work was *Is it Possible to Make the Best of Both Worlds?* (1853). See *Lives* by Stoughton (1874) and Paxton Hood (1874).

Binocular. See OPERA-GLASS, MICROSCOPE.

Binomial, in Algebra, is an expression which consists of two terms, separated by + or -, such as $x+y$, $ab-cd$. Monomial, trinomial, polynomial are the names given to expressions consisting of one, three, more than three terms. The Binomial Theorem gives an expansion of $(x+y)^n$ into a finite or an infinite series of powers of x and y , when n is a number either integral or fractional, positive or negative, rational or irrational; thus $(x+y)^n =$

$$x^n + nx^{n-1}y + \frac{n(n-1)}{1.2}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{1.2.3}x^{n-3}y^3 + \dots$$

The series is finite when n is a positive integer. It was discovered by Newton about 1666, and was first published in 1704 in the second appendix to Newton's *Optics*. That particular case of the theorem when n is a positive integer was known to mathematicians prior to Newton (e.g. Briggs and Pascal), and Newton himself gave no demonstration of the truth of his theorem. Many demonstrations have been given by subsequent mathematicians, but the validity of most of them has been called in question. See Chrystal's *Text-book of Algebra*.

Bintang, an island of the Dutch East Indies, 40 miles SE. of Singapore; area, 454 sq. m. Gambir, rice, and pepper are exported.

Bin-turong (*Arctictis* = bear-marten), a genus of carnivores in the civet section. Its resemblance to raccoons, beside which it used to be placed, is entirely superficial. It is a slow arboreal and nocturnal animal, partly vegetarian, indeed omnivorous, in its diet, with lank body, coarse dark hair, long tufted ears, and prehensile tail. There is but one species (*A. binturong*), found in India, Malacca, Sumatra, and Java. It is easily tamed.

Binue. See BENUÉ.

Binyon, LAURENCE, born at Lancaster, August 10, 1869, entered (1893) the British Museum, where he became assistant-keeper. His culture and scholarship are revealed in his poems (*London Visions, Auguries, &c.*), plays (*Paris and Enone, Attila*), and art criticism.

Biobio, the largest river of Chile, has a west-north-westerly course of about 220 miles, from near the volcano of Antuco in the Andes to Concepción (where it is bridged) on the Pacific Ocean. It is 2 miles wide at its mouth, and navigable for 100 miles.—Biobio province (area, 5300 sq. m.; pop. 100,000) lies inland. The capital is Los Angeles (pop. 8000).

Biochemistry. See ANIMAL CHEMISTRY.

Biogen'esis, as opposed to Abiogenesis (q.v.), is the name used by Huxley for the theory that living matter always arises by the agency of pre-existing living matter. See also LIFE, SPONTANEOUS GENERATION.

Biography is the artistic representation in continuous narrative of the life and character of a particular individual. It may be either a mere *curriculum vitæ*, detailing only the historical sequence of the incidents of a man's life, or it may be an attempt at an analysis of his character, opinions, works, and at a complete reconstruction of the motives of his actions. To the former class the ancient examples of biography, as the *Lives* of Cornelius Nepos, mainly belong, while modern biographers have mostly aimed at the latter method. But of course the inward life is revealed in the outward, and even such a biography as the *Agricola* of Tacitus, with all its stately dignity and reticence, does give the reader some real insight into the character of the man. The main object of biography as now written is portraiture, and its success or failure mainly depends on the degree of truth and completeness with which the image is represented. The facts of a life may be fully and truthfully told without any adequate idea being given of the personality of the central figure, which is often revealed in small details that might well escape the notice of a biographer who lacked the eye to see them and their significance. Thus, as Dr Johnson points out, Sallust has not forgotten in his account of Catiline to remark that his walk was now quick and again slow, as an indication of a mind revolving with violent commotion. But indeed it could not be better put than it is by Plutarch, the prince of ancient biographers, in his 'Alexander,' in a passage aptly quoted by Boswell: 'Nor is it always in the most distinguished achievement that men's virtues or vices may be best discerned; but very often an action of small note, a short saying, or a jest, shall distinguish a person's real character more than the greatest sieges or the most important battles.'

It is hardly necessary to add that there is no more interesting department of literature than biography, that the most fascinating study of mankind has ever been and will ever be man himself, and this hardly less in the lyric or the occasional essay than in the formal biography or autobiography. 'I never look,' says Montaigne, 'upon an author, be they such as write of virtue and of actions, but I curiously endeavour to find out what he was himself.' The genuine lyric is a spontaneous and impassioned expression of an emotion of the writer, and its poetical value depends ultimately on the poverty or richness of his personality; while the essay, as understood by Montaigne, its inventor, and such masters in this form as Addison and Charles Lamb, owes no small part of its charm to the pleasing egotism by which hints as to the feelings and foibles of the writer are conveyed by the way to the sympathetic reader. Biography is commonly used as an introduction and key to the works of poets, prose-writers, composers, and other creative artists, the life being illustrated by the works, and the works interpreted in the light of the life.

Many lives (e.g. Lady Burton's biography of Sir Richard Burton) are written in such eulogistic terms that they fall by default to give a truthful picture of their subject, while others, in their fear of being unlike life, deepen the shadows until the picture becomes equally untrue through its over-truthfulness. When rhetoric and adulation obscure or violate the truth, as in so many funeral orations and pious tributes to lives still in progress or newly terminated, biography becomes idle panegyric. *Hagiography*, the branch of biography concerned with the lives of saints, is naturally prone to this tendency, which marks most of the earliest British biographies, such as Adamnan's *Life of St Columba*. On the other hand, many critics accused Froide of having given such undue prominence to the dis-

agreements between Carlyle and his wife as to distort completely the picture of the ordinary life of the pair; while Froude's defenders urged that he had but painted Carlyle as Carlyle would have painted himself, every wrinkle on the face truthfully represented on the canvas, and that his business was to describe the man as he lived, not as he should have lived. Again, a biographer may not understand the relative significance of things, and thus unconsciously give an untrue picture of his subject. Especially is this danger close to him when he has to deal with a time or a society in which he himself has not lived. It is difficult for him to breathe freely in another atmosphere than his own, and avoid anachronisms in feeling if not in fact. Hence the peculiar value of biographical studies by recognised authorities on the period involved, as, for instance, Austin Dobson's 18th century monographs. 'Tell me the company you keep,' says a French proverb, 'and I will tell you who you are.' On this principle some biographers devote special attention to the associates of the person whose life they record, and surround the portrait of their subject with a frame of friendships; in *Charlotte Brontë and her Circle* (1896) Clement Shorter claims to have set a fashion of this kind.

A biographer must have an adequate knowledge of his subject and his surroundings. He must follow him in his controversies and his speculations, and must be able to weigh in the balance his abilities as well as his private virtues. Thus the best biography should be that written by one almost as great as his hero, skilled in the same things, with full sympathy and perfect knowledge, as the life of Dr Arnold by Dean Stanley, and Boccaccio's life of Dante—'a great man,' says Emerson, 'to describe a greater;' while the worst should be the production of the professional biographer, who is ready at a moment's notice to write to order lives of poet, philanthropist, or scientist alike. Boswell, however, was not nearly so great as his hero, though he had insight enough to write the best biography in the English language; while, from a merely literary point of view, some of the most effective biographies we possess were written by men of letters, lacking the special technical knowledge that might have been deemed necessary. Southey's life of Nelson is admittedly one of the most perfect biographies in existence, yet the author tells us that he had to move among the naval terms like a cat among crockery. Indeed adequate insight and sympathy, with a fine sense for literary form, may make up a complete equipment for a biographer, for Walton's lives are absolutely perfect examples of biography, though the garrulous old angler could scarcely have understood the full significance of the great work of Hooker. There are few books in English of such abiding interest and excellence as Johnson's *Lives of the Poets*—a singularly happy combination of sympathy and intelligence, although at the same time a collection of lives of very unequal values. No less admirable are Macaulay's short lives of Johnson, Goldsmith, Atterbury, and Bunyan, written for the *Encyclopædia Britannica*; and Scott's shrewdly sensible lives of Swift, Dryden, Richardson, Fielding, Smollett, Goldsmith, Johnson, and others. Lockhart's *Scott* is generally, and with good cause, ranked next to Boswell's *Johnson* among English biographies.

Most modern biographies are too large—they err by not selecting merely the significant. Perhaps it is true that near things look too large, and that the right perspective is only possible to the observer at some distance. The lives of the greatest men must teem with details that are quite ordinary and unimportant, and we gain absolutely nothing by

having these set down. The biographer must be more than the mere realist who can photograph facts—he must be something of the idealist as well, for he has to create as well as reproduce; and we value a biography exactly in proportion as its author has succeeded in creating for us the character of a new man or woman to be added to our personal acquaintance. If, as has been said, every man's life is worth telling for something that there was in it of unique interest, it may be equally true that all the life save this particular part was not worth telling at all, and had better been left untold. Although undoctored human nature with its swarm of struggling and contending motives is always an interesting study—in its morbid no less than its normal phases—yet the elaborate dissection of mere human frailty must ever be a wearisome and unprofitable pursuit. Man's spiritual aspirations cannot be fed upon mere clever character-analysis, and lives that had in them nothing high for humanity had better be soon forgotten. Some lives are so long, so eventful, so documented, as to defy satisfactory concise treatment, with the result that students now tend to elaborate this, that, or the other chapter of such a crowded career (cf. Lord Rosebery's *Napoleon: The Last Phase*) rather than attempt to deal with it as a whole. In like manner modern literary biographers often confine themselves to the formative period of a great writer's life. Émile Legouis's *The Early Life of Wordsworth* (1897) is one of numerous studies of genius in its youth. Other biographers, again, finding their subject's actual lifetime insufficient for their purpose, dwell at length on prenatal influences and events—taking as long to get their hero born as Sterne takes to bring Tristram Shandy into the world—or expatiate on his legacy to mankind and his posthumous reputation. In the first volume of his life of Francis Galton, Karl Pearson with unprecedented and appropriate scientific thoroughness examines the ancestry of the author of *Hereditary Genius*.

The lives of the great men who have helped to mould their times throw much light on contemporary history. The biographies of Cromwell, Frederick the Great, and Napoleon, broadly speaking, sum up great part of the public history of their times, but do no more for us than merely throw a side-light on its social history, which must be reconstructed by a wide and patient study of the conditions of life of the common people. Masson's life of Milton, despite its ponderous learning and great accuracy, cannot be regarded as a model biography, overweighted as it is with an enormous mass of detail about contemporaries unjustified by anything but a roundabout and indirect connection with Milton himself, who, spite of his poetical and even political importance, was not by any means the centre of the destinies of England. Carlyle's life of John Sterling, again, is an example of an almost perfect biography, and yet it is that of a man whose life was in some respects hardly worth writing at all. He was indeed a man of high aspirations and clear intellect, but beyond this there was scarcely anything very memorable in him, and the abiding charm of the book is due to nothing but the consummate art of the writer and his revelation of himself in sympathy with his subject. Cross's life of George Eliot errs in the opposite direction. Here the biographer adopted the method of making the subject speak entirely by extracts from letters, with the very briefest possible connection of narrative. But by keeping himself so much out of sight, the writer only avoided Scylla to fall into Charybdis, and succeeded in making a book dull and lifeless that should have been unusually full of interest.

So popular a form of literature has biography

become that in the early years of the 20th century from 400 to 500 new Lives were published annually in the United Kingdom alone, including two or three dozen translations from foreign languages. Many biographies, by having a subject of too narrow interest, or by treating a subject in too narrow and special a sense, do not reach the level of a permanent place in literature, though they may have been treated with full knowledge, fine literary sense working within the conditions laid down, and even proper sense of relative proportion. Every year produces examples of biography which are doomed, spite of more or less creditable literary workmanship, to be soon forgotten, from the ephemeral importance to the world of their subjects, and the controversies in which they were involved. Each one, for example, of our hundred religious denominations has its heroes—all important to its own sectaries, but not necessarily of the slightest value to the infinitely wider world. The lives of these men are full of interest within the small circle of their personal influence, but they do not in the least touch the sympathies of readers outside it, unless they chance at once to be written with more than ordinary literary skill, and to be revelations of figures with dimensions much beyond those of the usual church leader or pulpit orator. But unfortunately the hero of our religious biographies is not always a Wesley, a Chalmers, an Edward Irving, a Whitefield, or a Pusey, any more than the biographer is always a Southey, a Hanna, a Mrs Oliphant, or a Liddon. Similarly, there is hardly an eminent man of science, actor, musician, writer, statesman, millionaire, or soldier whose life is not written (often in his own lifetime) at more or less extravagant length, and with a more or less absurd overestimate of his relative importance.

We have many lives, moreover, of very great inherent importance indeed, which appeal to comparatively small circles of readers from the large demand they make upon the possession of special culture or knowledge. Such are many of our larger lives of philosophers, artists, and musicians. Crowe and Cavalcaselle's lives of *Raphael* and *Titian*, Spitta's *Bach*, Jahn's *Mozart*, Karasowski's *Chopin*, and Woltmann's *Hans Holbein* are excellent examples of solid, conscientious, and exhaustive biography, but of too large proportions for the mere literary student.

All history is full of the materials of biography, though it is only in the narrowest sense true that history is nothing but an aggregation of the biographies of individuals. Not a little of the interest in ancient and modern histories alike depends on the pictures of men and women with which their pages are lighted up, and this we find in annalists like Livy and Tacitus, no less than in professed biographers like Plutarch and Suetonius. Perhaps no more living portraits were ever painted than those sketched in a few touches in the lurid colours of Tacitus. In the hastiest sketch of the master we see far more than in the most finished painting by the dauber. Such books as Holinshed's *Chronicle*, Clarendon's *History of the Rebellion*, Burnet's *History of his Own Time*, and Shakespeare's historical plays, from the portraits of individuals they contain, have an additional interest that is only second to their historical importance. Indeed it is far more than a paradox to say that such works of creative fiction as the last are truer than the records of history themselves, for they are informed with a deeper inwardness than these, and do far more to create for us the actual living objective figures of history. Shakespeare's Richard III. is not only a magnificent creation as the dramatic revelation of a matchless usurper, but it is so true a realisation of this working on a sound basis of consistent tradition that it satisfies,

as Mr Gaidner tells us, the requirements of historical truth almost as much as any formal history. Shakespeare's historical figures are not puppets dressed in old clothes, but living and breathing men and women, and the bare historical details of their characters and lives have become fused in his glowing imagination and harmonised into consistent wholes stamped with the warm and actual impress of very truth. This is hardly less true of Macaulay's *History*, and still more of Carlyle's *French Revolution*, with its vivid portraits of even the minor figures flashed like instantaneous photographs upon the reader's brain. Again, books like Spence's *Anecdotes*, Disraeli's *Calamities of Authors and Quarrels of Authors*, are full of rich material for the biographer, as are also such critical essays as those of Macaulay and Carlyle, hardly less than professedly biographic studies like Hayward's *Sketches of Eminent Statesmen and Writers*, and Bagehot's *Biographical Studies*.

One word must be said on the question of the biographer's reticence. Voltaire said, 'We owe consideration to the living; to the dead we owe only truth.' Doubtless this is true if the dead have slumbered long enough to be regarded somewhat impersonally even by their own descendants. But no language is too strong to reprobate the conduct of those writers of biography or autobiography who ruthlessly tear open unhealed wounds and bridge their malice across the separating grave. The concluding and posthumous volume of Campbell's *Lives of the Chancellors*, containing the lives of Brougham and Lyndhurst, is an example of biography, whether due to deliberate malice or no, full of misrepresentation and inaccuracy, to say nothing of lack of generosity and good taste in treating the life of great living contemporaries. Political or religious bias often affects the biographers of great statesmen and churchmen; and the life of a Napoleon, a Mary Stuart, a Cromwell, or a Claverhouse may be strangely distorted by devotees and iconoclasts.

Standard and other biographies of the more important persons dealt with in this Encyclopædia are mentioned at the end of the articles in question, as also in the concise *Chambers's Biographical Dictionary*. 'Authorised' lives of the great are now commonly issued, the biographer being chosen and aided by the subject of the biography, his trustees or family. Thackeray, among others, refused to sanction an authorised life. Some of the best English biographies have been already named; others are Moore's *Byron*; Morley's *Diderot* and *Rousseau* and *Gladstone*; Trevelyan's *Macaulay* and *Fox*; Sir Theodore Martin's *The Prince Consort*; Carlyle's *Frederick the Great*, his *Schiller*, and his *Letters and Speeches of Oliver Cromwell*; Stopford Brooke's *Robertson of Brighton*; Coxe's *Marlborough*; Lewes's *Goethe*; Talfourd's *Lamb*; Mrs Gilchrist's *Blake*; Mrs Gaskell's *Charlotte Brontë*; Washington Irving's *Columbus*; Sparks's *Washington*; Hayley's *Cowper*; McCre's *Knox* and *Andrew Melville*; Lytton's life by his son and grandson; Spedding's *Bacon*; Hamerton's *Turner*; Mark Pattison's *Casaubon*; Helps's *Cortes*, and his *Pizarro*; Froude's *Erasmus*; Forster's *Goldsmith*, *Landor*, and *Dickens*; Maurice, by his son; *Longfellow*, by his brother; Seeley's *Stein*; Dowden's *Shelley*; Cabot's *Emerson*; J. Dykes Campbell's *Coleridge*; Lord Wolseley's *Marlborough*; Henry James's *W. W. Story*; Holland Rose's *Pitt*; Sir Sidney Lee's *Shakespeare*; Monypenny and Buckle's *Beaconsfield*; Lord Randolph Churchill's life by his son Winston; Wilfrid Ward's *Newman*. Remarkable short biographies are More's *Henry VII.*, Cavendish's *Life of Walsley*, Mrs Hutchinson's *Memoirs* of her husband, and *Crabbe's Life*, by his son.

In the French and German languages there are many excellent examples of biography. Here it may be enough to mention the names of some authors whose biographical works are among the most valuable: In France, Flécher, Fontenelle, Voltaire, Boissy d'Anglas, Villemain, Cousin; and in Germany, Schröckh, Herder, Klein, Meissner, Heeren, Liden, Varnhagen von Ense, Barthold, Döring, Pertz, Haym, Arneth, Otto Jahn, Chrysander, Kapp, and Droysen. Dilthey's *Schleiermacher*, Haym's *Hegel*, and Nippold's *Rothe* may also be named. Some excellent biographies that have been translated into English are Köstlin's *Luther*, Zeller's *Strauss*, Loménie's *Beaumarchais*, Düntzer's *Goethe*, Schiller, and Lessing.

Autobiography.—No form of composition is of more abiding interest than that in which a man narrates his own history, unlocks his heart, and takes the public into confidence by laying bare the motives of his life. To know one's self was the first and last step to wisdom, according to the Greek sage. Dr Johnson thought every man's life could be best written by himself, and doubtless so it could if every man were a Dr Johnson. It is needless to say that nothing can be more difficult than to preserve the just balance between due modesty and overweening self-consciousness and self-esteem. In this form there are no better examples in the English tongue than those of Gibbon and Hume, and the opening sentence of the latter is memorable as a canon of art: 'It is difficult for a man to speak long of himself without vanity, therefore I shall be short.' It would be invidious to name autobiographies which reveal a complete overestimate of the writer's own abilities or importance, though our contemporary literature is by no means barren of such books, often naive and unconscious to a degree.

Baber, the Great Mogul, who died in 1530, has been called the Prince of Autobiographers. Autobiographies of more than ordinary value are those of Lord Herbert of Chesham, Sir Kenelm Digby, Jerome Cardan, Ellwood, Clarendon, 'Jupiter' Carlyle, Thomas Boston, Franklin, Haydon, Talleyrand, O. W. Holmes, Harriet Martineau, Béranger, Miss Mitford, Mary Somerville, Hugh Miller ('*My Schools and Schoolmasters*'), Meadows Taylor, Hans Christian Andersen, Leigh Hunt, Berlioz, Macready, John Stuart Mill, George Sand, Mark Pattison, Anthony Trollope, Alphonse Daudet in *Trente Ans de Paris*, Sir Henry Taylor, John Ruskin in *Proteritica*, and the fragment in Carlyle's *Reminiscences*, with its strange sad story of self-reproach lightened up with rare literary charm and gleams of tenderness that make it unique in English literature; Vambéry, Bismarck, Wagner, Kropotkin, Rochefort, Bebel, Roosevelt, Haeckel, Russell Wallace. Among those who, like Renan, have recalled the fascinating story of their childhood and youth are Gorki, Brandes, Edmund Gosse (in *Father and Son*), Helen Keller, and Henry James (in *A Small Boy and Others*).

St Augustine's *Confessions* stands by itself as a revelation of the spiritual history of perhaps the greatest intellect that has ever been entirely mastered and moulded by religion. Completely different in most respects, but hardly less valuable as a confession of the strange spiritual history of a mighty intellect and a great heart, is the *Apologia* of Cardinal Newman. Sir Thomas Browne's *Religio Medici* has high value as a confession of faith, but not a little of its exceptional literary charm depends upon the pleasing egotism with which its author reveals his foibles to the reader. The *Grace Abounding* of Bunyan is a spiritual autobiography of singular intensity, in spite of itself of high value as literature. Rousseau's *Confessions* is a book of rare interest, but hardly of such precious value as

its author imagined, for the ear of the modern reader never fails to detect the ring of the counterfeit that deprives it of half its charm by robbing it of reality. Goethe's *Dichtung und Wahrheit* stands quite alone as the self-told history of the artistic growth of perhaps the best-cultured intellect that the world has ever seen; but its value would be greater if, to use the author's own antithesis, we knew quite how much is truth and how much is poetry. Borrow's *Lavengro* is a book difficult to class, but is substantially an autobiography at least; and the same is equally true of De Quincey's *Confessions of an Opium Eater*, one of the strangest books in our language. Some of our greatest novels contain autobiography wrapped up more or less obscurely in them, and to the consequent reality may owe no little of their power. We know that the story of *David Copperfield* closely follows the early life of Dickens, and that George Eliot herself was just such a girl as Maggie Tulliver in *The Mill on the Floss*. Sterne frequently blends autobiography with fiction; so, too, does Anatole France. There are other books about which it is doubtful how far they are fact and how far fiction, as the *Memoirs of Captain Carleton*. Defoe's *Memoirs of a Cavalier* might well have been true, and the great Chatham did no wrong to his intelligence in accepting it as actual history. On the other hand, such amazing yet genuine records of scoundrelism frankly owned as Benvenuto Cellini's Autobiography and Casanova's *Memoirs* might excusably be classed with picaresque novels of the type of *Gil Blas* or Thackeray's *Barry Lyndon*. Indeed, as a form of literature, the novel, whether romantic or realistic, is (like the drama and the epic) more or less fictitious biography or—when the story is told in the first person in order to appear more vivid and veracious—autobiography.

The letters of Cicero, Madame de Sévigné, Pope, Gray, Cowper, Lamb, and such masters in this form teem with invaluable autobiographical details; and indeed most modern biographies are largely made up of the letters of the subject, and thus are to a great extent autobiographic in character; while many important biographies, as those of Scott by Lockhart, General Grant by his family, and Charles Darwin by his son, contain an autobiographical portion, and so belong to both divisions at once. Much autobiographical and biographical material is also found in diaries, journals, and memoirs written with or without a view to publication. Through such intimate records Pepys, Evelyn, George Fox, Lady Fanshawe, Swift, Madame D'Arbly, Wesley, Horace Walpole, Sir Walter Scott, Crabb Robinson, Senior, Greville, Queen Victoria—to mention only a few—give us inestimable information regarding themselves and their contemporaries. The works of travellers, administrators, soldiers, and social reformers are, as a rule, stocked with autobiographical matter. French literature is particularly rich in *Mémoires*, those of the Comte de Grammont and of the Duc de Saint-Simon being among the most famous. The *Journal* of Marie Bashkirtseff is a masterpiece of self-revelation.

Among biographical works, some are universal, as Michaud's *Biographie Universelle* (1811-28; new ed. 45 vols. 1842-65); the *English Cyclopædia*, biographical section (1856-57); *Nouvelle Biographie Générale* (46 vols. 1857-66); among older books, Bayle's *Dictionnaire Historique et Critique* (1697); Chalmers's *Biographical Dictionary* (32 vols.; new ed. 1812-17); and for our own contemporaries: Vapereau's *Dictionnaire Universel des Contemporains* (6th ed. 1892); the *Dizionario Biografico di Gubernatis* (1880); *Men of the Time* (15th ed. 1899); and *Celebrities of the Century* (1887). Of certain classes only are Vasari's *Lives of Painters, Sculptors, and Architects*; Mrs Jameson's *Memoirs of Early Italian Painters*; Cunningham's *Lives of the most Eminent British Painters*;

Doran's *Their Majesties' Servants*; Bettany's *Eminent Doctors*; Lord Campbell's *Lives of the Lord Chancellors*, and *Lives of the Chief Justices*; Dean Hook's *Lives of the Archbishops of Canterbury*; Dr Smith and Dr Wace's *Dictionary of Christian Biography*; Agnes Strickland's *Lives of the Queens of England*, of the *Tudor Princesses*, and of the *Last Four Princesses of the House of Stuart*, the *Acta Sanctorum* of the Bollandists; Johnson's *Lives of the Poets* (1781); Smiles's *Lives of the Engineers*, and *Industrial Biographies*; Grove's *Dictionary of Musicians* (1879-85; new ed. 1904-10); Muller's *Biographisches Künstler-Lexicon der Gegenwart* (1882). Others again are for certain countries only, as Fuller's *Worthies of England* (1662); *Biographia Britannica* (1747; new ed., unfinished by Kippis, q.v., in 1778-93); Chambers's *Dictionary of Eminent Scotsmen* (1835); Sparks's *American Biography* (1834), and Appleton's *Cyclopædia of American Biography*, edited by J. Grant Wilson and John Fiske (6 vols. 1887-88); and our own *Dictionary of National Biography*, which was edited by Sir Leslie Stephen from 1885 to 1891, and completed (63 vols., with 6 vols. of supplement, index, and epitome) in 1912 by Sir Sidney Lee. There are similar works for France, Italy, Germany, Austria, Belgium, Denmark, Sweden, &c.

Special groups of books that are at once biographies and critical studies are the 'English Men of Letters' series, 'Les Grands Écrivains Français,' and 'Écrivains Étrangers.' In the first, Leslie Stephen's *Johnson*, Dean Churell's *Spenser*, Mark Pattison's *Milton*, Lord Morley's *Burke*, Canon Ainger's *Lamb*, and Sidney Colvin's *Keats* were permanent gains to English literature; the second series opened well with Jules Simon's *Cousin*, Albert Sorel's *Montesquieu*, Gaston Boissier's *Madame De Sévigné*, and E. Caro's *George Sand*; the third includes Legouis's *Chaucer*. The 'American Men of Letters' series contains good studies on *Hawthorne* by J. R. Lowell, *Washington Irving* by O. D. Warner, and *Emerson* by O. W. Holmes; the 'American Statesmen,' lives of *Jefferson* by John F. Morse, and *Adams* by James T. Hosmer. A similar series is that of the 'English Worthies,' edited by Andrew Lang, containing books so good as *Darwin* by Grant Allen, *Marlborough* by Saintsbury, *Raleigh* by Gosse, and *Steele* by Austin Dobson. Other series depending largely on the biographical interest are 'The Great Musicians,' among them *Weber* by Sir Julius Benedict, and *Wagner* by Hueffer; the 'Great Artists,' with *Durer* and *Titian* by Heath, *Hoyarth* by Dobson, *Turner* by Monkhouse, and *Velasquez* by Stowe; the 'Eminent Women' series, with *Maria Edgeworth* by Helen Zimmern, *Mary Lamb* by Annie Gilchrist, and the *Countess of Albany* by Vernon Lee; 'English Philosophers,' with *Bacon* by Fowler, and *J. S. Mill* by Helen Taylor; and the 'New Plutarch,' with *Coligny* by Walter Besant, *Franklin* by Beesly, *Victor Emmanuel* by Dicey, *Abraham Lincoln* by Leland, and *Haroun Alraschid* by Palmer. Somewhat similar, and indeed the earliest of such series as these, are 'Ancient Classics for English Readers,' including literary studies with a biographical setting of *Horace*, *Cicero*, *Xenophon*, *Plato*, *Aristotle*, &c.; and 'Foreign Classics for English Readers,' including similar books devoted to *Rabelais*, *Voltaire*, *Goethe*, *Pascal*, *Diderot*, &c. The 'Philosophical Classics' include monographs so masterly as *Hegel* by Edward Caird, *Berkeley* by Campbell Fraser, and *Vico* by Robert Flint. The 'Twelve English Statesmen' included Freeman's *William the Conqueror* and Lord Rosebery's *Pitt*. Other series are 'Leaders of Religion,' 'Rulers of India,' 'Heroes of the Nations,' 'The Queen's Prime Ministers,' and 'Contemporary Writers.' See LETTERS.

Biology (Gr. *bios*, 'life'; *logos*, 'discourse'). This term has been occasionally abused in English popular writing, more especially in the absurd word *electro-biology*, which at one time threatened to take root in popular usage (see ANIMAL MAGNETISM), and has even by some scientific writers been confused with general physiology, or a special province of it. Yet the established and only legitimate meaning of biology is its literal one, that of the science of life—i.e. the science which seeks to classify and generalise the vast and varied multitude of phenomena presented by and peculiar to the living world. In the following outline the science and its general relations may be conveniently discussed under seven heads.

1. *Origin and Rise of Biology.*—Science being simply a systematised development of our common experience, it is with no more than that simplest knowledge of living beings possessed by the savage or the child that the future biologist sets out. These already keenly observe the forms of life around them: the sheep and goat, the dog and cat, the fowl and sparrow, the trout and salmon, are all clearly recognised and named; and similarly with plants. Classification, too, naturally arises; the birds, beasts, and fishes become more and more clearly defined; and even the residual mob of 'creeping things' discloses possibilities of orderly arrangement. Cedar and oak obtain the common name of trees, briar and bramble of bushes, balm and hyssop of herbs; but beyond this level it is not easy to pass. He is therefore 'the best botanist who knows most plants,' the greatest naturalist who can recognise the appearance and recall the names of the greatest number of living things, or at anyrate can remember most about each of them. This fundamental but as yet scarcely scientific knowledge comes to be recorded in a literature of natural history which varies indeed in accuracy and fullness, yet remains unchanged in spirit and purpose, whether we open the pages of Pliny, Gesner, or Buffon. White's *Natural History of Selborne* may be taken as the classic English example of this nascent phase of biology; and its wide acceptance is not hard to understand, since at this level of simple but comprehensive interest in living beings, every one is by nature, however unconsciously, something of a biologist. But the habit of observation insensibly develops an increased perception of likenesses and differences; collections too arise; the power and need of classification develop and cultivate each other beyond the popular level, and a community of naturalists is thus insensibly formed. These divide, in the first place, into zoologists and botanists, among whom minor circles of specialists occupied with definite groups appear in turn. While this division of labour is apparent, its result is always giving us more and more definite general ideas of the groups studied, and this process of generalisation is summed up from time to time by a mind which unites the old breadth of interest with the newer depth of knowledge. Classifications are continually approximating towards completeness; our masses of knowledge respecting the plant and the animal world are at last brought together as botany and zoology, and the final advance is made through seeking to unite the generalisations of the two. Just as ostrich and swallow, shark and salmon, become united into the common logical genera of bird or fish, so inevitably do plant and animal become united into the general conception of *organism*. Their details of habit and processes of life come to be viewed in general terms of *environment* and *function*. Unity becomes more and more discerned under the manifold variety of these, and the conception of a united and general biology at last lies clear before us. It is, in fact, with the naturalist as with the chemist or mineralogist: the latter has his interest at first awakened by the variety of glistening stones, but soon finds himself eager to interpret and systematise the actual varieties of crystalline form in terms of a few simple ideal ones, with modifications in relation to particular circumstances; while the former passes from the empirical description of the experimental details of the science to the interpretation of these by reference to the properties of chemical elements and the laws of their molecular interaction and arrangement. Similarly, the naturalist passes from empirically recording his observations of living nature or the treasuring of its defunct spoils, to analyse and unify the general problems of life; and thus becomes a biologist proper. It may be well.

clearly to sum this historical advance diagrammatically :

From this diagram the striking contrast, yet continuous gradation, between two such familiar classics as White's *Selborne* and Spencer's *Principles of Biology* may be clearly understood, and by tracing the steps of its correction and development (see BOTANY and ZOOLOGY), the history of scientific advance might be recorded, and even the field of each investigator marked out. Since these details will be outlined under BOTANY and ZOOLOGY, it suffices here to point out that progress has lain in continuously uniting these extremes, so that the crude empiricism which at first absorbed the more concrete students, and the vague and useless metaphysics which were wont to discredit the abstract ones, are being steadily replaced by a compact body of generalisation, along which the specialist at any point may safely ascend to the widest theories of the science, and by which the most abstract thinker may similarly return to lay clear hold of the minutest details of any order of empirical fact. Hence we can clearly understand the way in which the conception of biology was actually first formulated at the beginning of the century, independently and simultaneously by Lamarck and Treviranus (1802); the former rising from his early botanical studies and his *Histoire Naturelle des Animaux sans Vertèbres* to the elevated conceptions of his *Philosophie Zoologique*, which reached general principles as the outcome of detailed studies; while the more abstract mind of the German Treviranus occupied itself with details essentially as interpreted by the help of general principles.

The conception of biology, it will be noted, has thus come to be used with two different contents: in speaking of the principles of biology, we refer to the body of generalisations common to plants and animals; while in speaking of the science of biology, we include the entire body of botany and zoology, with all their concrete sub-sciences. Yet there is here no discord, and we may conveniently accept the definition of Charles Robin: 'Biology is the science which has for its object the study of organic beings, and for its end the knowledge of the laws of their organisation and activity.'

2. *Subordinate Provinces of Biology.*—The results of this natural history study of plants and animals, which seeks above all things to know the actual forms of life, are of course in the first place to be sought in the numerous separate articles devoted to particular animals and plants; next, in the articles devoted to separate families, natural orders, classes, and sub-kingdoms, and finally under BOTANY and ZOOLOGY; while the facts relating to their distribution upon the earth's surface, in present and in past time, are outlined under GEOGRAPHICAL DISTRIBUTION and PALEONTOLOGY respectively. Underlying this empirical view of plants and animals, yet essential to the classification which can alone give this any intelligibility or completeness, lies a detailed analysis of each of these multitudinous forms, which we call *anatomy*. This involves comparison, and *comparative anatomy* arises; but as we come to discern the marvellous unity of type which underlies all apparent differences, and as we (e.g.)

decompose all flowers into variously arranged leaf-whorls, or fancy that we can reduce all skulls to vertebræ, or again analyse the organism into organ, tissue, or cell, the conception arises of what was at first called transcendental or philosophical anatomy, but which later became known as *morphology*. This term has also been extended, and on the whole with advantage, to include not only these widest generalisations of unity in organic forms, but all the details as well, in fact all the *static* aspects of organisms as distinguished from their *dynamic* or vital ones, which we similarly group under *physiology*. In the same way the crystallographer is, as it were, the pure morphologist, but with him we can scarcely avoid including the descriptive mineralogist as well.

But while the morphologist deals primarily with the anatomical facts presented by the organism before him at a given moment, he can only fully understand the origin of these and still more their resemblances and differences by reference to its form at earlier and earlier past times; and in the endeavour to reach this fuller conception of form no longer viewed at rest, but as a result and phase of change, we constitute the sub-science of *embryology*. See ANATOMY, MORPHOLOGY, EMBRYOLOGY.

Yet our biological studies are even now not biological in the most literal sense, for the study of mere forms can take no note of the life which possessed or produced them. The morphologist's dealings are with fossil and corpse; his botanic garden is a herbarium, his appliances the scalpel and lens; whereas it is the harder task of his physiological colleague, instead of simply describing the machinery of life, to comprehend it in action. He thus of course requires an acquaintance with the results of the study of forms, but only for the sake of applying, and if possible interpreting these. In a word, his problems are no longer those of statics, but of dynamics. These dynamic or physiological problems in the first place concern the individual organism at a given time both as a whole and analysed; we study its internal and external relations—its respiration and nutrition in all cases, its sensation and movement if such there be. But the conception of phases of function at successive times necessarily also presents itself; and the more complex problems of growth and adaptation, of variation and of disease, thus arise: while when we pass from the study of the organism alone to its relations to the species, the processes of reproduction and the marvels of heredity appear for elucidation (see ENVIRONMENT, HEREDITY, PATHOLOGY, PHYSIOLOGY, REPRODUCTION, VARIATION). And in all these cases, as we shall see below, these problems may be attacked at different levels—i.e. in terms of organ, tissue, cell, or protoplasm.

3. *History of Morphology and Physiology.*—The progress of our concrete knowledge of plants and animals is respectively outlined under BOTANY and ZOOLOGY, and even from these articles it will be sufficiently obvious that these two developments are not mere isolated streams of discovery, but have a deeper than biographical interest. Our historic inquiry must now seek to fuse these two detailed chronicles of botanical and zoological advance into a broad and general sketch. This should show how the whole development of modern biology, despite its multitudes of past and present workers, and its apparently overpowering wealth and variety of detail, lies upon a few essential lines of investigation, which have been opened up by a magistral succession of original thinkers, and simply extended and elaborated by their respective schools. For were this grasp of general principle once obtained, it is evident that we should be in

possession, not merely of an additional fragment of more or less interesting historical information, but of a well-twined and trustworthy clue which should at once guide us through the teeming maze of organic nature, and among the corresponding recesses of the vast and increasing library of biologic science.

(a) *Morphology*.—Starting then from those chaotic accumulations of fact and blunder, myth and fancy, of practical usefulness and traditional quackery, which characterise the medieval encyclopædias of natural history, we find their inevitable criticism and replacement at length fairly undertaken in the latter half of the 17th century by the labours of John Ray and his minor contemporaries. Yet the period of general natural history was not to end for a century, for it is in Buffon's wide and brilliant survey of all that was known of animal life—the famous *Histoire Naturelle Générale*—that the ancient school found at once its highest outcome, its monument and grave. The modern period, then, essentially opens with Linnæus, whose importance depends upon his having brought to bear upon the confused accumulations of the past the critical and analytic skill, the accuracy and descriptive power, and the classificatory resources of existing logic, which had hitherto been dragging on a merely academic or at most controversial existence, but left almost devoid of concrete or constructive applications. The importance of the order introduced by his binomial nomenclature, his establishment of the categories of species and genus, order and class, his precision of descriptive terminology and the like, can hardly be overrated; while his definite concentration for classificatory purposes upon the precise form of the organism as distinguished from its mere general appearance and mode of life, laid the basis of the future science of pure morphology. Despite the opposition of Buffon, whose thoroughly synthetic attitude and ardent enthusiasm of living nature were alike naturally repugnant to the cold analysis of the new Linnæan school, this necessarily triumphed, indeed too completely. The orderly and exhaustive catalogue of natural forms begun by Linnæus was ardently taken up by his pupils, and handed on to his innumerable intellectual heirs; and it is still in progress, as every systematic monograph, such as those of the *Challenger Expedition*, still testifies. Each new species described means in fact a new leaf added to his *Systema Nature*, and the original work is thus, as it were, under continual revision and extension by a succession of sectional sub-editors. Yet, although invaluable as an index to the museum of nature, and indispensable as a catalogue for the future library of the science, the preparation of this systematic description of species gradually enslaved its labourers, and blinded them to all the other problems presented by the living beings which came under their notice. But although this disastrous tendency remains even now too common, the required deepening of the science was soon fairly begun by Jussieu, who passed from the description of external forms alone, and the artificial and provisional grouping of species by their superficial characters, to the establishment of large natural alliances upon a basis of comparative anatomy. He thus not only founded the 'natural system' in botany, but suggested to Cuvier that re-examination of the animal world upon similar lines which became his life-work. But this supplementing of superficial description by detailed anatomical and comparative research has not only given us the classic *Règne Animal* of Cuvier, but its continuation by an entire school—the comparative anatomists. Of these Meckel, Muller, and Gegenbaur in Germany, Milne-Edwards and Lacaze-Duthiers in France, Owen and Huxley in

England, will be remembered among the most historic veterans.

The next step, that of penetration below the study of organs, is due to Bichat, who analysed the body into a series of simple tissues—muscular, nervous, glandular, connective, &c., with definite structural characters. Here, then, a new movement—the histological—found its beginning, and thus under Bichat's *Anatomie Générale* we may group not only the labours of his immediate successors, but all those researches on embryonic layers and tissue structure which have of late formed an increasing proportion of recent literature.

Histology had not, however, found in the study of tissues its ultimate basis. The microscopic studies of the botanist Schleiden led him, in 1838, to the conclusion that all plant structures were built up of separate unit-masses or *cells*, a generalisation immediately extended to animal structures by Schwann, who published in the following year his famous *Microscopic Investigations on the Accordance in the Structure and Growth of Plants and Animals*, as the English translation (Sydenham Society, 1847) has it. The tissue being in this way analysed into a cell-aggregate, that elaborate and detailed study of cellular forms and structures, development and modifications, which still mainly occupies the histologist, was thus fairly begun.

Finally, the description of the essential living substance of some of the lowest animal cells by Dujardin, and the similar account of vegetable cell-substance by Von Mohl, have directed attention from the cell to the all-important protoplasm of which it is composed. Here, of course, opens a new series of investigations, in which a basis for the study of organic structure is sought in the investigation of protoplasm. No deeper analysis is possible, without passing out of morphology altogether into chemistry and physics; and we are thus warranted in regarding the preceding five great categories of morphological inquiry as exhaustive, although progress within each of these is still far from ended. It must not be forgotten, indeed, that especially since the establishment of the last two of these categories (cell and protoplasm) we have had a new light cast upon all five through the study of development, with which names like those of Von Baer, Kölliker, and others, are so imperishably associated. Thus we can now trace not only the origin and differentiation of the cell itself, but that of the tissue, the organ, and the organism, from the ovum or primeval cell. Recognising, however, this general indebtedness to the embryologist for elucidating, under the actual facts of being, their mode of *becoming*, we may still classify the labours of morphologists as being essentially continuations of the five fundamental classics above mentioned.

(b) *Physiology*.—The early physiology was a matter of very vague and often mystical interpretation of the processes of the body, as phrases like those of 'animal spirits' and 'vital spirits' still survive to show. At best it was broadly little more than a superficial account of habit and temperament, which, although corresponding to the observation of general form later inaugurated by Linnæus, had yet little of the order and definiteness of this. The progress of anatomical research could not, however, fail to suggest that many vital processes were associated with definite organs or systems of organs, and the analytic study of physiology may be thus regarded as beginning with Harvey's memorable demonstration of the circulation of the blood. The study of the functions of each organ, viewed as a whole, long continued to form the sole problem of physiology. The illustrious Bichat was, however, no less a physiological than a morphological thinker; and in the physiological portion of his

Anatomie Générale, function was referred from the organ as a whole to the fundamental properties of its essential tissue. He thus not only deepened both morphology and physiology by a new analysis, but showed them to coincide; and in this way we come to understand how he so early clearly reached the conception of a unified science of biology.

With the advent of the cell theory, function, which had thus been referred from organ to tissue, had of course next to receive a yet deeper interpretation in terms of the constituent cells of these. Cellular physiology and pathology were clearly foreseen by Goodsir, and soon developed by Virchow and his school. Yet the interpretation of function in relation to structure, which had been successively undertaken at each deepening level, began even at this one to break down. Attention came to be directed to the nature of protoplasm, and physiology, as Foster expresses it, thus began to undergo 'a change of front.' For the physiologist has now to view the problems of function of organ, tissue and cell alike, as outcomes or accompaniments of the destructive and constructive molecular changes (*metabolism*) of its protoplasm, of the physical and chemical processes of its waste and repair, its *katabolism* and *anabolism* respectively. This ultimate school of physiology may be headed by the works of the late illustrious Claude Bernard.

It is a fact of no little significance that these two independently deepened lines of research, morphological and physiological, are accurately parallel, stage for stage; not a little remarkable that the two sub-sciences of morphology and physiology should have independently undergone a precisely similar evolution. The result of our survey may in fact be conveniently illustrated by means of a couple of similar bookcases—one for morphology, the other for physiology—the shelves of each being allotted, in descending order, to the literature of the structural and functional aspects respectively of organism, organ, tissue, cell, and protoplasm, and each shelf being headed by its initial classic. To this biological pentateuch, of morphology and physiology respectively, each set of subsequent researches must be simply regarded as commentary or appendix. For since not qualitatively distinct, the originality of these is simply of a quantitative order. And if we imagine these cases, instead of being placed side by side as in the diagram, to be situated back to back, we have a yet clearer image of the completeness of their parallelism, as well as of the way in which they have independently been filled by workers approaching from quite different sides.

MORPHOLOGICAL	ASPECT OF	PHYSIOLOGICAL
+ Linnæus	Organism.	Hippocrates +
+ Cuvier	Organ.	Harvey +
+ Bichat	Tissue.	Bichat +
+ Schwann	Cell.	Virchow +
+ Dujardin	Protoplasm.	Bernard +

(c) *Evolution*.—Where, however, it may be asked, is the position on such a scheme of the literature of

evolution? The reply of course is, that like the conception of individual development of form and function, that of racial development does not lie upon any one level, but equally below them all. The evolutionist, like the embryologist, of course considers form and function in process of continuous change, while the morphologist or physiologist views them as constant at any given moment. Hence the diagrammatic representation of our evolutionary conceptions would lie in another plane; its literature might indeed be placed on the same shelves, but behind the volumes occupying them. The history of the doctrine of evolution, like that of embryology, may therefore more conveniently be treated separately (see EMBRYOLOGY, EVOLUTION), while the subject of distribution, not being a department of pure biology at all, but rather of geology and physical geography, does not enter into the present discussion (see DISTRIBUTION).

4. *Nature and Origin of Life*.—It is by this time sufficiently clear that the biologist is solely concerned with the positive facts of living nature, and is seeking only verifiable generalisations. He accepts the relativity of all scientific knowledge, and has long been wholly freed from alchemist-like dreams of reaching any 'vital essence' or ultimate secret of life other than that of a classified and unified account of its phenomena. The history of speculation as to the ultimate nature of life may therefore be conveniently relegated to a separate article (see LIFE), in which the various attempts to define it will be found: for actual biological purposes, the life of an organism is simply the sum of its functions, internal and external; nor need any other working conception be desired, if we agree that the ideal of organic life, that of a maximum of healthy function, implies the harmonised yet progressive adaptation of function and environment. Similarly, the history of speculation as to the unknown origin of life is separately discussed (see SPONTANEOUS GENERATION); while such actual knowledge as we possess respecting the structural and functional properties and characteristics of living matter is summarised under PROTOPLASM.

5. *Place of Biology among the Sciences*.—While no special account of the logic of biology is required, save that its study demands 'observation and experiment, comparison, classification, and historic filiation'—in short, all the powers of the scientific intelligence—its relation to other studies is a matter of more serious dispute. The essential problems, briefly stated, are: (1) How far and in what way the phenomena of biology are interpretable by and related to those of chemistry and physics; (2) How physiological phenomena are related to mental ones. The reply which is offered to these questions by many biologists may be best stated in two quotations from Huxley: 'Considered apart from the phenomena of consciousness, the phenomena of life are all dependent upon the working of the same physical and chemical forces as those which are active in the rest of the world. . . . A mass of protoplasm is simply a molecular machine of great complexity, the total results of the working of which, or its vital phenomena, depend on the one hand upon its construction, and on the other upon the energy supplied to it; and to speak of "vitality" as anything but the name of a series of operations, is as if one should talk of the "horology" of a clock.' Again, 'the biological sciences are those which deal with the phenomena of living matter, and though it is customary and convenient to group apart such of these phenomena as are termed mental, and such of them as are exhibited by men in society under the heads of psychology and sociology, yet it must be allowed that no natural boundary separates the subject-matter of the latter

sciences from that of biology. Psychology is inseparably associated with physiology, and the phases of social life exhibited by animals other than man fall strictly within the province of the biologist.'

From these positions the transition is easy to the dogmatic materialism of writers who look forward to completely reducing functional and psychological processes to chemico-physical ones. But it has long been pointed out that the functional states and changes which we call physiological, and the mental states and changes which we know as psychological, have each their own definiteness and continuity. Motions are continuously traceable to antecedent motions, which may be termed their causes; nor is there any hiatus at which 'vitality' or the like can be inserted; similarly, however, changes in mentality are preceded by antecedent changes of mentality; which are equally entitled to be termed their causes. A comparison of the two streams shows indeed a definite parallelism between them; so that we constantly interpret one by the other. Feature, voice, and gesture are thus familiarly regarded as the 'expression' of psychological states, while the physician constantly ascertains the state of function by inquiring into the feelings of the patient. As, moreover, he next verifies this by a physical and chemical diagnosis, we become convinced of a complete constancy or parallelism of normal and pathological relations between chemico-physical changes, organic functions, and psychic states. The materialistic interpretation—i.e. of the latter two in terms of the first—is, however, as Comte has especially insisted, as unverifiable as would be the converse transcendental one. The links of the argument that physical changes set up the mental ones, may with equal strength be placed in precisely reverse order, to prove that psychic changes set up the physical ones. Given in fact these three orders of phenomena, physico-chemical, biological, and psychic, the labours of physiologists have done great service in establishing detailed parallelism between all these processes, yet leave the original distinctness of each category unimpaired. We can not only correlate the digestive process with normal psychic states of hunger and satisfaction, but define its physico-chemical constants, and even experimentally reproduce these in our test-tube outside the organism altogether. In a definite and very important sense, therefore, we can now say that we understand digestion in terms of chemistry and physics; but this advance of our physiological chemistry is apt to produce serious misunderstanding when it prevents the chemist from seeing that his biological colleague is not ultimately concerned with the action of the acids and ferments, in terms of which the chemical 'explanation' of digestion is expressed, but with digestion as one factor of his biological unity, the organism—as one process of its 'life'—i.e. of its adjustment of internal and external relations, a complex process with which no test-tube can present the slightest parity. Similarly, the psychic state accompanying digestion, whatever its precise physico-chemical and functional concomitants (although it is of course most interesting and desirable to define these), is only truly known by reference to the whole succession of phases or forms of mentality, which it is the problem of psychology to analyse and classify. It similarly, therefore, eludes all attempt at expression in terms of the contents of our test-tube, unless, indeed, we go so far as to endow this or its contents with specific mentality as well: this, however, would of course be an unverifiable hypothesis of transcendentalism, not a scientific materialism at all. In short, then, the physiologist is entitled to say that he knows of 'no thought without phosphorus,' but by no means that 'the brain secretes thought as the liver does bile.'

Again, since in sociology our problem is of social aggregates, the study of the individual may and does indeed furnish the most valuable data, but our ultimate sociology—i.e. our generalised and unified science—is concerned not with the individuals but with the essential drama of the race. The final *reductio ad absurdum* of the crudely materialistic position is afforded by pushing it to its logical consequence, for if, as we see many disposed to think, social phenomena fall truly within the province of the biologist, and this be but the interpretation of molecular machinery in terms of chemistry and physics, then the ultimate generalisations of sociology, the philosophy of history, would have to await elucidation by the organic chemist! It will thus be sufficiently clear that the parallelism which we are constantly establishing between all orders of phenomena, physical and biological, biological and psychological, or these and social, and which we may define as the province of a legitimate materialism, in nowise interferes with that claim to the unity and distinctness of each of these sciences, which remains as the stronghold of an equally legitimate transcendentalism.

6. *Generalisations of Biology.*—But while all these provinces of the science must be separately discussed, their results demand unification. It must not be forgotten that science, no less than music, is to be distinguished from its printed records, and even from our power of recollecting its details piecemeal. For the measure of our grasp of biology lies in our power of simultaneous orderly presentment of its whole body of essential truths before our minds, and such a breadth of synthetic vision, although demanding an exceptional effort, is becoming at least partially possible.

If we thus attempt to reach the largest possible general view of the science, we have evidently not only to unite the results of the morphological and physiological study of the organisms before us at the present moment, but to introduce the conception of past, indeed also of future time as well. This entire drama of organic existence is what we have now learned to call its *evolution*; and consequently, since this supreme generalisation has been clearly laid hold of by the students of separate sub-sciences, these have been well-nigh transformed. Their unification and detailed progress have alike made enormous advances, and we are thus rapidly approaching a unified and systematic account of organic nature.

Within the present limits only the merest outline of this synthetic view can be attempted. Starting once more at the rise of modern botany and zoology, we see the naturalists of the renaissance slowly disencumbering themselves of the literature of mere medieval traditions distorted from the classic past, which did duty for natural history, and returning to nature. We watch the rise of the systematic movement from Ray to Linnæus, and thence trace its extending exhaustiveness, aided by new appliances like the deep-sea dredge and the microscope, new facilities like the marine station and the exploring expedition, and carried on by an ever-increasing multitude of workers. Accepting this catalogue of organisms, which, though still incomplete, is now for most purposes far more than adequate, we have next to sum up each of the successive planes of morphological and physiological research, and seize the results of the scrutiny and comparison of the form and function of organs, tissues, cells, and protoplasm of the multitude of organisms which have now been submitted to this detailed analysis. An attempt at the synthetic presentation of this must set out from the Protoplasm (q.v.), which is the 'common denominator' or 'physical basis' of life. Here we have to acquaint ourselves with the conditions of its

existence, and take note of the physiologist's enumeration of its functions as 'contractile, irritable and automatic, receptive and assimilative, metabolic and secretory, respiratory and finally reproductive' (see PROTOPLASM).

The study of the unit-mass of protoplasm or cell should next be summarised, its varied forms surveyed and classified from the simplest to the most complex and many-celled plants and animals, and these generalised into the conception of a simple 'cell-cycle,' ranging between a more or less passive and encysted spheroidal form to a less or more motile (ameboid or elongated) one. The phases of cell form are also seen to arise as so many stages of the rhythm between growth and waste (anabolism and katabolism) into which, as we have seen above, all functions are finally summed (see CELL). The simplest organisms are separate unit-masses of protoplasm, of which the life-history essentially coincides with the cell-cycle aforesaid (see PROTOZOA). In higher but still unicellular forms, the resting or the motile phase becomes more and more permanent and specialised, and a distinctly plant or animal character thus makes its appearance. Multiplication soon becomes habitual at some one definite phase, and instead of the separation of the resultant portions to lead an independent life, we at length have their continued union. Such a union of normally resting cells gives us the multicellular plants or *Metaphytes*; that of normally ameboid cells, the multicellular animals or *Metazoa* (q.v.). By the more passive vegetable organism the energy of the sun's rays is usually absorbed by aid of a green colouring matter (Chlorophyll, q.v.), and applied to the reduction of the carbonic acid of the atmosphere, starch and cellulose being also normal products, while their nitrogenous matter is obtained in solution as ammonia or nitrates. On the other hand, the more active animal is dependent for its nitrogenous food on proteids already directly or indirectly worked up by the agency of plants, and also for its carbonaceous on organic substances, starch, sugar, fat, &c.

Of the multicellular plant or animal only a few cells remain comparatively undifferentiated to form the reproductive elements. In these that alternate or permanent preponderance of katabolism or anabolism, which is a constitutional feature of the adult life of the great majority of living beings, usually specially asserts itself; and we have thus the development of those motile and resting forms which are henceforth respectively characteristic of the male and female 'sex' (ovum and spermatozoon). See REPRODUCTION, SEX. After a more or less distinct 'rejuvenescence' of the primeval cell-cycle, usually accompanied by that complete union with a cell of contrasted sex which we term fertilisation, the resultant cell (fertilised ovum) undergoes segmentation into an embryonic mass (see EMBRYOLOGY). From this a new adult organism gradually develops. In the animal this embryonic sphere becomes dimpled into a two-layered sac, the primeval stomach or 'gastrula'; a third intermediate layer arises, and from these three certain definite organs constantly develop. The outer furnishes the epidermis, nervous system, and sense organs; the inner layer the alimentary canal and its appended glands; and the middle one the skeletal, muscular, excretory, and reproductive systems. This unit of origin gives us a starting-point for identification of like organs in different animals, and the fertile study of *homology* thus begins. Again, this development of at first similar cell-unions into tissues and organs is readily explained as a consequence of the division of labour in the individual and in the race. The associated units have their activities restricted in one way or in another, and their energies find new outlets varying with their special

circumstances. Function establishes structure, and these gradually perfect each other; the *tissue* is thus formed, and by-and-by becomes rounded off or combined with other tissues into a definite mechanism, the *organ*, while these may form a still larger unit, the *system*. It is therefore the development and complexity of this physiological progress of division of labour which determines the special and general form of the organism. We thus see how the results of pure morphology (anatomy without regard to physiology) acquire a rational explanation by reference to the physiological processes which shape organic forms. With increasing complexity of structure we have necessarily an increasing simplicity of function, for the many processes at first crowded into a single cell become, so to speak, sorted out into the different organs. Residual traces of all these protoplasmic properties must, however, remain in varying measure in even the most specialised of living cells, hence the possibility of functional change is never closed, since use, disuse, or changing circumstances may set up a renewed increment of any one or a continued decrement of any other of these minor processes, however apparently suppressed. Here in this latent potency of change we have in short the rationale not only of the cell-cycle with which we set out, but the explanation of the otherwise mysterious phenomena of reversion and progression—in fact, of the occurrence of all variations, normal or pathological alike. See PHYSIOLOGY, PATHOLOGY, VARIATION.

It is clear that this specialisation of organs involves their dependence upon each other, and that if one suffer or develop, this must affect all its partners in the general life. Hence we obtain 'correlated variations,' and interpret the various symptoms of a given disease. Progress as regards organs is thus twofold—(1) in continued development and increased division of labour of the parts (differentiation); (2) in increasing correlation of the parts to each other and in subordination to the whole (integration). And when we note that any higher integration depends upon a preceding new differentiation, which of course disturbs the existing equilibrium of the whole, we are in a position at once to comprehend the beginnings of disease, and to realise that the traditional pessimistic interpretation of this admits of important modification.

A strict classification of the organs is rendered difficult by the varied ways in which different organisms have solved the problems of adaptation: a general correspondence to those essential properties of protoplasm which we noted at the outset is of course observable, since the frog has no functions which were not foreshadowed in the amoeba. The older physiologists, however, clearly pointed out that the primary classification is that which separates the reproductive or species-regarding functions from the remaining individual ones; while the latter are again divisible according as they are concerned with the internal problems of the organism—i.e. with nutrition (also circulation, mechanical support, &c.) or with the external problems of relation to the environment (sensory, nervous, muscular). These fundamental contrasts between reproduction and individual development, and between the vegetative and the animal functions, are in fact the largest physiological features of organic nature, and admit of fruitful application (see VARIATION) to interpret the endless details of plant and animal form and life.

Returning to these, which we are now in a position to view as an ordered whole, we find that (a) the successive appearance of related types upon the globe broadly (and sometimes even minutely) corresponds to (b) the order of increasing complexity established on purely anatomical grounds, while

the embryologist (*c*) finds that the development of the individual from its unicellular simplicity to adult complexity repeats the same essential succession of phases. This threefold coincidence next demands explanation, and the 'theory of descent' from a flora and fauna of increasingly simpler character in the past necessarily makes its appearance; nor has any other scientific explanation been suggested. But this modification during descent next demands explanation; a problem of supreme difficulty which has had many attempted answers.

From all these repeated attempts to discern the principle of organic progress, the naturalist has been learning to change the static or anatomical view of living nature for the dynamic and physiological one—in other words, to rise from the analysis of the individual as a dead specimen to the conception of the species as a living whole. The commanding superiority and wide scientific influence of Darwin among naturalists are of course popularly, though groundlessly, associated with the origin instead of the final popularisation of the conception of descent; while even by scientific men they are frequently assumed to be essentially associated with his particular hypothesis of natural selection as the rationale of progressive modification; yet his biological influence and example primarily depend on his having fairly established in practice this great transition from the pursuit of dispersive specialisms towards attempting a general view and explanation of organic nature. Since his time, our knowledge of the plant can no longer be grouped round the dried herbarium specimen of it, as had been the case since Linnaeus' day. It has become again for us a living being, not only breathing, and growing in the sun, but moving, digesting, sensitive, often in a measure hardly second in its fullness to that of animal life—in a word, the dryad of old poetry has been recalled to life by modern science. The individual, too, has wide relations, here it may be to other plants, here to insects, there to birds and beasts: the entomologist must leave his museum, and the botanist his herbarium, to work out in the garden together the steps by which insect and plant have wrought out each other's form and destiny: they have soon to call in other specialists to their aid; and the world thus comes to be understood as a vast and complex web of life, and its many forms as related to each other by innumerable complex ties. Thus the farmer's cat influences his clover crop, or the distribution of a particular insect determines alike the civilisation and the scenery of vast regions of Central Africa. In this way the unit-problem of the science has become no longer the description of the isolated specimens of its index collections, but the history of the entire species in its living relations, actual and historic. See ECOLOGY.

Since the doctrine of natural selection, which is the more immediate contribution of Darwin and his school to the theory of evolution, will be found summarised under DARWINIAN THEORY, and discussed under EVOLUTION, it suffices here to point out that, despite its wide applicability and indisputable services, its finality is again becoming disputed by various naturalists on different grounds (see EVOLUTION, VARIATION). On one side the older explanations, in terms of use and disuse, environment, &c., are being revived; while on another, it is being attempted to replace the received doctrine of indefinite variation, with progress by means of struggle for existence among individuals, by the conception of definite variation (even pathological), with progress essentially in the measure of the subordination of individual struggle and development to species-maintaining ends, reproductive, domestic, or associative. Without entering into details, it is evident that such a

restatement of the theory of the evolution of living beings—in terms no longer primarily of strength and competition, of hunger and battle, but of love and co-operation, of sacrifice and pain—would involve, no less fully than has the doctrine of struggle for existence, a deepened reinterpretation of plant and animal life, and would similarly extend into other fields than those of pure biology.

7. *Conclusion—Biology and Practical Life.*—While biology as a science finds its source and justification in the natural impulse to contemplate, and reasonable desire to comprehend the world and our place in it, its action and reaction with practical life requires brief consideration. Our knowledge of animals, like the child's, obviously arises with their chase; and that of the aspects and properties of plants, wholesome and poisonous, perhaps even medicinal, with the hungry search for roots and berries. The evolution through higher social states finds its reflection in widening zoological and botanical folklore, and the developed agricultural conditions of civilised life not only admit of the increasing and systematising of our knowledge, but even at length contribute valuable conceptions, like that of selective breeding, of which Darwin has made such especial use. The recent contributions of biology to the arts of life have been of course primarily associated with the advance of medical treatment; hence the popular and even medical conception of the botanist is still based upon the traditional one of the herboriser in quest of specific remedies. The increase of food-supply, through pisciculture and breeding, and through the destruction of the enemies of useful species, is an application of more recent but widening growth; in fact those applications of our knowledge of cryptogamic pests which have especially culminated in the labours of Lister and Pasteur (see GERM THEORY), at present furnish the stock illustration of the applicabilities of pure biology. New ideas are also germinating; thus speculation is busy—e.g. with schemes of artificial human selection; while rapid progress is being made in the transition from detailed medicine to wholesale hygiene—i.e. beyond the mere application of specific remedies to morbid individual variations, and towards a progressive and harmonious reorganisation of the functions and environments which are afforded by the human hive or city to its individuals. For the task of biology applied as hygiene should not only be to subdue the tendencies to morbid variations, but to determine that maximum of optimum life-cycles, which is the biologist's and hygienist's concrete rendering of the greatest happiness of the greatest number. And as the twin scientific motives of childlike curiosity, with its analytic pursuits, and of maturer contemplation, with its synthetic aims, become balanced by the corresponding practical ones of the arts and their application to the general humanist problem just outlined, our biological science and art may be fairly expected to react more and more fully in their associated yet alternate progress.

This hope is indeed confirmed by the whole past history of the science; with a glance at which in its most general aspect the present article may fitly conclude. At the very outset (§§ 1, 3) we saw that biology is no mere isolated stream of fortuitous discovery; next (§ 5), that it is no mere separate discipline which can be exhaustively pursued apart from other sciences; and—now (§ 7), that it has arisen from, and constantly returns to, ordinary life and practice. In tracing the progress of biology, we are simply following the reflection of the changing lights cast upon the organic world by each prevailing mode of general thought and social life. In a word, the evolution of biology forms part of the general social evolution; the science is no

completed body of truth, but merely such portion of it as our stage of social progress enables us to see. Else the rise of science from art would be little more than an almost prehistoric process, instead of being still and continually going on. Innumerable instances, large and small, might be given of this; thus, the classificatory doctrine of the 'échelle des êtres' (see ZOOLOGY) due to the naturalist Bonnet, is far more than a mere detail of the biographical history of zoology; for the conception of an unbroken series of beings ascending in regular gradation from the lowest up to the highest is obviously the projection upon nature of that established ecclesiastical and social hierarchy in which the good abbé's mind was formed. Again, taking a larger instance, the substitution of Darwin for Paley as the chief interpreter of the order of nature is currently regarded as the displacement of an anthropomorphic view by a purely scientific one: a little reflection, however, will show that what has actually happened has been merely the replacement of the anthropomorphism of the 18th century by that of the 19th. For the place vacated by Paley's theological and metaphysical explanation has simply been occupied by that suggested to Darwin and Wallace by Malthus in terms of the prevalent severity of industrial competition, and those phenomena of struggle for existence which the light of contemporary economic theory has enabled us to discern, have thus come to be temporarily exalted into a complete explanation of organic progress.

Finally, the division of labour having become fully established in industrial practice, and recognised in economic theory by Adam Smith, it was frankly borrowed for biological application by Milne-Edwards, almost a couple of generations later, with fruitful results. This industrial development has indeed not only given us our present clear conception of separate organic functions, where an earlier school could see only their general resultant as 'temperament,' but it has also determined the prevalent intensity of scientific specialism within artificially restricted fields. Hence too, the extreme specialist's not infrequent loss, if not indeed denial, of definite responsibility to the science as a whole, and still more to that larger progress of which it forms a part, is simply the equivalent of that loss of conscious relation both to the special task and to its general bearings, from which at present the labourer also so frequently suffers. But as we progress with the synthetic reorganisation and practical application of the science, we may anticipate the recovery of both.

The manifold importance of biology in education is seen not only in its practical applications in the arts and in the study of medicine, but as a potent agency of culture, and as preliminary to psychological and social studies. See BOTANY.

Literature.—See, beside articles mentioned above, LAMARCK, SPENCER, WEISMANN, &c.; also Comte, *Philosophie Positive*; Robin, *La Philos. Pos.*; Lafitte, *Revue Occidentale*, 1; Spencer, *Principles of Biology* (1866); Haeckel, *Générale Morphologie* (1866); Huxley, *Anatomy of Invertebrate Animals* (1878); text-books by J. R. A. Davis (1888), R. J. H. Gibson (1889), T. J. Parker (1891), H. G. Wells (1893); J. Arthur Thomson, *The Science of Life* (1899); Alfred Earl, *The Living Organism* (1899); Räd, *Geschichte der Biologischen Theorien* (1905-9).

Bion, one of the three Greek bucolic poets, was born near Smyrna, but settled in Sicily, where he is said to have been poisoned by a jealous rival—probably a poetical fiction. He imitated his earlier contemporary Theocritus; the author of the 'Lament for Bion' calls himself his pupil. Little of his work has survived save his 'Lament for Adonis.' His works are usually edited and translated with those of Theocritus (q.v.).—BION OF BORYSTHENES flourished about 280 B.C. At first a Scythian slave,

he studied philosophy at Athens, and afterwards lived at the court of Antigonos Gonatas.

Biometrics, the statistical study of living organisms, has thrown much light on Variation and Heredity (q.v.). See *Biometrika*, and writings of Galton, Pearson, Weldon, D'Arcy Thompson.

Biot, JEAN BAPTISTE, a distinguished French physicist and astronomer, born at Paris, April 21, 1774. He entered the artillery, but forsook the service for science, and in 1800 became professor of Physics in the Collège de France. Along with Arago (q.v.), he was (1806) sent to Spain to carry out the measuring of a degree of the meridian, and in 1817 he visited England, and went as far north as the Shetland Islands, in order to make observations along the line of the British arc of meridian. His most valuable contributions to science are on the polarisation of light, for which he received the Rumford gold medal in 1840; his researches into ancient astronomy are also very valuable. Among the latter may be mentioned his *Recherches sur l'Ancienne Astronomie Chinoise* (1840) and *Études sur l'Astronomie Indienne* (1862). His works on physics are still esteemed; the 3d ed. of his *Traité Élémentaire d'Astronomie Physique* (5 vols. 1841-57) was translated into English. In 1849 Biot was made a Commander of the Legion of Honour; he was also a member of the French Academy, and of most of the learned societies in Europe. He died at Paris, February 3, 1862.—His son, EDOUARD CONSTANT, a distinguished Chinese scholar, was born at Paris, July 2, 1803. He was at first a railway engineer; but his health failing, he retired from the public service, and devoted his leisure to the study of Chinese and the history of the social organisation of the Celestial empire. He was elected a member of the Academy in 1847, and died March 12, 1850. He wrote a *Dictionnaire de l'Empire Chinois* (1842), and a multitude of *Mémoires* on Chinese subjects.

Biotite. See MICHA.

Biped (Lat., 'two-footed'), a descriptive term, sometimes applied to man, but more frequently to birds. It may be used in two ways—(a) in reference to habit only (physiological), when animals use only their two hind-limbs for moving along the ground—e.g. man, kangaroo, bird; (b) in reference to anatomy (morphology), when the typical number of four limbs is reduced to two. Thus among mammals the order of whales (Cetacea) is marked by the absence of hind-limbs; among birds the fore-limbs are considerably reduced in the running birds of the ostrich sub-class, and especially in the New Zealand Kiwi (*Apteryx*); among reptiles, some serpents (e.g. Pythons) retain traces of hind-legs, while all the others have lost both pairs, and a few lizards have either only hind-feet (*Pseudopus*, *Ophiodon*), or only fore-feet (*Chirotes*); among amphibians, a few (e.g. *Siren*) have only fore-feet; and the same is true of numerous fishes (e.g. among Siluridae), and especially of those which live to a large extent in mud.

Bipinnaria, the technical name of a starfish larva. It is a curiously-shaped free-swimming form, with two ciliated bands, and with a tendency to develop long stilt-like arms or processes. It does not directly turn into the adult, but is only its 'nurse.' The adult is formed within the bipinnaria. See ECHINODERMATA, STARFISH.

Biquadratic. See EQUATIONS.

Bir, or BIREJK, a town of from 1800 to 2000 houses, of Asiatic Turkey, on the east bank of the Euphrates, 80 miles N.E. of Aleppo. Separated from Turkey by the Treaty of Versailles, it was restored by France.—The Arabic *Bir*, which signifies 'well,' is the Hebrew *Beer*.

Birbhūm, a district in the Bardwan division of Bengal, with an area of 1752 sq. m. Rice is the chief crop. The principal exports are rice and raw silk. Pop. 935,000.

Birch (*Betula*), a genus of Betulaceæ, which forms with the Alder (q.v.) the Betuleæ tribe of that family, while the Hazel (q.v.) and the Hornbeam (q.v.) form the Coryleæ tribe. There are many species of birch, all trees or shrubs, natives of northern temperate and arctic regions.—The Common Birch (*B. alba*) has small, long-stalked, somewhat triangular doubly serrated leaves. It is a very beautiful and rapid-growing tree belonging to the cooler temperate, sub-arctic, and arctic regions. In favourable situations it attains a height of 50 to 60 feet, with a diameter of 1 to 1½ feet, but diminishes in size towards its arctic or alpine limit, at last becoming a mere bush. It is for this special reason a most important tree of Northern Russia, &c., where it often forms whole woods. No other tree exists in Greenland; and according to old popular belief, it was the only tree that grew in paradise. The bark is smooth and silvery white, and its outermost layers are thrown off as the tree advances in age. The smaller branches are very slender and flexible, and in a particularly graceful variety called the Weeping Birch (*B. A. pendula* of nurserymen), they are still more slender, elongated, and pendulous. The bark and leaves of the birch are, in some northern countries, used medicinally in cases of fever and eruptions. They are also used for dyeing

Flowering Branch of the Common Birch.

yellow. The bark is sometimes used for tanning, and for steeping nets, sails, and cordage (see BARK FOR TANNING). It is in some countries made into shoes, hats, drinking-cups, &c., and is even twisted into a coarse kind of rope, and is the material of which the North American Indians made their light canoes. It is remarkable for its durability, which often exceeds that of the wood itself. In many parts of the north of Europe it is used instead of slates or shingles by the peasantry; and in Russia—the outer or white layers being subjected to distillation—there is obtained a reddish empyreumatic oil called Birch Oil, of which a somewhat tarry form, the so-called *degutt* or *degget*, is employed in the preparation of Russia leather. Dried, ground, and mixed with meal, birch bark is used in Norway for feeding swine; and in times of scarcity has even served for human food. The wood is white, hard, and tough, and is employed by turners, wheelwrights, and coopers, who use it in the manufacture of barrels for fish. Much of it is made into charcoal for forges. The twigs are in general use for besoms, and for removing the scale from armour-plates in foundries. In Britain there are two varieties of the Common

Birch (*B. alba*); one with watery twigs (*B. alba verrucosa*) is usually found on dry soil, and the other with pubescent twigs (*B. alba pubescens*) generally on wet soil. The White Birch of North America (*B. populifolia*) very nearly resembles the common birch, and is also extensively used. The Black Birch of the same country, but of more southern range (*B. nigra*), also sometimes called Red Birch, produces very hard and valuable timber. But the name Black Birch is also given to another species sometimes called the Sweet Cherry Birch (*B. lenta*), itself a large and valuable timber-tree. Its leaves make an agreeable tea. The Yellow Birch of Nova Scotia, Maine, &c. (*B. excelsa*) is a large tree with leaves 3½ inches long; its timber is used in shipbuilding. The bark of the Paper Birch (*B. papyracea*) is capable of division into very thin sheets, which have been used as a substitute for paper. It is used by the Indians and French Canadians for canoes, boxes, buckets, baskets, &c. Large plates of it are curiously stitched together with the fibrous roots of the White Spruce, and coated with the resin of the Balm of Gilead Fir. *B. occidentalis* is an interesting species found on the Pacific slope. The mountainous districts of India also produce several useful species. Thin, delicate plates of the bark of *B. utilis*, Don., are used for lining the tubes of hookahs, and were formerly used as paper. *B. alnoides*, Ham., a native of Nepal, has strong and durable wood.—The Dwarf Birch (*B. nana*) is a mere bushy shrub, seldom more than 2 or 3 feet high, and generally much less. It has orbicular crenate leaves. It is a native of the whole of the most northern regions of the globe, and is found as far south as the Bavarian Alps and Swiss Jura. It is interesting because of its uses to the Laplanders and other inhabitants of very northern regions, to whom it supplies their chief fuel, and the material with which they stuff their beds. Its seeds are the food of the ptarmigan, on which the Laplanders in a considerable degree depend. A similar shrubby species (*B. antarctica*) occurs in Tierra del Fuego.

Birch, SAMUEL, Egyptologist, was born in London, 3d November 1813, the son of a city clergyman. Educated at Merchant Taylors', in 1834 he entered the public service under the Commissioners of Public Records; and in 1836 he became assistant in the antiquities department of the British Museum. In this capacity, Birch acquired an extensive acquaintance with archaeology in all its branches. He studied not only Greek and Roman antiquities, including numismatics, but applied himself with untiring zeal to Egyptian hieroglyphics. In process of time, he so distinguished himself in this difficult branch of learning, that Baron Bunsen availed himself of Birch's knowledge in the philological portion of *Egypt's Place in Universal History*, the last volume of which, after Bunsen's death, was admirably edited by Birch. In 1844 he was appointed assistant-keeper of antiquities; in 1861, keeper of the Egyptian and Oriental antiquities. He received an honorary LL.D. from St Andrews in 1862, and from Cambridge in 1874, in which year he was president of the London Congress of Orientalists. He was a corresponding member of several academies, and was a contributor to various learned journals, to the *English Encyclopædia*, and to *Chambers's Encyclopædia*. Besides three works connected with his Chinese studies, he was author of *Ancient History from the Monuments of Egypt* (1875), *Egyptian Texts* (1877), &c. He died in London 27th December 1885.

Birch, THOMAS, D.D., an industrious historical writer, born at Clerkenwell in 1705, was the son of

a Quaker, but in 1730 took Anglican orders, and received half a dozen preferments in the course of the next thirty years. He was killed by a fall from his horse in the Hampstead Road, 9th January 1766. He was author or compiler of *Lives of Boyle, Tillotson, Queen Elizabeth, Prince Henry, &c.*

Birch-Pfeiffer, CHARLOTTE, a German actress and dramatist, was born at Stuttgart in the year 1800. She made her début at Munich at the age of thirteen, and afterwards played with great success at Berlin, Vienna, and Hamburg. In 1825 she married Dr Christian Birch of Copenhagen, and in 1837, after performing at Petersburg, Pesth, Amsterdam, and other places, she undertook the management of the theatre at Zurich. At a later period, she acquired even greater renown as a writer for the stage than as an actress. In 1843 she made an engagement with the theatre-royal at Berlin, in which town she died, August 24, 1868. Madame Birch-Pfeiffer's plays attain no very high standard, but are still popular with German audiences. A complete edition of her dramatic works has been published in 23 vols. (Leip. 1863-80), and of her novels and tales in 3 vols. (1863-65).—Her daughter, Wilhelmine von Hillern (1836-1916), was the author of *Die Geier-Vally* (dramatised by her, 1881) and other novels

Bird. Birds are in some ways the highest of the vertebrate animals. They represent the climax of that passage from water to land which the backbone series illustrates. Their skeleton is more modified from the general type than that of mammals; their arrangements for locomotion, breathing, and nutrition are certainly not less perfect; their body temperature, higher than that of any other animals, is an index to the intense activity of their general life; their habitual and adaptive intelligence is familiarly great, while in range of emotion and sense impressions they must be allowed the palm. It is, in fact, only when we emphasise the development of the nervous system and the closeness of connection between mother and offspring, that the mammals are seen to have a right to their pre-eminence over birds. Birds and mammals represent two divergent lines of progress, and stand in no close connection, but the affinities between birds and reptiles are sufficiently marked to warrant their being included in a common class (Sauropsida), in contrast to the amphibians and fishes (Ichthyopsida) on the one hand, and Mammalia on the other. Among the numerous points of difference which separate birds from their nearest relations the reptiles, and from mammals, the following may be noticed :

	Reptiles	Birds	Mammals
Covering.. . . .	Scales or scutes	Feathers.	Hair
Number of fingers. . . .	Always more than three	At most three.	Five or fewer
" skull condyles . . .	One.	One.	Two
" aortic arches	At least two.	One, right	One, left.
Diaphragm	Only incipient.	Only incipient.	Complete.
Blood	Cold	Hottest	Warm.
Position of optic lobes .	On top of brain.	At sides of brain.	Covered up
Fertilisation	Ovi- or viviparous	Oviparous.	Except two, viviparous.

But those contrasts are only a few of the less technical selected from Professor Huxley's masterly comparison of the three classes. To appreciate the full extent of the resemblances and differences between birds and reptiles, and the contrast between both and mammals, the reader must consult Huxley's *Anatomy of Vertebrate Animals*.

History of Study of Birds.—As birds are even to a careless eye most markedly separated from all other animals, there has rarely been any difficulty about the limits of the class. Aristotle (300 B.C.) defined them as feathered flying bipeds which lay eggs, and catalogued a goodly list, divided into three great orders, with the ostrich and a few others in separate subdivisions. He did not include bats in his list. For eighteen centuries no real progress was made with the study of birds. They were not of course lost sight of, but were abundantly discussed, now from a semi-religious, now from a practical point of view, yet it was not till the outburst of naturalist enthusiasm in the 16th century that they became again objects of scientific study. It is indeed curious, after a lapse of 1800 years, to find William Turner describing the birds enumerated in the catalogues of Aristotle and Pliny. Of the school known as Encyclopædists, Belon (1555) devoted himself especially to the study of birds, and made the great step of comparing the skeletons of bird and of man bone for bone. In the subsequent classificatory enthusiasm inaugurated by John Ray, and perfected by Linnæus, birds came in for a full share of attention, but the numerous naturalists who, towards the end of the 18th century, tried to put the birds in order, have left in their discrepant systems a record of the difficulty of a task which is still acknowledged to be bewildering. They fixed their attention mainly either on superficial characters, such as bills and feathering, or on general facts of habit, such as running and swimming. In other directions, however, progress was made: John Hunter (1728-93)

and Vicq d'Azyr (1748-94) made important investigations on the skeleton and musculature of birds, while Caspar Friedrich Wolff, turning in 1764 to the problem of chick-development, the study of which had begun in Greece more than nineteen centuries before, laid the foundations of modern embryology. Then followed the Cuvierian school of anatomists, and to the works of the master himself, and of his numerous disciples, most of our present knowledge of bird anatomy is due. Numerous attempts at classification were again made, but even yet no one detailed system is generally adopted. General ornithology has been greatly enriched by the monographic, and in some cases stupendous labours of enthusiasts like Naumann, Thienemann, Audubon, Gray, Wilson, Gould, Sclater, &c. In recent years we are mainly indebted to Owen and Marsh for knowledge of fossil forms; to W. K. Parker for embryology; to Sclater, Wallace, Newton, and others for distribution; and for a scientific classification to Professor Huxley.

Structure.—(a) With the general form of birds every one is familiar; the frequent length of the neck, the inconspicuousness of the fore-limbs when at rest, the length of the hind-limbs, the reduction of the tail, the boat-like form of the main body, the smooth gracefulness of the contour curves are at once evident. (b) As to the appendages, the modification of the fore-limbs for flight in the great majority of birds is the most marked characteristic. While the flying reptile, Pterodactyl, had a membrane stretched on the much elongated little finger, and the bats have their skin spread out between their elongated four fingers, the bird has never more than three fingers, and these much reduced. The stroke, as every one knows, is effected not by a stretched skin, but by the strong stiff feathers. The most marked general feature in the legs is the elongation and fusion of the bones just below the ankle (metatarsals).

The toes are never more than four, except in abnormalities, nor fewer than three, except in the two-toed ostrich. (c) The integument differs markedly from that of every other Vertebrate type in

Fig. 1.

a, fore-limb of pigeon; b, fore-limb of bat; c, fore-limb of pterodactyl.

being clad with feathers. These are skin structures generally comparable to scales or hairs. Their development will be discussed separately (see FEATHER), but it may be noted that in consequence of certain conditions of skin growth, numerous elevations are formed both of the outer and inner layers. These growing outwards, and at the same time fixed below in little pits, become to a large extent horny, and are split up in various ways to form feathers. The outermost sheath becomes a horny case which falls off as the feather grows; the feather proper is due to a horny modification of the inner stratum of the outer skin or epidermis; the inner skin (*dermis*) forms a nutritive base which, with its blood-vessels, keeps the young feather alive, but becoming subsequently reduced, leaves the perfect structure virtually dead. They do not usually occur all over the body, but in definite feather-tracts, as can be readily seen by plucking small or young birds. Some birds, however, like the penguin are really feathered all over. Three distinct kinds of feathers are at once distinguishable—(a) the small hair-like downy rudimentary *filoplumes*; (b) the numerous smaller contour or covering *plumes*; and (c) the large strong quill-feathers or *pennæ* on wings and tail. The ordinary feather consists of a quill at the base of a shaft up the centre, and of the vane borne on the sides of the shaft. The vane consists of parallel barbs, which are linked together by small barbules. The base of the quill bears a miniature feather or after-shaft, which in a few cases becomes as large as the main feather. On the bare legs of many birds the feathers are replaced by horny scales, and the horny structures forming the beak and terminating the toes are very familiar. Skin glands, so abundant in mammals and elsewhere, are here absent; but at the very end of the tail there is a two-lobed oily preen-gland, the secretion of which is used by the bird for anointing and waterproofing its feathers. Curious skin structures, such as combs and wattles, are often developed.

Skeleton.—The most important peculiarities of the bird skeleton are the modifications of forelimbs and girdle in association with flight, the abundant air-cavities (only absent apparently in the kiwi or apteryx), which make the bones so light and spongy, and the tendency the bones have to fuse together. (a) The *backbone* is very different from that of other animals. The several backbone bodies (vertebræ) have a very complex shape, and are not to be mistaken for those of any other vertebrate. While the neck of mammals almost

always consists of seven vertebræ, that of birds includes a larger and variable number, amounting to over a score in the swan. Unlike the very movable neck, the dorsal region tends to become more or less rigid, especially behind, where a large number of vertebræ enter into immovable connection with the hip-girdle. Behind these there are a few caudal vertebræ which are again mobile, and end in a compound ploughshare-bone which bears the great steering feathers of the tail. The most anterior ribs are fused to the vertebræ; then follow a few (two in the fowl) which are free, but do not reach

Fig. 2.—Skeleton of Fowl (exhibited in section):

the breastbone; the next set meet, at an angle, upward processes from the breastbone, with which they are thus indirectly connected. The last ribs are again free. Almost all the ribs bear backward directed (uncinate) processes which overlap the rib behind. These also occur in crocodiles. (b) The *skull* of course corresponds in general structure to that of other vertebrates, but is distinguished by the early fusion of the component bones, so that the contours are no longer visible, by the prolongation of the front bones to bear the beak, by the absence of teeth, by the large sockets for the eyes separated from one another only by a thin (sometimes perforated) partition, and by the marked lightness of the bones. There is only one ball (condyle) which turns on the cup of the body of the first (atlas) vertebra, the bone (quadrate) on which the lower jaw works is movable, the portion of the skull lying in front of the eye-sockets is slightly movable on the portion protecting the brain, the tongue-bone (*hyoid*) is very well developed. It is on the relations of certain bones of the skull that Huxley bases his anatomical classification. (c) *The limbs.*—The *shoulder-girdle* consists (1) of a long bone running backwards (the shoulder-blade or *scapula*), (2) of a shorter bone running from the shoulder down to the breastbone (the

coracoid, only a process of the scapula in mammals), and (3) of a slender collar-bone (*clavicle*) which extends from the shoulder to meet its fellow in front of the breast, forming with the broad uniting plate the familiar 'mergthought.' The breastbone or sternum forms the base of attachment for the great muscles which work the wings, it is concave

Fig. 3.—Breastbone and Shoulder-girdle of Falcon:

a, clavicle; b, scapula; c, coracoid; d, keel of sternum; e, ribs.

internally, and in most birds bears a prominent ridge or keel on the middle line in front. As this ridge serves for the fixing of the flight muscles, it is largest in the birds which use their wings most, and absent in those, such as the ostrich family, which use them either not at all, or very little. The flying keeled birds (*Carinatae*) are in the immense majority; the running birds, with flat raft-like sternum (*Ratitae*), are few. Even among birds of flight, comparative disuse of wings may be associated with a slight development of the keel. In the New Zealand parrot (*Stringops*), and a few more, the keel is very rudimentary. The arm consists as usual of a strong upper bone or *humerus*, working in the socket formed by scapula and coracoid, of two bones forming the forearm, the *radius* and the stronger *ulna*, of a single pair of wrist-bones, and of three fingers. The three bones corresponding to the palm of the hand (the *metacarpals*) are fused together, and also with the distal carpals, forming a *carpo-metacarpus*—i.e. half of the wrist and the whole of the palm. The thumb and first finger are sometimes clawed. In the kiwi and the emu there is only one complete finger, apparently the second. The feathers attached to the hand are usually called primaries, and those borne on the ulna, secondaries. The *hip-girdle* is very long, and its most important part consists of two dorsal bones (*ilia*) which are fused to a large number of posterior backbone bodies. A second

Fig. 4.—Hip-girdle of Fowl:

a, ilium; b, ischium; c, pubis; d, socket.

portion (the *ischium*) extends backwards on either side, nearly parallel to the hind part of the ilium with which it is firmly fused. The third part (or *pubis*) also runs backwards from the socket of the thigh, and is a slender bone nearly parallel to the former. Only in the ostrich (*Struthio*) do the two pubes really unite; but in other birds they are bound together by fibrous tissue. In the American ostrich (*Rhea*) the two ischia are united ventrally. The socket formed by the union of the three portions of the hip-girdle is incompletely bony (perforate), as is also the case in one of the lowest mammals, the porcupine ant-eater, or *Echidna*. The thigh (*femur*) is a short stout bone. It is followed by the two bones of the lower leg, one of which (the *fibula*) is always imperfect and fused to the strong *tibia*. The knee is generally protected by

a knee-pan or *patella*. The ankle is peculiar in this, that the upper tarsals unite in the adult bird with the lower end of the tibia, which is therefore known as the *tibio-tarsus*, while the lower tarsals unite with three of the bones corresponding to the sole of the foot (metatarsals), thus forming an absolutely characteristic bird bone, known as the *tarso-metatarsus*. In the adult there are thus no distinct ankle bones or tarsals, these having become fused to the tibia above, and to the three fused metatarsals below. If there are four toes, the first is turned backwards, and its metatarsal remains quite separate. But in many birds the first toe is wholly undeveloped. The

Fig. 5.—Feet of various Birds:

a, swift; b, stilt; c, black stork; d, wryneck; e, falcon; f, raven; g, kingfisher; h, pelican; i, grebe; k, coot; l, snew-duck

ostrich has only two toes. In most cases the number of joints in the toes increases by one, from two in the first to five in the fourth toe. The toes vary considerably in direction according to the way they are used. A bony spur ensheathed with horn is sometimes developed (as in the cock) in connection with the metatarsus.

Muscular System.—The most important muscles of the bird are those which work the wings. These lie on the breastbone, which forms their base of attachment. The great pectoral muscle which forms the greater part of the breast depresses the wing; a second smaller and deeper muscle, covered by the former, is continued into a long tendon which passes through a hole at the shoulder-joint, is inserted on the back of the upper arm, and raises the wing; a third much smaller breast muscle also assists in elevating the wing. It is well known that birds may remain firmly perched when asleep. This is effected by an automatic muscular arrangement. The tendon of a muscle which bends the toes passes up to the hip over the knee-joint, so that when the knee is bent in perching, the tendon is stretched, and the toes are kept firmly fastened. There is a strong development of muscles in association with the gizzard or stomach-mill.

Nervous System.—The brain of birds is markedly more developed than that of reptiles, the parts no longer lie almost on one plane, and the organ occupies the whole of the spacious skull-case. The convolutions characteristic of the fore brain of mammals are not yet developed. The 'twain brain (*optic thalami*) is quite hidden, the mid brain (*optic lobes*) is thrust to either side, the hind brain

(*cerebellum*) exhibits cross grooves. There are twelve pairs of nerves given off as usual from the brain. The spinal cord exhibits in the hip region a conspicuous enlargement due to the divergence of its two sides. The *sense-organs*.—In association with their manifold experience, birds have well developed sense-organs.

Fig. 6.—Brain of Pigeon: *a*, fore brain; *b*, cerebellum; *c*, optic lobes; *d*, medulla oblongata; *e*, spinal cord; *f*, olfactory lobe; *g*, pituitary body; *h*, pineal gland.

This is especially true of the eyes. They are large and powerful, and can be rapidly accommodated to different distances. They differ only in minor points from those of any vertebrate. The form is far from spherical, the front portion being protruded, and to a certain extent constricted off from the ball behind. A special ring of small bony plates protects the base of this anterior portion. A comb-like nutritive fold (*pecten*), absent only in the kiwi, projects from behind into the posterior chamber of the eye. A third transparent eyelid or nictitating membrane (not restricted to birds) is conspicuously developed, and can be drawn like a screen across the eye. It lies hidden in the anterior corner. Tear and other glands are present. The ear differs markedly from that of mammals in the absence of any external

Fig. 7.—Head of Falcon, showing beak, nostril, eye, and ear; opening exposed by removal of feathers.

portion. In the birds of prey, however, a membranous flap is present. The external opening is usually surrounded by a circle of fine hair-like feathers. As regards ear bones, only one (the *columella*) is present, and in this particular also the bird ear differs from that of mammals. The snail-like coil of the ear-cavity (the *cochlea*) is also much simpler. The (Eustachian) tubes which lead from the ear-aperture down to the mouth, unite before they open into the latter. The nostrils are usually situated at the base of the beak, but may occur further forward, and in the kiwi are situated at the very tip. In some cases they are guarded by bristles, in other cases prolonged into a tube, but are usually simple apertures. The nasal cavities may communicate with one another, and contain two or more glisty or bony scrolls. A peculiar nasal gland is present. The sense of smell is undoubtedly less developed than those of sight and hearing. Taste is also but slightly developed, and is discharged by the nerve terminations on the tongue, and by a soft patch of skin (*cere*) usually situated on each side of the base of the beak. In rare cases (e.g. in mud-grubbing birds) a much larger area of the Bill (q.v.) may remain soft and sensitive.

Alimentary System.—The character of the food-canal differs widely in different birds, varying with the nature of the food. Even in one bird the difference of food at different seasons, such as the change from fish to grain in the gull, may be

associated with a marked change in the nature of the stomach. The beak may be helped by the tongue in taking up food, but in the absence of teeth no real mouth mastication takes place. The tongue varies widely in form, being not unfrequently notched and rough, and varies in size from

Fig. 8.—Beaks of various Birds:

the rudiment found in the pelican to the long protrusible organ of the humming-bird. Salivary glands open into the mouth-cavity, which in some cases (e.g. pelican) is enormously distended, and can hold quite a store of food. The gullet is soft and

elastic, in obvious association with the downward passage of unmasticated food. In many birds it dilates into a spacious thin-walled sack, known as the crop, in which large quantities of food can be stowed away. It is from the crop that pigeons obtain the soft milky stuff with which they feed their young. In most birds the succeeding portion of the canal is divided into two (and sometimes three) distinct parts—the glandular and the muscular stomach. In the first (the *proventriculus*) the food begins to be digested, in the second (the *gizzard*) it is subjected to grinding. The former is characterised by thick, soft glandular walls, and near it the blood-gland, known as the spleen, is situated. Most people are familiar with the large hard gizzard of fowl or pigeon, with its very thick muscular walls lined internally by hard secretion. The cavity usually includes small stones, and by the approach of the two sides

Fig. 9.—Alimentary Canal of Pigeon:

a, crop; *b*, proventriculus; *c*, gizzard; *d*, intestine.

The cavity usually includes small stones, and by the approach of the two sides

the food is very effectively ground. The changes dependent upon food, above referred to, are expressed in the varying preponderance of glandular and muscular regions. The exit from the stomach is turned upwards (as in crocodiles), so as to lie very near the entrance. Of the long small intestine and the short large one, of the blind processes given off at the commencement of the latter, of the associated liver (very often without a gall-bladder) and pancreas, there is little of much interest to notice. The gut ends in a common chamber or cloaca, which also receives urinary and genital products. The back wall of this common chamber is connected with a peculiar sac with glandular walls, especially prominent in young animals, but of dubious import.

Vascular System.—The heart of birds shows a marked advance over that of reptiles, in the complete separation of arterial and venous blood. Like that of mammals, it is perfectly four-chambered. The blood-vessel arrangements also resemble those of mammals in the presence of a single main branch (*aortic arch*) conveying pure blood from the heart to the body; but this runs to the right instead of to the left. The most remarkable physiological fact about the blood is its high temperature of 100° to 112° F., greater than that of mammals by 2° to 14°. Birds agree with mammals in being 'warm-blooded' or stenothermal; that is to say, they have an automatic thermotaxic mechanism which enables them to keep the temperature of the body almost quite constant, year in, year out.

Respiratory System.—The two lungs do not lie freely in a closed space, as in mammals, but are fixed to the ribs of the bird. They are non-expandable, and breathing out is the active part of the respiratory process. They are also peculiar in the way the bronchial tubes branch and in being continued into Air-sacs (q.v.). These air-sacs are

Fig. 10.—Lungs of Bird :

a, base of trachea; b, b, bronchial tubes; c, branches of bronchi; d, blood-vessel.

large but thin-walled bags, nine in number. They are connected on the one hand with the bronchi, on the other, as John Hunter showed, with the air-spaces found in the spongy bones. The air-sacs aid greatly in economising respiration by acting as extra reservoirs, and they assist in regulating the body temperature by acting as organs of internal perspiration. Birds usually require much water, and yet there is little water included in the urine. The surplus water seems to be got rid of by a sort

of internal sweating in the air-sacs. There is no skin-sweating such as mammals show. The wind-pipe or *trachea* is often very long and coiled, and is strengthened by gristly or bony rings. It sometimes comes into very close association with the breastbone, running through part of it in the swan. At its upper end there is, as usual, a larynx; but this is not the vocal organ of birds. Further down, at the point where the windpipe divides into the two bronchial tubes, lies the seat of all the music, the sing-box or *syrrinx* (see the paragraph on Song).

The Excretory System.—A pair of three-lobed kidneys embedded under the shelter of the hip-girdle perform the usual function of getting rid of nitrogenous waste. They are connected by a pair of ducts (*ureters*) with the cloaca. There is no urinary bladder. The urinary secretion is semi-solid, and rich in uric acid.

Reproductive System.—The male reproductive organs (or *testes*) are paired, and lie in front of the kidneys. The left is very often larger than the right. They are connected by a pair of ducts (*vasa deferentia*) with the common chamber, the wall of which occasionally bears a copulating organ. The female organs are peculiar in this, that in the adult the left side predominates over the right. In the embryo two ovaries are present; in abnormal and in a few exceptional cases (diurnal birds of prey) they may persist; usually, however, the right wholly degenerates. And similarly with the ducts, but the rudiment of a right oviduct is present. The end of the left oviduct is expanded to receive the ova as they burst from the ovary; the upper part of the duct is glandular, and equips the eggs with albumen; the lower is firmer, and contributes the limy shell; and the end opens into the cloaca whence the eggs are laid.

Nutrition.—The food of birds varies greatly, not only in different birds, but also to some extent at different seasons. Some are vegetarians, feeding on the green parts of plants, and in these the intestine is as usual long. Some confine themselves to grain, and these have large crops and powerful gizzards, while others combine cereals with insects (usually then without crop), or with the green parts of plants. A few sip honey, and a large number feeding on fruits probably play an important part in the dissemination of seeds. In insectivorous and fruit-eating birds the crop is usually absent, and the stomach only slightly muscular. Others again are notoriously carnivorous, or feed upon fish and molluscs, and in these cases the glandular predominates over the muscular portion of the stomach. The kea (Nestor) of New Zealand, originally a fruit-eating bird, has recently developed an alarming fondness for the blood and fat of living sheep. The interest of the nutrition of birds is twofold: on the one hand, in relation to the modifications of the alimentary system; on the other hand, in respect to the rôle of birds in the economy of nature. The experiments of John Hunter on the changes in the stomach of gulls consequent on a change of diet have been corroborated and extended. Such changes appear to occur normally in nature. Food is also said to have an influence on colour—e.g. in bullfinches and parrots.

Locomotion.—Most birds use their wings in flight, the feather-covered arms being raised and depressed with great rapidity by means of the breast muscles already described. Every one who has watched birds is familiar with the marked differences in rapidity and mode of flight. It has been calculated that a common average of rapidity is about 40 to 60 feet per second, but records of the feats of carrier-pigeons, &c. certainly greatly surpass this. It seems probable that strong-winged birds, like eagles, can cover about 80 feet in a second. Buffon noted that they disappeared from sight in about three

minutes. It is safe to say that a rate of a mile per minute is very common. Strong birds, like the albatross and birds of prey, can not only fly very rapidly, but can sustain their exertions for long

Fig. 11.—Wing of Pigeon, showing primary (a) and secondary (b) feathers, and 'bastard wing' (c) at thumb.

periods, while many other birds rarely take prolonged flights, except during migration. The wings of penguins have become flippers, and some other aquatic birds, like the steamer-duck, use them as paddles, auxiliary to the legs. On the ground birds vary greatly in rate and manner of progression; the swift strides of the ostrich, the rapid run of the partridge, the hopping of the sparrow are well-known illustrations of different gaits. That many birds are expert divers and climbers is also a familiar fact. See FLIGHT OF ANIMALS.

Respiration.—The great activity of birds is associated with very efficient respiration. Expiration, or the expulsion of used air, is managed by the contraction of breast and abdominal muscles, which compress the inclosed cavities and force the air from the sacs and lungs. When these muscles are relaxed the cavities again elastically expand, and fresh air rushes in by the windpipe to lungs and air-sacs.

Song.—With few exceptions, birds have a vocal organ, and are able to produce more or less variable sounds. The organ is, however, wanting in the running birds, such as the ostrich, and in the American vultures. The sounds produced are almost as varied as the different kinds of birds, and an expert ornithologist has little difficulty in identifying a great number of forms by their distinctive noises. That some chirp and others scream, that chattering describes the language of many and croaking that of others, that some boom and others bark, that the crows caw and the laughing jackass laughs, that the mocking-bird imitates and the parrot becomes able to articulate, and above all that the lark trills and the night-gale truly sings, are well-known illustrations of the variety of bird language. The weird cry of the curlew or whaup, the melancholy voice of the seamew, the gabble of ducks, the crowing of the cock, the soft cooing of the dove, the hoarse voice of the corncrake, the ecstatic melody of the bobolink, the cheerful notes of the blackbird, the educated music of the canary, are again a random selection of instances from an almost infinite medley. It is among the so-called perchers, songsters, or insensates, that we find song really developed, and that for the most part in the males, and in highest degree at breeding time. Though the notes are not musically pure, many bird songs have been expressed in musical notation, and every one is familiar with imitations in word form.

In mammals the voice is produced by the

mechanism of vocal chords situated in the larynx at the top of the windpipe. In birds these vocal chords are never present, but their absence is compensated by the development of a sing-box (or syrinx) at the base of the windpipe. In some cases the sing-box is wholly produced from the base of the windpipe (or trachea)—e.g. in *Thamnophylus* and American Passerines; in a few cases the mechanism is confined to the beginning of the bronchial tubes (e.g. *Steatornis*); in the great majority of songsters the syrinx includes the base of the trachea and the tops of the two bronchi. The mechanism is a very variable one, and even in its simplest forms not to be understood by any verbal description unaccompanied by dissection of a few typical singers. To take a typical example of a lower larynx or syrinx of the last and commonest construction, we find (a) that the base of the trachea and the tops of the bronchi are altered by lateral compression or by expansion, by fusion of several of the strengthening rings, or by incompleteness of some of the same. (b) The end of the windpipe is divided by a bony ridge, rising up at the angle where the two

Fig. 12.—Syrinx of Thrush, partly dissected.

bronchi unite, and forming the main stay of the resonating cavity known as the 'tympanum.' (c) From this bony ridge to the median surface of each bronchus stretches the 'internal tympanic membrane.' (d) Between the last tracheal and the first bronchial ring, or between a pair of modified bronchial rings, stretches a second 'external tympanic membrane.' (e) In singing-birds there is a third important inward projecting 'semi-lunar membrane.' (f) Besides these there are vocal membranes or folds of skin, projecting inwards in both bronchi. The tension of the membranes is varied by the action of special muscles; their vibration as the air passes over them causes sound; the note varies with their muscular state, with that of the tympanum, and with the column of air in the windpipe.

Singing is an unbidden expression of emotional energy. It is most marked at the high tide of sexual emotion during the breeding-season. It is best, sometimes solely, developed in the males, who use their powers to attract the females, and often vie with one another in so doing. In other cases the note is obviously used as language, expressing alarm and the like, for that some birds are able by voice to convey impressions to one another is indubitable. In so far as the song is an instrument and expression of sexual attraction, it falls to be included among those powers which have been strengthened and developed by sexual selection.

Moulting (q.v.).—After the strain of the reproductive period, or sometimes at the low ebb of mid-winter, the old feathers drop off, and birds undergo annual moult. The use of this in replacing breakage, and in furnishing a complete machinery for the flight of migration, is very evident; the cause is not yet sufficiently investigated. Moulting obviously presents some analogies with skin-casting and hair-shedding in other animals, and must be associated with some deep-seated constitutional change, such as its connection with the end of

the breeding-season suggests. Besides this annual growth of new feathers, many birds exhibit double, and some triple moulting. The ptarmigan, for instance, changes its suit three times in the year, moulting after breeding into gray, changing this for white as the winter sets in, and acquiring in spring a third and most attractive set of feathers. In association with sexual attraction many male birds seem to undergo a partial moult, as the result of which they acquire those special decorations which are the index of a reproductive climax.

Reproduction.—Birds usually pair in spring-time, but to this rule there are many exceptions. Fertilisation is internal, and all birds are oviparous. The number of eggs is often in inverse proportion to the size of the bird. Several, such as the apteryx, lay only one; the doves and the birds of prey lay two or three, but the majority of birds many more.

The Sexes.—The male birds are often markedly different from the female. In the Bird of Paradise (q.v.), for instance, the two sexes are at first alike, but with successive moults and increasing maturity, the male becomes in colour and plumage a most marked contrast to the comparatively sober female. The contrast between peacock and peahen is a yet more familiar illustration of a very widely observed fact. In rare cases the female is the more brilliant. The male has also a richer and more varied voice, and in many cases the singing is all on his side. Both with song and with dance, by strains of love and display of charms, by the wildest excitement of aerial evolutions, and by the most grotesque of striking attitudes, the males strive to captivate the females. For the details of this sexual attraction, and for the importance of sexual selection in evolving decorations and charms, the reader may be referred to Darwin's *Descent of Man*, where the subject is very fully discussed. Birds associate together to very different degrees; thus, eagles live separately, the two sexes only coming together at breeding time; the doves live in pairs; many birds are similarly monogamous, but live in society, except during the breeding-season, while fowls and some running birds are polygamous, one male ruling over a number of females. See SEX.

Eggs.—The size of the egg is very generally proportionate to that of the parent, but there are many striking exceptions. The very centre of the egg contains what is known as white yolk which rises as a plug to the surface. This white spot, usually lying uppermost when the egg is opened, is the area (*blastoderm*) where by the multiplication and arrangements of cells the embryo chick is mapped out. The 'yellow yolk' is traversed by concentric

Fig. 13.—Section of Fowl's Egg:

a, central plug of white yolk; b, position of germinal area; c, yellow yolk; d, white of egg; e, 'tread' or chalaza; f, air-space between outer membranes.

layers of white, which also forms a thin layer round the outside. As the egg passes down the upper portion of the oviduct it becomes coated with

fluid white of egg or albumen, which is separated from the yolk by a (*vittelline*) membrane inclosing the latter. The fluid albumen is also disposed in layers, separated by fibrous networks, and almost every one is familiar with two thick sets of fibres (known as the 'tread') which extend from each end of the yolk into the surrounding albumen. In the lower portion of the oviduct (the *uterus*) the egg becomes, as we have already noted, inclosed in a limy shell. This is an organic structure and is two-layered. Its texture and microscopic characters differ in the various orders, and appear to be truly diagnostic. The shell is separated from the white of egg by a double membrane, the two layers of which become separate at the broader end, and leave a familiar air-space which increases with the age of the egg. The form of the finished egg varies from an approximately perfect sphere to more or less symmetrical ovals. In the uterus the shell usually becomes stained by complex secretions of pigment which in some respects resemble those of the blood and bile. As many as seven distinct pigments have been distinguished by Mr Sorby. It is necessary to distinguish the ground colour from the subsequent more or less circular markings, which become variously blotched and distorted by the movement of the egg in the uterus. The markings are not always constant, but vary with age and even in the same brood. The colouring is apparently to some extent protective against the sun rays, and varies also according to exposure. That the colour of the eggs often favours their being overlooked by enemies is a familiar fact. Though the older naturalists, before the collecting of eggs had been superseded by embryology, doubtless exaggerated the importance of their science of 'oology,' it is also certain that some important hints in classification have been afforded by the study of the characteristic colouring. The extraordinary enthusiasm exhibited by egg-collectors, from the time of Sir Thomas Browne's cabinet onwards, is a most remarkable side chapter in the history of science, which has been recapitulated in the lives of many of our famous naturalists, and indeed in the boyhood of almost every boy bred in the country. See EGG, CAGE-BIRDS, INCUBATION.

Development.—The development of the embryo bird will be discussed along with that of other backboned animals (see EMBRYOLOGY); but a few general facts (with special reference to the fowl) may be noticed here. The egg is fertilised in the upper part of the oviduct before the coating of albumen is added to the ovum proper. The usual division commences in the lower part of the oviduct, shortly before the shell has begun to be formed. Owing to the vast amount of nutritive, as opposed to formative material, the whole ovum does not divide, but only a special part of it, known as the germinal disc. It is also noteworthy that the division proceeds somewhat unsymmetrically. The subsequent changes by which the different germinal layers are established, and nervous system, backbone, gut, muscles, and the organs generally are formed, cannot be here discussed. The development of the chick excited interest even among the old naturalist philosophers of Greece, and we have not finished the inquiry to-day. It was by observation of the embryo chick that Wolff first showed distinctly (in 1759) that development was a matter of gradual growth, and not the unfolding of a miniature ready-made organism. It was in regard to the fowl that Pander (1817) first drew emphatic attention to the different germinal layers, the distinctions between which are of such importance in understanding the process of development. On the development of the chick also, Von Baer (1828-37) partly based his great generalisation as to progress

from the simple to the complex, and showed that the passage of the embryo from one great stage to another corresponds to the successive steps which mark off fish from amphibian, amphibian from reptile, reptile from bird. This law we now express by saying that the individual development (*ontogeny*) is a recapitulation of the historic evolution of the race (*phylogeny*). Mr Parker eloquently compares watching the development of a bird to reading a palimpsest; under the more superficial characters are others (at an earlier stage) more primitive, beneath those others more primitive still, till the characters are seen to be distinctly reptilian, and so on backwards. The work thus begun by Wolff, Pander, and Von Baer has been vigorously continued; many of the greatest embryologists have contributed to the elucidation of bird development; in Britain Parker especially has, with marvellous patience and skill, followed the development of the bird skull. By the recent use of the contrivance known as the embryoscope, the development of the chick has been watched going on, and even experimented upon.

The chick is inclosed in an embryonic membrane known as the amnion, and has a large respiratory sac called the allantois. The nutritive yolk which is gradually absorbed is inclosed in a 'yolk sac.' When about to be hatched, the chick thrusts its beak through the egg-membranes, and breathes the air in the air-chamber. The lungs begin to work, and the allantois shrivels up. The Umbilicus (q.v.) becomes completely closed, and the chick, piercing the shell at the broad end with repeated blows of its beak, casts off the dried remnants of allantois, amnion, and serous membrane, and steps out into the world.

The period of incubation, during which the parent, generally the female, but often also the male, sits in most cases constantly on the eggs, varies greatly, from ten days to eight weeks. The young birds may be at first naked, blind, and helpless, and are then fed by the parents till fledged (Altrices or Insesores)—e.g. Thrush, or they may be downy, active, and able at once to look after themselves (Præcoces or Autophagæ)—e.g. Chick. In some cases, however, they are hatched downy, but remain for a while helpless. See EMBRYOLOGY.

Nests.—It is important to notice that the higher development of birds, as compared with reptiles, is associated with the production of fewer offspring, but at the same time with the enormous increase of parental care and sacrifice. If the young are to be developed within the eggs, the latter must be kept at an approximately constant warmth. In almost all cases this is effected by brooding. The comfort of the parents during the hatching period is secured by the nest, which becomes further necessary for the protection of the fledglings. The nest-building instinct is not indeed the exclusive property of birds, but occurs also among insects and fishes, not to mention the numerous cases where homes rather than nurseries are constructed by animals. But it is among birds that the instinct reaches perfect development. The prolonged period of brooding, the frequent helplessness of the young, the very common arboreal habit, the not unfrequent enemies, have necessitated a most varied series of nest-building contrivances. The nest is built before the eggs are ready to be laid, and in most cases the female takes the prominent part in its construction. But both in the building and in the subsequent brooding the male may do his share, or in some cases much more. Each species usually has its own peculiar style and material of construction, though this may be adapted to varying conditions. The nests are usually solitary, more rarely grouped, and very exceptionally (as among cassowaries and ostriches)

common property. Rooks, sea-fowl, herons, are familiar examples of breeding communities, while the sociable grosbeak, the republican swallows, and a few others, form even closer associations. The cuckoo and the cow-bird have managed by a sort of parasitism to shirk their task, and quite a number of birds lay their eggs in an exceptional manner in the nests of neighbours. The beak is the organ most used in construction, but the pressure of the body may round off the forming nest, and the feet may also be used. How comfortable a nest may be made inside every one knows; how adroitly hidden it may be by external decorations of moss and lichen is familiar to every nest-hunter. All who have opportunity should examine the cases of birds and their nests so beautifully arranged in the British (Natural History) Museum in London. The smaller birds usually build the more beautiful nests, and every variety occurs, from the comparatively careless hole in the sand made by the ostrich to the skilfully suspended and neatly fashioned nest of the tailor-bird.

Without entering into details of nest-construction, the following series given by Leunis may be noted. For details, such a work as Rev. J. G. Wood's *Homes without Hands*, and for theory, Wallace's essay on Nests in his *Contributions to the Theory of Natural Selection*, may be profitably consulted. It must at the outset be again noticed that habits vary considerably, as the very diverse nests built in different circumstances by falcon, eagle, heron, &c. well illustrate. Nests are shifted to suit food-supply, and vary in structure according to the available material. And again, since nest-building is obviously an acquired habit, which gradually rewarded the species in the greater success of both parent and offspring during breeding time, it is natural to find it dispensed with in many cases where the nature of the situation rendered no actual nest necessary, or where the birds for some other reason have never learned the habit. Some sea-birds, like the auk, simply lay on the rocky ledges of their haunts; some ground-birds simply deposit their eggs on the bare soil.

(1) *Burrowed holes* are made by sand-martins, bee-eaters, penguins, kingfishers, and many others. The prairie-owl, living in the burrows of the prairie-dog and of the armadillo, is a well-known example of peculiar habit, and in the first case of curious partnership. (2) *Ground-nests*, generally of the simplest character, with rough and scanty accumulation of nest material, are made by swans, ducks, geese, fowls, gulls, waterhens, corncrakes, &c. (3) *Mud-nests*, constructed from damp earth, are well illustrated by the house-swallows, blue-creeper, flamingo, &c. The common singing thrush is well known to make a firm nest of clay and cow-dung mixed with moss. (4) *Carpenter-nests*, formed with more or less preparation in the holes of trees, are used by woodpeckers and a few other arboreal birds. (5) *Platform-nests*, simply consisting of flat seats, are formed by the ring and turtle doves, by eagles, storks, and cranes. In some parts of the Continent the flat nests formed by the storks on the tops of buildings are familiar enough objects. (6) *Basket-nests* are such loosely interwoven constructions of grass, stems, twigs, &c., as are made by crows, missel-thrushes, and most singing-birds. The green weaving-birds (*Ploceus pensilis*) hang their loosely woven nests, with downward directed opening, on the Madagascar trees. The South African republican birds (*Philetarus socius*) form hundreds of hanging nests on the branches, under the shelter of a common thatch. (7) *Woven nests* are the more delicately constructed and really woven constructions of wool, hair, bark, grass, &c., which are made by

such birds as the goldfinch, the Baltimore bird, and very many others. (8) *Sewed nests*, composed of leaves sewed together by the beak as needle, are well illustrated by various species of *Icterus*, and by the Indian tailor-bird (*Orthotomus benettii*). (9) *Felt-work nests* are woven from the wool of plants or animals, sometimes with other material in addition; the humming-birds and the bullfinch form beautiful nests of this fashion. (10) *Cement-nests* are bound together by a viscid and very adhesive secretion, which is mixed with saliva, and used to glue the materials of the nest together. The nests of the American swallow, the edible birds' nests of the Salangani, sought after as luxuries by Chinese and others, are of this cemented type. (11) *Dome or moss nests* are roofed in above, and have an entrance on the side. The common wren, the water-wagtail, and the tits build on this principle. The beautiful bottle-shaped nest of the titmouse is one of the best examples. (12) The *parasitic* habit is well known among cuckoos and cow-birds. The nest of another bird is utilised to the future loss of the rightful inmates, and with obvious economy of labour on the part of the intruders. Thus sparrows usurp the nests of swallows, and starlings those of woodpeckers. Pheasant and partridge eggs are sometimes found in the same nest, and the same has been observed in many cases—e.g. gull and eider-duck. When artificial nests are forthcoming, birds are glad to be relieved of the labour of construction, and different birds thus sometimes share a common box. The resorts of birds, when convenient nooks are available, are often extremely curious.

Migration.—It is a well-known fact that comparatively few birds (at anyrate, outside of the tropics) remain in the same place all the year round. They do not hibernate, but migrate on the approach of cold. Some we know as winter visitors returning north again in spring, most we know only in summer, for in autumn they fly to the warmer south; a third set we call 'Birds of Passage,' for these we only know somewhat incidentally as they pass through on their way elsewhere. Thus the swallow, the cuckoo, the nightingale, &c. come to Britain in summer and breed there, being winter residents farther south; the fieldfare, jack-snipe, bean-geese, redwing, &c. reach Britain in winter, being summer residents and breeders farther north; while the little sandpipers are familiar examples of the true birds of passage which we know only for a short time as they rest on our shores in their journey south in autumn, and north again in spring. These three classes are obviously only different cases of one fact of Migration (q.v.). As this will be discussed separately, only the general facts are here to be noticed. Almost all birds are in some degree migratory. Those which breed in the equatorial regions are the chief exceptions, and even they pass from hill to valley and back again. Forms, too, which seem to be constant residents of a non-tropical country are in many cases known to exhibit a partial or a very local migration. This is true, for instance, of the common wren and the red grouse in the north of Scotland. All birds breed in the colder regions of their migration. Changes in food-supply and temperature are the most important conditions impelling them to shift their habitats. The general trend of migration is always, as indicated, towards the equator in autumn, from the equator in spring; but the investigations of the British Migration Committee have clearly shown that the courses are generally great curves. The flight is the more universal in a country the more marked the contrast between summer and winter. The annual migration from breeding areas too cold for winter

residence and food-supply to warmer subsistence areas cannot be understood apart from the history of climates. When the European climate was more equable, it was virtually indifferent to the birds where they went. As it grew colder, the birds had to fly farther and farther south every few winters. Migration has become an inherited habit, for they set about it before the impelling conditions are directly present. According to Wallace, natural selection has played an important part in confirming this habit. Many facts about migration are still utterly obscure. The power birds have of flying straight and of returning to the same locality is very marvellous. It must be remembered that a continuous tradition is sustained; those who have made the journey before guide the others. Doubtless they have memory for great landmarks. They fly across the shallower parts of the Mediterranean, where a chain of islands in this submerged tract long remained to guide them. The smaller birds usually keep nearer the ground; but it must not be forgotten that the flight is usually mostly accomplished by night. Birds generally meet in concourses, and migrate in flocks. Only a few fly alone. Sometimes the old males remain, while the others 'flit.' The return northwards is more rapid, without young ones or weaklings. The males often return first.

Intelligence and Emotions.—As birds have a full active life, with considerable variety of function, in usually complex environment, since, as we have already noticed, their sense-organs and nervous systems are highly developed, considerable exhibition of intelligence is to be expected. They seem to have great vividness of sense impressions, to judge from their power of recalling old haunts and old friends. Birds often return to the same place season after season, and they have been known to recognise an owner after the lapse of years. Their quickness of ear and power of retention are evidenced by the power some possess of learning to repeat sounds, both words and tunes. Some have exhibited marked fondness for music, and the aesthetic tastes of the Bower-bird (q.v.) excite deserved admiration. Much more is known in regard to their marvellous hereditary, general, and largely automatic reasonable habits or 'instincts,' than in regard to their power of individually adapting their conduct to novel circumstances. Their beautiful and adroit contrivances of nest-building are very familiar instances of the former, but many instances of the latter have also been recorded. Mr Romanes has collected numerous illustrations of curiosity, imagination, forethought, and instruction by experience. He notes many interesting cases of their special devices in obtaining food, in avoiding capture, and in nest-building. His valuable treasury of sifted facts ought to be consulted on this subject.

As to feelings, it is hardly necessary to refer to their unexampled exhibition of sexual emotion in song and dance, parade and display, or to the marvellous parental love and sacrifice expressed in their nest-building labours, in their prolonged incubation, and in their care for and courage in defending their brood. Subtler emotions of jealousy, both in connection with and altogether apart from sex, of affection for owners or associates, of sympathy for wounded or enfeebled fellows, are also not rarely exhibited. That a bird singing continuously for hours does not represent a rare height of emotion is not to be believed. It may be fairly said that the joyous song of the lark 'at heaven's gate' is an eloquent expression of emotion only surpassed perhaps by human music.

Distribution in Space.—It is a curious fact that though birds are able to fly far and wide, and are

much less settled than most animals, it was in relation to them that the first great essay towards an understanding of distribution was made. In 1857 Mr Sclater based, upon the facts of the distribution of perching birds (Passeres or Insectores), a division of the earth into six great regions, with characteristic fauna. These regions he termed Palearctic, Ethiopian, Indian, Australian, Nearctic, and Neotropical. For an account of the birds which especially predominate over these great regions, or others with somewhat altered limits, the reader must be referred to the works of Murray and Wallace on Geographical Distribution of Animals, and to the convenient summary of facts given by Heilprin (Inter. Science Series). Some genera of birds are very widely distributed, and almost universally represented; others, like the birds of paradise and the humming-birds, are peculiarly restricted. It hardly needs to be stated that birds have unusually great facility of dispersion; that they are more numerous in the warmer countries; that according to the nature of the region, different physiological types will predominate—e.g. insect-eating birds in the tropics, and fish-eating swimmers in the northern seas.

Distribution in Time.—(1) In the Triassic strata of New England, various kinds of footprints occur which most naturalists now regard as reptilian, though others are inclined to see in some of them the earliest hints of birds. (2) The oldest known birds are found in the Upper Oolite, the well-known Archæopteryx (q.v.), from the Solenhofen lithographic slates, and *Laopteryx priscus*, from 'a nearly equivalent horizon in the Wyoming Territory' of the western United States. The long feathered tail, the unfused metacarpal bones, the toothed jaws, and other features of Archæopteryx, are exceedingly important pristine characters. (3) In the Middle and Upper Chalk, numerous fossil birds have been discovered, especially by Marsh. These are grouped together in a somewhat mixed division of toothed birds, or Odontornithes (q.v.). Of these the most remarkable are *Hesperornis* (q.v.) and *Ichthyornis*, both with teeth. The latter had biconcave fish-like vertebrae, well-developed wings, and a keeled breastbone. The former had vertebrae much like those of modern birds, rudimentary wings, and, as one would expect, no keel on its breastbone. Its teeth were not implanted in distinct sockets as in *Ichthyornis*, but lay in a longitudinal groove of the jaw. *Apatornis* was another remarkable form, and *Enaliornis* has been found in Europe in the Upper Greensand of Cambridge. (4) In the Tertiary deposits birds become more numerous, and like those now existing. Representatives of modern genera occur from the Eocene onwards. Many types, such as the great running birds, now with restricted distribution, are found in regions far from their present habitats. A giant goose-like form, *Gastornis*, apparently exceeding the ostrich in size, has been found in France and Britain. Heilprin notes how *Leptosomus*, type of a small family now restricted to Madagascar, is found in the Eocene deposits of France. In the Eocene also occur *Megalornis*, little smaller than an emu; *Dasornis*, uniting ostrich and moa; *Odontopteryx foliapius*, 'with dental armature recalling the toothed birds' of the chalk. A crane-like genus, *Aletornis*, is frequently represented in American strata. Giant forms disappear, the running birds are driven into corners, teeth degenerate and wings develop, as the modern bird fauna is gradually approached. Those who wish to read the full story should consult especially the writings of Marsh, and in the first place convenient summaries, such as that of Heilprin.

Sub-fossil and Historically Extinct Birds.—Within comparatively recent (semi-historic)

times, the 'moas' of New Zealand (*Dinornis* and *Mionornis*), the *Aepyornis maximus* of Madagascar, the Australian *Dromæornis* (ancestor of the emu), and others have disappeared. Much more recently the dodo of Mauritius, the solitaire of Rodriguez, the crested parrot and the *Aphanapteryx* of Mauritius have been exterminated. Under separate articles some of these will be discussed. Thoughtlessness and cruelty are unfortunately tending to the extermination of some other forms.

Classification.—In 1880 Mr Sclater estimated the number of extant bird species at 10,139, and Gray's estimate was somewhat higher. To these some 200 known fossils have to be added. The classification of these numerous forms is still a matter of the greatest difficulty. The older classifications were based on the habits, or on comparatively trivial characters; but as this physiological classification has been gradually improved, it has come to be not so inconsistent as formerly, with the anatomical classification suggested by Huxley. In his famous paper on the 'Classification of Birds,' *Proceedings of the Zoological Society*, 1867, Huxley grouped birds according to certain features of the skull, and though this may seem too narrow a basis, it must not be forgotten, as W. K. Parker remarks, 'that the structures of the skull and face govern the whole body, as it were; every other part of the organism corresponds to what is observable there.' But even when the great groups are marked off on this basis, there remains the huge difficulty of the genera and species. The difficulty of satisfactory diagnosis is due to the narrow range of modification. 'One bird is so like another,' say the non-ornithologists, and Professor Huxley confesses the same in saying that 'the structural modifications which the specific forms present are of comparatively little importance; any two birds which can be selected differing from another far less than do the extreme types of the lizards.'

While there is general agreement in distinguishing three great divisions of (1) ancient birds, like Archæopteryx (*Saururæ*); (2) running keelless birds, like ostrich (*Ratitæ*); and (3) keeled flying birds (*Carinatæ*), the divergence of classification observed in grouping the last of these three divisions is very great. In many works, especially text-books, the old orders of swimmers (*Natatores*), waders (*Grallatores*), scratchers (*Rasores*), climbers (*Scansores*), perchers (*Passeres* or *Insectores*), and birds of prey (*Raptores*), are still followed. In other cases some of these are retained, and others split up or rearranged in smaller orders, and a dozen or more established in all. It seems therefore most useful simply to append the classification of Huxley, with examples showing their relation to more familiar divisions.

- I. *Saururæ*.—Metacarpals not fused. Tail longer than body. Often with teeth—e.g. *Archæopteryx*.
- II. *Ratitæ*.—None of preceding characters. Flat unkeeled breastbone—e.g. (1) the kiwi (*Apteryx*), with a big toe; (2) the 'moas,' cassowaries, and emus without a hallux; (3) the ostriches, differing from the preceding in having a long upper arm (humerus), and two (not one) clawed digits—the American ostriches or *Rheas*, with ischia (see hip girdle) united, but pubes free, and the true ostriches or *Struthios*, with the ischia free, but the pubes united.
- III. *Carinatæ*.—Ordinary birds with keeled breastbone.
 1. (a) *Dromæognathæ*.—Vomer broad behind, interposed between pterygoids, palatines, and basisphenoid rostrum—the Tinamous.
 - (b) (2-4) Vomer narrow behind, pterygoids and palatines articulating largely with basisphenoid rostrum.
 2. *Schizognathæ*.—Maxillo-palatines free, vomer truncated in front. Plovers, gulls, penguins, cranes, fowls, sand-grouse, pigeons, hoazins, goatsuckers, humming-birds.
 3. *Agithognathæ*.—Maxillo-palatines free, vomer truncated in front. Part of Geranomorphæ, the Hemipods, swifts, Passerine birds.
 4. *Sauræognathæ*.—Vomerine halves permanently distinct, maxillo-palatine, arrested (except in woodpeckers, united more or less completely). Woodpeckers, birds of prey, parrots, cuckoos, kingfishers, trogons, goose-like birds, flamingos, storks, cormorants.

While the meaning of the terms can only be appreciated with the skull in hand, the above classification is independently of value as showing what orders of birds are on anatomical grounds most nearly related.

Pedigree.—It is generally allowed that birds have risen out of reptiledom. Such an origin is suggested not only by the general fact that 'reptiles' in the wide sense form the nearest distinctly lower class, but by resemblances of structure revealed in anatomical research, and still more by the study of bird embryology. But the crowning evidence in favour of this origin is found in the primitive characters of the first known bird (*Archæopteryx*, q.v.), and by the series of forms connecting flying saurians and toothed birds. Birds are derived from the ancient reptiles or saurians known as *Deinosaurs* or *Ornithoscelida*. These lead up to the primitive birds or *Saururæ*, from which two branches diverge, represented by the keelless birds (*Ratitæ*) on the one hand, and by the keeled birds (*Carinatæ*) on the other. To discuss the nature of the step by which birds took wings and rose out of reptiledom, is to raise the whole problem of organic progress. To refer the step, as Buffon did, simply to a change in the quantity of carbonic acid gas in the atmosphere, is to give the process a false simplicity. To assume the accumulation of reptilian variations by natural selection in the struggle for existence, is the consistent Darwinian view. It is probably more correct to regard the incipient birds as, so to speak, 'fevered representatives of reptiles progressing in the direction of greater and greater constitutional activity.' Flight would be at first spasmodic, but as the structures became modified by function, would gradually become more constant and less pathological. The high temperature, the feathered skin, the flight, the hollow bones, the long rest of brooding, are probably all expressions of one predominant constitutional tendency. It must also be noted that the sacrifice of parental care justifies itself in the success of the brood. See **EVOLUTION**.

Economic Importance.—In their connection with other parts of the web-like world of life, as well as for their own sakes, birds are of much practical importance. Though eagles are sometimes destructive of lambs, the birds of prey more than make up for this by keeping down the vermin; though many birds rob fruit-trees, devour seeds, and pilage growing crops, their services in keeping away plagues of insects more than counterbalance the damage they do. That some (e.g. humming-birds) visit flowers and act probably as pollen-carriers, and that others aid in the dispersion of seeds, are minor offices. That the flesh and eggs of many, both wild and more or less domesticated, are common articles of food; that the down and feathers of some are in common use for comfort and decoration; that the excrement of others forms the useful manure known as guano, are facts familiar to all. In exceptional cases, birds may be of more curious utility, a variety of pigeon discharges the functions of a letter-carrier, falcons used to be much employed in sport, the nests of one form are eaten, and some birds are kept for amusement and decoration. And when we think of their beauty and song, we must allow that human life would be poorer without them.

Conclusion.—In many centuries, and now more than ever, birds have been studied by the naturalist. The perfection of their structure, the variety and ingenuity of their habits, and in later days the fact of their lofty ascent from lowly parentage, have afforded material for thousands of researches which, in a pre-eminent degree, have been labours of love. In the eyes of simpler men, unacquainted with the technicalities of science, the majority of

birds have for long seemed the most delightful of animals. Apart from their importance as beneficial or hurtful, apart from matters of food and sport, and apart from their ancient augural significance, birds have been universally allowed to possess peculiar charms. Their ethereal habit, their general vivacity, their grace of structure, the beauty of their plumage, the music of their song, the range of their intelligence and emotions, the mystery of their migrations, and other features, combine to make birds the first and last favourites of man. To the artist too they have supplied a wealth of colour, a variety and gracefulness of form, a suggestive beauty of pose and attitude which are not elsewhere equalled. Nor is it necessary to say that just as some of the greatest ornithologists have been at the same time poets, so most poets have been also ornithologists, or at least bird-lovers. To poets of every age and country birds have been 'symbols and suggestions,' although to too many they have been nothing more. They are emphatically the poet's animals; still he is often ignorant of their habits, according to Phil Robinson's indictment in *The Poets' Birds* (1883).

Literature.—Of the immense literature on birds, the following may be noted:

E. Alix, *Appareil Locomoteur des Oiseaux* (for mechanism of flight); Balfour's *Embryology*, vol. ii. (for development); Brehm's *Bird Life*, &c. and *Book of Birds*; Brewer, *North American Ology* (for eggs); the *British Museum Catalogue of Birds*; Bronn's *Thierreich*; Cassell's *Book of Birds and Natural History* (Martin Duncan); Darwin, *Descent of Man*, &c. (for sexual selection); Foster and Balfour, *Elements of Embryology* (for development); Gould's *Birds of Australia* (for reference); Gray and Mitchell, *Genera of Birds* (for reference); Hewitson, *Eggs of British Birds*; Huxley, *Anatomy of Vertebrate Animals* (for structure and classification); Ibis, *Journal of Ornithology*; Jerdon's *Birds of India* (for reference); Leunis, *Synopsis des Thierreichs* (for genera); Macgillivray's *British Birds* (for anatomy and genera); A. Newton and W. K. Parker in *Ency. Brit.*; Owen, *Anatomy of Vertebrates* (for structure); J. G. Romanes and Lloyd Morgan on animal intelligence; H. Seebohm, *A History of British Birds*; Russel Wallace's works (geographical distribution of animals); J. G. Wood, *Homes without Hands* (for nests and general life); Yarrell's *British Birds*; Dresser and Sharpe, *Birds of Europe*; Beddard, *The Structure and Classification of Birds*; Beebe, *The Bird, its Form and Function* (1907); W. Rothschild, *Extinct Birds* (1907).

Bird, EDWARD, an English genre painter of considerable celebrity, was born at Wolverhampton in 1772. On the expiration of his apprenticeship to a maker of tea-trays in Birmingham, where his duty was to ornament the trays with flowers and shepherds, he established himself as a drawing-master in Bristol. In 1809 he sent to the Royal Academy a picture called 'Good News,' which brought him into notice; and two of his pictures, the 'Choristers Rehearsing' and 'The Will,' having procured him influential patrons, henceforth his reputation was secure, and ere long he was elected a Royal Academician. Other pictures were the 'Field of Chevy Chase the day after the Battle,' his masterpiece; the 'Death of Eli,' a number of rather poor Scripture subjects; and the unfinished 'Embarkation of Louis XVIII. for France.' He died in 1819. His reputation now depends on such of his works as 'The Blacksmith's Shop,' 'The Country Auction,' 'The Village Politicians,' and 'The Young Recruit.'

Bird, ISABELLA (Mrs Bishop), an adventurous lady traveller, long resident in Edinburgh, visited Canada and the United States in 1854. During a six months' residence in the Sandwich Islands, from time to time she sent home glowing letters describing what she saw and did, to a sister in Edinburgh. From such materials most of her

books of travel have been compiled. Her lively and picturesque narratives of journeys made to the Rocky Mountains, to the aborigines of Yezo, to Persia and Kurdistan, to Tibet and other parts of Asia, have been very extensively read. Born in 1832, the daughter of the rector of Tattenhall in Cheshire, she married Dr Bishop of Edinburgh in 1881 (who died in 1886); and till within a year of her death in 1904, she continued her travels, her lectures, and her work at home and abroad on behalf of philanthropic and missionary objects. She was the first woman elected F.R.G.S. Among her books are *The Englishwoman in America* (1858); *Six Months among the Palm Groves of the Sandwich Islands* (1875); *A Lady's Life in the Rocky Mountains* (1879); *Unbeaten Tracks in Japan* (1880); *The Golden Chersonese* (1883); *Persia and Kurdistan* (1891); *Among the Tibetans* (1894); *Korea and her Neighbours* (1905); *The Yangtze Valley* (1899). See Life by Miss Stoddart (1906).

BIRD, ROBERT MONTGOMERY (1805-54), practised for a year as a physician, but, turning to literature, wrote three tragedies, *The Gladiator*, *Oraloosa*, and *The Broker of Bogota*; and a series of novels, comprising *Calavar* (1834) and *The Infidel* (both dealing with the Spanish conquest of America), *The Hawks of Hawk Hollow*, *Sheppard Lea*, *Nick of the Woods* (1837, a tale of Kentucky during the Revolutionary War), *Peter Pilgrim* (short stories), and *Robin Day* (1839).

BIRD, WILLIAM. See BYRD.

Bird-catching Spider, a name originally given to a large spider, *Mygale avicularia*, a native of Brazil, Cayenne, and Surinam; but now more extensively applied to a number of large species of Mygale, Epeira, and perhaps other genera. The body of *M. avicularia* is nearly 2 inches long, very hairy, and almost black. When the feet are stretched out the animal occupies a surface towards a foot in diameter. The hooks of its mandibles are strong, conical, and very black. This giant spider lives in clefts of trees or in hollows between stones, where it spins a muslin-like tubular nest. During the day the Mygale

Bird-catching Spider (from Bates).

lurks in the wide porch of its house, but issues forth at night to hunt for its prey, which, according to Bates and others, really includes small birds. They are large enough to be led about by children as playthings. It is probably a species of this genus that Dampier mentions as found in Campeachy, the fangs of which, 'black as jet, smooth as glass, and at their small end as sharp as a thorn,' are said by him to be worn by some persons in their tobacco-pouches to pick their pipes with; and to be by others used as toothpicks, in the

belief of their having power to expel the tooth-ache.

Mygale or Avicularia belongs to that section of spiders in which there are four breathing organs instead of the usual two. The members of this tribe do not form a proper web, but live in holes in the manner above described, and gain their livelihood by hunting. But even the quieter web-spinning spiders (e.g. Epeiridæ) seem to manage occasionally to capture birds. Their tools are occasionally many feet long, and sufficiently strong to impede travellers in the forest, so that it is little wonder that humming-birds, and even larger forms, are sometimes entangled. See SPIDER.

Bird-cherry (*Prunus Padus*) is a small tree growing wild in the moist woods in Britain and through the palaearctic region. It is easily recognised by its abundant racemes of small white flowers and deciduous leaves. The drupes are small, unpalatable save to birds (whence the popular name) and schoolboys, but are sometimes used to colour wine and brandy, and are said to be eaten in Siberia. In Scotland the common name is *Hagberry*. A larger but closely allied species (*P. virginiana*), of which the fruit is used to flavour pemmican, has been introduced into Britain. The wood of both species is esteemed by cabinet-makers.

Bird-lice, a popular name for a family of insects (Mallophaga), often placed beside other lice in the order Hemiptera. These external parasites are louse-like in form, usually with a distinctly separated front ring in the breast region (prothorax), with 3-5 jointed antennæ, with biting mouth organs, and more or less of a sucking mouth. They live on the skin of birds and mammals, and eat young feathers and hairs, and also blood. *Trichodectes canis*, *Philoaterus versicolor*, *Liotheum anseris*, *Menopon pallidum*, are common species. See LICE.

Birdlime is a viscid and adhesive substance, which is placed on twigs of trees or wire-netting, for the purpose of catching the birds which may alight thereon. A common practice is to place a decoy or tame bird in a cage near where the birdlime is spread; the wild birds, attracted to the spot by the song of the tame bird, get entangled with the birdlime. It is also extensively used for catching mice, and even rats, in houses, where poison is objectionable. The birdlime is spread on a board, some toasted cheese placed in the centre, and the trap laid on the floor. The mice in endeavouring to reach the cheese, are held fast by the feet, and may be destroyed. The substance was formerly prepared from the middle bark of the holly, mistletoe, or distaff-thistle, by chopping up the bark, treating it with water, boiling for several hours, straining, and lastly exposing it to fermentation for several weeks, when a gelatinous muciilage is obtained, consisting mainly of a substance to which the name *viscin* has been applied. A second mode of preparing birdlime is to employ ordinary wheat-flour; place it in a piece of cotton cloth; tie up the ends, so as to form a bag; immerse the whole in a basin of water, or allow a stream of water to flow upon it; and repeatedly squeeze the bag and its contents. The result is, that the starch of the wheat-flour is pressed out of the cloth bag, and the adhesive *gluten* is left on the cloth. Other kinds of birdlime are made from viscous substances derived from various sources; for example, a peculiarly adhesive kind is got from a house-leek or *Sempervivum* found in Madeira and the Canary Islands.

Bird of Paradise, the common name of a family of birds (Paradisæidæ), found chiefly in New

Guinea and neighbouring islands, and remarkable for splendour of plumage. In all other respects, however, they are very closely allied to the crow family, *Corvidæ* (q.v.), to which they exhibit a great similarity, not only in the characters of the bill, feet, &c., and in general form, but also in their habits, and even in their voice. They have been the subject of many fables. The state in which their skins are usually exported from their native islands, gave rise to the notion that they were destitute of feet; and free scope being allowed to fancy, it became the prevalent belief that they spent their whole lives floating in the air, except when perhaps they suspended themselves for a little by their long tail-filaments from the uppermost branches of trees. They were supposed to feed on dew and vapour, or more substantially on the nectar of flowers. Some of them do, indeed, feed partly on the latter. Antony Pigafetta, who accompanied Magellan in his voyage round the world, described them as having legs, and stated that these were cut off as useless in the preparation of the skins; but his statement was not credited, and Aldrovandus went the length of accusing him of an audacious falsehood. Most of the characters ascribed to birds of paradise are simply to be regarded as imaginative revelling in the absence of facts; but it is also possible that some of the fables are in part due to the desire of the inhabitants of those islands in which they are found to increase the value of their skins as an article of merchandise. A sort of sacred character being attached to them, they were employed not merely for ornament, but as a charm to secure the life of the wearer against the dangers of battle. A. R. Wallace also pointed out that the Malayan traders, from whom the birds were usually bought, never saw them alive, knowing them indeed by the name *Burong mati*, or 'dead birds.' The people of Ternate call them *Manuk dewata*, or 'birds of God,' which name Buffon modified into *Manucod*. In different languages they are known by names signifying birds of the air, birds of the sun, &c. In 1760 Linnaeus described the largest species, *Paradisæa apoda*, and also referred to the King Bird of Paradise. The list was gradually increased, but our real knowledge of the group dates from Wallace's visit to New Guinea in 1857-58. Since then the quest has been followed up with enthusiasm.

The *Paradisæidæ* are comparatively small birds, but their spreading feathers are often of great length. Though allied to crows and starlings, the adult males are in beauty unsurpassed even by humming-birds. Tufts of bright feathers spring from beneath the wings, from the tail, or from the head, back, or shoulders. Trans, fans, and exquisitely delicate tress-like decorations occur abundantly, and the gracefulness of the plumage is enhanced by the brilliant colour and metallic lustre. The females are plain, sober-coloured birds, and it is only with maturity, and after successive moults, that the males acquire that brilliancy of plumage which they exhibit to such advantage in their courtships. The true birds of paradise feed on fruits and insects, and are practically omnivorous. Their mode of life is more or less gregarious. They are intensely active, flitting about the whole day long. There is still lack of information in regard to nests and eggs. Some of them may be readily kept in confinement.

The birds of paradise are usually grouped in two divisions—the *Paradisæidæ* proper and the long-beaked *Epimachidæ*—but Wallace unites these in one family. The former appear more nearly related to the crows, the latter to the hoopoes. Among the *Paradisæidæ* proper, the following species deserve special record. The Great Bird of Paradise

(*Paradisæa apoda*) is the largest species, measuring about a foot and a half in length. From beneath

The Great Bird of Paradise (*Paradisæa apoda*).

the wings of the male there springs on each side a rich tuft of long plumes, sometimes 2 feet in length. The gorgeous colours, from golden orange to blackish violet, baffle brief description. 'The loud, shrill note is the most prominent and characteristic animal sound in the Aiu Islands.' The natives shoot the males with blunt arrows when they are displaying themselves in courtship. So preoccupied are they that many may be shot before the thronging rivals take alarm.—The Lesser Bird of Paradise (*P. papuana*) is smaller and predominantly yellow, except on the breast, which is purplish. The females are white below, and so are the young males. They gradually become more brown and more handsome. This species is very frequently used for ladies' head-dresses. Its home is in New Guinea and adjacent islands. Wallace brought two live specimens to Britain, and they lived for one and two years in the Zoological Gardens in London.—Among closely related species is the Red Bird of Paradise (*P. rubra*), restricted to the island of Waigiu, near New Guinea. It is about 14 inches long, and the side plumes are rich crimson. The two middle tail-feathers form stiff black ribands, about 22 inches long. Wallace notes this bird as one of the most vivid instances of the development of colour and plumage through the selective action of the females. The natives catch them by an

King Bird of Paradise (*Paradisæa regia*).

ingenious snaring contrivance.—The King Bird of Paradise (*Paradisæa regia*, also called *Cicinnurus*

regius) is much smaller, only about 6 inches long, but is even more brilliant in plumage. The two middle feathers of this living gem are wue-like shafts, about 6 inches long, bearing at their extremities a spiral emerald disc. The females and young males are, as usual, very plain.—The Magnificent Bird of Paradise (*Diphyllodes spectiosa*) has a curious double mantle on its back.—The Superb Bird of Paradise (*Lophorina atra*) is yet rarer and more brilliant, and bears a most extraordinary shield (like another pair of outspread wings) on the back of its neck.—The Six-shafted Bird of Paradise (*Parotia sexpennis*) is adorned in many ways, but especially by six slender feathers springing from the back of the head and ending in oval webs. Wallace discovered a beautiful bird, which he called the Standard-wing (*Semioptera wallacei*), especially distinguished by a pair of long narrow white feathers, which spring from the bend of the wing, and are capable of being erected at pleasure.

Among the Epimachidæ, or Long-billed Buds of Paradise, one of the most remarkable is the Twelve-winged Paradise Bird (*Selencades alba*). About twelve posterior plumes have the midrib elongated into black wies, which curve backwards for about 10 inches. The female is not so plain as in most other species. The males are solitary in habit. These birds frequent flowering trees, are almost ceaselessly in motion, and feed to a large extent on the nectar of flowers. The great Epimache, or Long-tailed Paradise Bird (*Epimachus magnus*), 'has a magnificent tail, more than 2 feet long, glossed on the upper surface with the most intense opalescent blue. Broad brightly coloured plumes spring from the sides of the breast. The rifle-birds, or rifleman birds, of North Australia (*Ptilorhis*) are gorgeous examples of the Long-billed Birds of Paradise. See RIFLE-BIRD.

These marvellously beautiful birds have some commercial importance. 'They are the monopoly of the chiefs of the coast villages, who obtain them at a low rate from the mountaineers, and sell them to the Bugis traders.' The skull and feet are usually removed, the skin is wrappd up in palm leaves, and dried in a smoky hut. The colour is often half spoiled in the process. That the feathers are used for head-dress decoration has been already noticed.

The scientific interest of these birds is centred in the relation of the beauty of the males to their highly developed art of courtship. Wallace gives a vivid description of the excitement and display at pairing time. They meet in what the people call 'sacaleli,' or 'dancing parties,' on wide-spreading forest trees, with large but scattered leaves. A dozen or twenty fully-plumaged males then display their beauty in every variety of attitude and motion. It is believed that the males were originally like the females, as they generally are when young. Changes in colour and form gave certain males a preference in the eyes of the selecting females. The more attractive became the more successful breeders, and thus the development of their beauty is laid to the credit of their courtship. The real origin of the colour in the mature males still requires elucidation; the theory of sexual selection only shows how changes once started might be gradually accumulated and enhanced.

The birds of paradise are restricted in distribution as above noticed. Their home (New Guinea) is rugged and mountainous, and in its recesses almost inaccessible. The people are savages. 'In such a country,' says Wallace, 'and among such a people, are found these wonderful productions of nature, the birds of paradise, whose exquisite beauty of form and colour, and strange development of plumage, are calculated to excite

the wonder and admiration of the most civilised and the most intellectual of mankind, and to furnish inexhaustible materials for study to the naturalist, and for speculation to the philosopher.' See A. R. Wallace, *Malay Archipelago* (vol. ii. 1869); Elliot, *Monograph of Paradiiseidæ* (1873).

Bird's Eye. See PRIMROSE

Bird's-eye Limestone (so called from the crystalline points disseminated through the rock) is a division of the Trenton group of the Lower Silurian of North America, containing, besides the remains of brachiopods, many enormous orthoceratites.

Bird's-eye View is a term applied generally to modes of perspective in which the eye is supposed to look down upon the objects from a considerable height. In sketching or drawing a locality for military or economical purposes, this kind of perspective is always used. The great difficulty is to represent at the same time the relative heights of mountains and steepness of acclivities. But the more usual kind of bird's-eye view differs from the common perspective picture only in the greater height of the horizontal line.

Bird's-foot (*Ornithopus*), a genus of Leguminosæ, sub-order Papilionaceæ, deriving both its popular and its botanical name from the resemblance of the curved pods to birds' claws; the leaves are pinnate, with a terminal leaflet. The Common Bird's-foot (*O. perpusillus*) grows on dry sandy or gravelly soils, and is a small plant of little importance, although eagerly eaten by sheep. But *O. sativus*, an annual growing to the height of 2 or 3 feet, a native of Portugal, is cultivated in that country as green food for cattle, and is very succulent and nutritious. Like its British congener, it grows well on very poor soils. Its Portuguese name is Serradilla.

Bird's-foot Trefoil (*Lotus*), a genus of Leguminosæ, sub-order Papilionaceæ. The English name is derived from the resemblance of the clusters of pods to a bird's foot. The common species (*L. corniculatus*) is very abundant everywhere in Britain in pastures. It has a stem 6 to 12 inches in length, decumbent, and bearing umbellate heads of 8 to 10 yellow flowers, which have a rich honey-like smell. The plant has been sometimes regarded as

Bird's-foot Trefoil.

the Shamrock (q.v.) of Ireland. It is eaten with great avidity by cattle, and its deeply penetrating roots adapt it well for very dry situations.—A

larger species, otherwise very similar, with stem nearly erect, more compact heads of smaller flowers, and smaller seeds, is the Greater or Narrow-leaved Bird's-foot Trefoil (*L. major*), which also is a common native of Britain, generally found in moist, bushy places. The Winged Pea (*L. Tetragonolobus*), often separated as the type of a distinct genus on account of its quadrangular winged pods, is a native of the south of Europe, and was formerly cultivated in Sicily and Spain as an esculent; it is sometimes sown as an annual in flower-borders in Britain.

Bird's-nest is a name applied to two or more distinct plants, of similarly brownish colour and leafless habit, which are root-parasites, and grow more or less concealed under other vegetation. *Neottia* (*Listera*) *Nidus-avis*, the bird's-nest orchis, grows in dark woods, especially beech; *Monotropa Hypopitys*, a rare ericaceous plant, also grows in beech or fir woods. There is also a bird's-nest fern (*Asplenium Nidus*); and a group of Gasteromycete fungi, the *Nidulariæ* (*Cyathus*, *Nidularia*), from their cup-shape and egg-like spore-bearing masses, have also acquired the same popular name.

Birds of Prey. See BIRD; also FALCON, VULTURE, EAGLE, SPARROW-HAWK, &c.

Birdwood, SIR WILLIAM RIDDELL, born 1865, served in various Indian wars and in South Africa. He commanded the Australians and New Zealanders at the Dardanelles and in France, and later the fifth army in France. In 1920 he returned to India, to the northern command.

Biretta (Ital. *berretta*; dim. of Lat. *birrus*, 'a hooded cloak'), a square cap worn by the clergy of the Roman Catholic Church, and by some ritualists in the Anglican Church. That of priests is black, of bishops purple, of cardinals red. Originally round, its present form, with straight, erect edges, and a tuft or button on the crown, dates only from the 17th century; but the head-covering of English bishops was known as the *birretum* as early as the 13th century.

Biretta.

Birkbeck, GEORGE, M.D., distinguished for the leading part he took in founding Mechanics' Institutes (q.v.) and in the education of the working-classes, was born at Settle, in Yorkshire, in 1776. He studied medicine at Leeds and Edinburgh. Appointed in 1799 to the chair of Natural Philosophy in the Andersonian Institution in Glasgow, he delivered his first free course of lectures to the working-classes in the following year. He took a leading part, along with Brougham, Bentham, Colbette, and others, in the formation of the London Mechanics' Institute (1824)—the first of its kind in the kingdom, long called the Birkbeck Institution, and now developed into the Birkbeck College, a polytechnic aided by the London County Council. He died 1st December 1841. See Life by Godard (1884).

Birkenfeld, a former principality named from its capital, attached to Oldenburg (q.v.), but surrounded by the Prussian Rhine province, with an area of 192 sq. m., and a pop. of 50,000.

Birkenhead, a seaport and parliamentary and county borough of Cheshire, opposite Liverpool (q.v.), on the left bank of the Mersey, owes its origin to the 12th century Benedictine Priory of *Byrched*. Still in 1818 only a few straggling houses existed, and in 1821 the population was only 236. In 1836 it received the grant of a market; in 1861 obtained the privilege of returning a member to parliament, in 1918 two members; in 1877 was created a municipal, in 1888 a county borough. The Park (1867), in Claughton, is 190 acres in extent; Mensey Park, in Tranmere, of 29 acres, was opened in 1885. Notable buildings are the market-hall, the town-hall, the sessions and police courts, the borough hospital, the free library, and the public baths. A railway bridge over the Mersey at Run-corn (1869), shortened by 10 miles the distance between the Liverpool and Birkenhead docks; the Mersey railway tunnel, 1230 yards long, was opened in 1886; but the ferry-steamers are very important still. In 1824 Laird & Son purchased from the Liverpool corporation a large piece of ground on the borders of the Wallasey Pool; but it was not till 1847 that the first dock constructed by the Birkenhead Dock Company was opened. In 1857 the docks at Birkenhead were amalgamated with those of Liverpool. Including the Great Float (over 140 acres), they extend a distance of a mile, the total water area being 170 acres, with 9½ miles of quays. Much coal is shipped from the port, also manufactures of various kinds; and grain and cattle imported. To the ship-building-yards of the Messrs Laird the town largely owed its development. Near the docks are great bridge works, machinery works, engineering works, oil-cake mills, flour-mills, and breweries. Birkenhead has a school of science and art, a technical school, and a museum and art gallery. St Aidan's College, an Anglican theological college, is in the suburb of Claughton. Pop. (1871) 65,971; (1891) 99,857; (1911) 130,794; (1921) 145,592.

Birkenhead, FREDERICK EDWIN SMITH, first Earl of, a strenuous and brilliant Tory politician and lawyer, was born at Birkenhead, 12th July 1872, studied at Oxford, lectured on history, was called to the bar, sat for Liverpool (Walton) 1906-19, worked vigorously for the Ulster die-hards, and fought in the Great War. In the Coalition Governments he was Solicitor-general (1915), Attorney-general (1915-19), and Lord Chancellor (1919-22). He became Secretary for India under Mr Baldwin (1924). He wrote on legal and political matters and on Newfoundland, and contributed to this work.

Birmingham, chief seat of British metal manufactures and great hardware centre for the world, stands near the middle of England, 112 miles NW. of London. It was probably founded soon after the Saxon conquest of Mercia, but no mention of it has been discovered prior to that in *Domesday Book*. For centuries it was, no doubt, a cluster of huts around a moated manor-house on the banks of the Rea. The river is but a small one, but it was of great value in the earliest trade of the place, which was that of tanning; and, indeed, supplied the motive-power to all its machinery until the invention of steam-power, which was here brought to perfection.

Birmingham is the home of the hardware industry, everything from the most ponderous machinery to elegant trifles being made in quantity here. Amongst the eminently various manufactures are work in gold, silver, copper, brass, iron, steel, mixed metal, plated metal, glass, stained glass; japanned and electroplated goods; firearms—especially gun-barrels—ammunition, swords, metal ornaments, toys, jewellery, steel-pens, buttons, nails, screws, tools, locks, metal tubes, and machinery. Cycle-

making is an important industry, and motor-cars are largely produced. As Birmingham jewellers make some of the finest work in England, and much of the so-called 'London-made' jewellery is produced here, the sneering 'Brummagem'—first used of certain counterfeit coins made here in the 17th century—is hardly relevant.

Birmingham (*Beorming-ham*) appears in *Domesday* as *Bermingeham*. It formed one item in the great possessions given by the Conqueror to the Paganel family, whose chief seat was at Dudley Castle. The little town was given in feudal tenure to Paganel's 'dapifer,' or steward, who adopted its name. Throughout the middle ages the barons of Birmingham constantly appear as important public servants or soldiers, but they were at last reduced to one representative, who was fraudulently attainted in 1537, when the manor fell to the Northumberland family. In Leland's *Itinerary* (1538) it is described as 'a good market town,' in which 'there be many smiths, . . . loriners that make bittes, and a great many naylor's.' In the Civil War it supplied the Parliamentarians with swords, and in 1643 it was taken by Prince Rupert, plundered, heavily fined, and in large part burnt. Sheffield gradually superseded Birmingham in cutlery, but in other metal manufactures the Midlands capital increased its variety and pre-eminence. Until the 19th century Birmingham had no corporate body, and only manorial government. This was, in fact, a principal cause of its rapid rise. Men of independent thought and energy found here a place full of vitality, but free from all the restrictions by which large towns were usually hampered. Baskerville the printer carried on his business here. Willmore and Pye, the engravers, and the painters David Cox and Burne-Jones, were Birmingham men. The famous Soho Works of Boulton and Watt were at Handsworth near Birmingham, and were lighted with gas by Murdoch in 1802. The Birmingham Musical Festival, repeated every three years since 1768 until the war, was at first associated almost exclusively with Handel's music; Mendelssohn conducted *St Paul* here in 1837, and his *Elijah* was composed for the festival of 1846, when he again conducted; Gounod's *Redemption* and *Mors et Vita* were both produced here for the first time; Elgar's *Dream of Gerontius* was first given at Birmingham in 1900, and *The Apostles* in 1903. The celebration by Radicals in 1791 of the capture of the Bastille led to a serious riot, when the upholders of church and king attacked the house of Dr Priestley, then Unitarian minister here, and destroyed his library. Several other houses were burnt, including that of William Hutton, who became the first historian of the town. Thomas Attwood originated here the famous Political Union, which hastened the passing of the Reform Act of 1832, and secured the enfranchisement of Birmingham; and the town has become the headquarters of a school of politics of which the watchword is the government by the people for the people. Amongst inventors are the names of Gillott, Mason, Elkington, and Chance; Angell James, Dr Dale, and George Dawson were ministers here; Archbishop Benson was born in the town, Bishop Westcott near it, and both were educated at King Edward's school, as was also Bishop Lightfoot; and at the oratory of St Philip Neri, established by him, John Henry Newman made his home from 1848 (save during his Dublin sojourn in 1854-58) till his death there in 1880. Incorporated in 1838, Birmingham became an assize town in 1884, and a county borough in 1888; and in 1911 was greatly enlarged in area under the 'greater Birmingham' scheme, so as to include the borough of Aston Manor, the urban districts of Handsworth, Erdington, and King's Norton and

Northfield, and the rural district of Yardley. Its dimensions are now about 12 miles at its greatest length and 7 at its greatest breadth. At the same time an important reform was introduced in poor law administration, whereby practically the whole area of the city was unified in one extensive parochial authority, with a very complete equipment in the way of infirmaries, children's homes, and an institution for the mentally defective. Birmingham was made the see of an Anglican bishop in 1904, and of a Roman Catholic archbishop in 1911. The articles on Chartism, Watt, Priestley, Newnman, Bright, and Chamberlain illustrate episodes in the history of the city.

A municipal, parliamentary, and county borough, with (since 1896) a Lord Mayor for chief magistrate, it had in 1875, when Mr Chamberlain was mayor, entered on a period of remarkable municipal, social, and sanitary development. The parliamentary representatives have been increased from three (1867) to seven (1885), and to twelve (1918, for the county borough area). The 1921 census places it third among the great cities of the United Kingdom.

A large overcrowded and unwholesome area has been superseded by wide, handsome streets and fine buildings; some 3000 polluted wells were closed, and an abundant water-supply derived from an extensive gathering-ground in Wales, in the neighbourhood of Rhayader, from whence the water is conveyed to the town by an aqueduct over 73 miles long. This great engineering enterprise was completed in 1904, at a cost of £5,884,918, but a fresh aqueduct has become necessary, and is in process of formation. The sewage system is effective and economical; gas (1875) and electricity (1899) have, like the water-supply, been municipalised, and the corporation has erected baths and wash-houses, hospitals and asylums, markets and slaughter-houses. Under the Housing and Town-Planning Act of 1909 Birmingham has taken a foremost place among English towns in this movement. In addition to the voluntary efforts undertaken in two 'garden city settlements,' in which a prominent part has been taken by the Cadbury family, the corporation has carried into effect town-planning schemes in three large areas on the outskirts. Birmingham, which is served also by various canals, is a principal station on the London Midland and Scottish and Great Western systems; the new (1913) Great Western station at Snow Hill cost over £900,000. A crematorium was established in 1903. There are more than a dozen public parks and several other gardens and recreation grounds in or near the town; in addition to which the corporation has acquired an area of 120 acres of fine open common at the Lickey Hills, about 8 miles from the centre of the town. The corporation owns the tramway service, which now extends to 71 miles of route. It has also founded a municipal bank.

The town-hall dates from 1832-52; the municipal buildings (1874-78) comprise a council house and art gallery (the latter opened in 1885); and the Mason College (University) buildings complete an imposing group. Other noteworthy edifices are the General Hospital (1897), (Wesleyan) Central Hall (1903), the Exchange, the Victoria (Assize) Courts, the Midland Institute, the Post-office, the County Court, the City Education Department offices, and the New Street Railway Station. St Martin's (13th century; rebuilt and consecrated 1875) is the mother-church; St Philip's, a finely situated edifice in the style of Wren, with its Burne-Jones windows, was in 1904 selected to be the cathedral; St Chad's is the Roman Catholic cathedral; and there are in all about two hundred and seventy churches of all denominations, over a hundred of them (including mission chapels) belonging to the Church of England. Free libraries

in Birmingham date from 1860-61; and the central institute and its twenty branches possess half a million volumes. The Shakespeare Library is one of the finest in existence, and has many bibliographical treasures. There are also large photographic collections, and a library of lantern slides which are lent out to illustrate lectures.

The schools of King Edward VI. comprise a free boys' school, a high school for girls, together with several middle or grammar schools. Mason's College, founded in 1875 by Sir Josiah Mason to promote 'thorough systematic education and instruction, specially adapted to the requirements of the manufactures and industrial pursuits of the Midland district,' was opened in 1880, Latin and Greek having been added to the science classes. In 1882 and 1892 Mason's College took over most of the scientific and all the medical teaching of the Queen's College (1867); and in 1898-1900 Mason's College was merged in Birmingham University, for which, by 1899, £325,000 was subscribed, the charter being applied for and obtained in the same year, and Sir Oliver Lodge being appointed the first principal. Commerce, science, and arts rank as departments of one joint faculty, medicine being the second; provision was made for engineering in the building erected for the science department, opened in 1909.

The Municipal School of Art has its principal building close to the municipal offices, and there are eleven branch schools. The art gallery adjoins the council house, and has very fine and extensive collections. The Pre-Raphaelite school is well represented. The paintings in oil and water-colours are more than 1200 in number, and there are also large collections of drawings and etchings. An excellent natural history museum is in the same building, the collection of stuffed birds being remarkably fine. There is also a Society of Artists of long standing, which holds exhibitions twice a year. The Midland Institute, greatly developed in 1835, has a most flourishing school of music, and other educational agencies; and there is a great Municipal Technical School, founded in 1893.

The population, which in 1770 was 30,806, by 1801 had increased to 60,822, by 1851 to 232,841, by 1871 to 343,787, by 1881 to 400,774, by 1891 to 478,113, by 1911 to 840,202, and by 1921 to 919,438.

See Hutton's *History of Birmingham* (1781); Griffith's *History of the Free Schools, Colleges, Hospitals, and Asylums of Birmingham* (1861); Timmins's *Resources, Products, and Industrial History of Birmingham* (1866); Langford's *Century of Birmingham Life* (1868); Dent's *Old and New Birmingham* (1879-80) and *The Making of Birmingham* (1894); Bunce's *History of the Corporation of Birmingham* (2 vols. 1878-85; 3d vol. by Vince, 1902); *Birmingham Institutions*; University Lectures, edited by J. H. Muirhead (1911); J. H. B. Masterman's *Birmingham* (1920); and Shaw's *Municipal History in Great Britain* (New York, 1895).

Birmingham, the capital of Jefferson county, Alabama, and the most important seat of the iron industry of the southern states, is situated at the junction of several railways, 95 miles NNW. of Montgomery, with numerous foundries, mills, factories, and machine-shops. Pop. (1880) 3086; (1890) 26,178; (1920) 178,806.

Birnam, a Perthshire hill 1324 feet high, near Dunkeld, commanding a splendid view of the valley of the Tay. Birnam Wood is immortalised by Shakespeare in *Macbeth*. Opposite Dunkeld is the pretty village of Birnam.

Biron, the title of a family that has given several marshals to France. The most distinguished are these: (1) ARMAND DE GONTAUT, BARON DE BIRON, born in 1524, fought against the Huguenots at Saint-Denis and Moncontour, but

early joined and rendered great service to Henry IV. He was killed at the siege of Épernay in 1592. His *Correspondance* was edited by Barthélemy in 1874.—(2) CHARLES DE GONTAUT, DUC DE BIRON, son of the preceding, was born in 1562. His intrepid valour gained him the affection of Henry IV., and the nickname of 'Fulmen Galliæ'; but being convicted of a treasonable correspondence with Spain, he was beheaded in the Bastille in 1602.—(3) ARMAND LOUIS DE GONTAUT, DUC DE BIRON, born in 1753, fought with Lafayette in America, joined the Revolutionists in France, for whom he commanded several armies, and defeated the Vendéans at Parthenay in 1793. Accused, however, of oppression and falsehood by two fellow-generals, he was guillotined, 1st January 1794. His *Mémoires* (new ed. by Lacour, 1858) are valuable.

Biron, ERNEST JOHN DE, Duke of Courland, born in 1690, was the son of a landed proprietor in Courland, of the name of Bühren. When his mistress, Anna Ivanovna (q.v.), ascended the throne of Russia in 1730, Biron assumed the name and arms of the French dukes De Biron, and swayed all Russia most despotically, but introduced vigour into every branch of the administration. On the death of the empress in 1740 Biron assumed the regency, but three weeks after was arrested and sent to Siberia. On Elizabeth's accession (1741) he was recalled, and died in 1772.

Birr. See PARSONSTOWN.

Birrell, AUGUSTINE, was born at Wavertree, near Liverpool, 19th January 1850. He graduated at Trinity Hall, Cambridge, in 1872. Admitted to the bar in 1875, he was made Q.C. in 1893, and from 1896 to 1899 was Quain professor of Law in University College, London. In 1889-1900 M.P. for West Fife and in 1906-18 for North Bristol, he was President of the Council of Education (1906) and Irish Secretary (1907-16), introduced the Education Bill of 1906, carried the Irish Universities Act of 1908, and resigned after the Sinn Féin rising (1916). Among his writings are *Obituary Dicta* (1884, 1887); *Life of Charlotte Brontë* (1885); *Res Judicatae* (1892); *Men, Women, and Books* (1894); *Sir Frank Lockwood* (1898); *Miscellanies* (1901); *William Hazlitt* (1902); *Frederick Locker Lampson* (1920); *Collected Essays* (1922).

Birrens, a Roman station in Dumfriesshire, 1½ mile ENE. of Ecclefechan. Excavations have yielded interesting remains. Some identify it with Brunanburh, scene of Æthelstan's victory (937).

Birs-i-Nimrud. See BABEL, BABYLONIA.

Birth is generally applied to the delivery of a living child, and not to the mere expulsion of an ovum, or foetus, or dead child. Numerous medico-legal questions of importance may arise regarding the real or supposed birth of a child. Only a few points regarding the most common of these can be touched on here. (a) Has the supposed mother been delivered of a child? Was it at or about the time alleged? The fact of delivery is often concealed; sometimes it is falsely asserted. It is only for about eight or ten days after birth that, in the case of a healthy woman, physicians can tell with any accuracy the time at which delivery has taken place. It is, however, generally possible to say whether or not a woman has had a child at some time or other; so that delivery which is feigned for the purpose of extorting charity, compelling marriage, or disinheriting other parties can generally be detected by medical jurists. (b) Was the child mature when born? or sufficiently developed for it to live? A child reaches maturity about nine months after conception, when the head is covered with hair, and the finger-nails are completely formed; the average length is 18 inches, and

weight between 6 and 7 lb.; but wide deviations from these figures are met with. It is very rare for a child to live more than a few hours if born before the end of the seventh month from conception. (c) Was the child born alive? how long did it survive its birth? (see INFANTICIDE). With regard to questions of inheritance, a child is considered capable of taking and transmitting property, if it has lived for an instant, although it may not have cried or moved. See ABORTION, BASTARD, HEIR, ILLEGITIMACY, INFANTICIDE, LEGITIMATION, REPRODUCTION; for Birthright, see FAMILY, FIRST-BORN, FEUDALISM, SUCCESSION; and for Registration of Births, see REGISTRATION.

CONCEALMENT OF BIRTH is a criminal offence in the law of all civilised countries. In England, under the Offences against the Person Act of 1861, every person who endeavours to conceal a birth by a secret disposition of the dead body of the child is liable to be imprisoned, with or without hard labour, for any term not more than two years. It is not necessary to prove whether the child died before, at, or after its birth. To constitute the crime the child must be so far developed as to have had a fair chance of life when born. Concealment includes the case of the body being laid down in an unfrequented place though not hidden. Many cases dealt with are undoubtedly cases of murder through exposure. A verdict of concealment of birth can be returned on an indictment charging murder.

In Scotland, under an act of 1690, concealment of birth was construed as presumptive of child-murder, and punished with death, in all cases where a woman concealed her being with child during the whole period of her pregnancy; where she did not call for, or make use of, help or assistance in the birth; and where the child was found dead, or was missing. The case of Tibby Walker (the 'Effie Deans' of Scott's *Heart of Midlothian*) is a familiar instance. The capital penalty was first superseded by banishment; and now, by a statute of 1809, the woman is liable to imprisonment for a period not exceeding two years. Of course, this law does not apply to cases of premature birth, at least where the offspring cannot properly be called a child. In both England and Scotland the law is dictated by a desire not to press charges of murder against unfortunate women. In England, only the secret disposal of the body is punished; mere denial of the birth is not punishable. In Scotland disclosure of the pregnancy to any one exempts the woman from punishment. It has been decided that disclosure by the mother to the putative father, or even conduct implying disclosure, or confession before a kirk-session, is a sufficient defence. The punishment usually awarded for this offence in Scotland is imprisonment from three to six, and in aggravated cases from nine to eighteen months. See INFANTICIDE.

Birth, REGISTRATION OF. See REGISTRATION.

Birthday Books began in 1866 with the *Birthday Scripture Text-book* issued by W. Mack, bookseller, Bristol, who was also its joint-compiler. Success was immediate, and by 1888 about a million copies had been sold, besides about half a million of others issued by him later. His plan, soon widely imitated, was to issue a daily Scripture text-book, interleaved for the autographs of friends. Soon all the chief poets and prose-writers were laid under contribution for the like purpose. The idea was extended to include illustrations.

Birthwort. See ARISTOLOCHIA.

Biru', WALATA, or VALATA, an oasis in the Sahara, in French Sudan, 260 miles W. by N. of Timbuktu, with one considerable town and an active trade.

Bisac'cia, a town of Italy and bishop's see, 60 miles E. of Naples; pop. 8000.

Bisacquino, a town of Sicily, 27 miles S. of Palermo. Agate and jasper are found in the neighbourhood. Pop. 10,000.

Bisahir. See BASHAHR.

Bisalnagar, or VÍSÑAGAR, a town of Baroda, in Bombay Presidency, headquarters of a taluka of the same name, and a great centre of trade in the state; pop. 14,000.

Bisalpur, a town of India, in the United Provinces, 24 miles E. of Bareilly; pop. 10,000.

Biscacha. See VISACHA.

Biscay, or VIZCAYA, the most northerly of the Basque Provinces of Spain, is bounded N. by the Bay of Biscay, E. and S. by its sister-provinces, Guipúzcoa and Álava, and W. by Santander (see BASQUES, FUERO). It has an area (very mountainous in the south) of 849 sq. m., and a population of 400,000; chief town, Bilbao (q.v.).

Biscay, BAY OF (Fr. *Golfe de Gascogne*), part of the Atlantic Ocean which washes the northern shores of the Spanish peninsula and the west of France. Its extreme width is about 400 miles, and its length much about the same. The depth reaches 200 fathoms off the Spanish coast. The whole of the south coast is bold and rocky, and great parts of the French shores are low and sandy. The bay receives numerous unimportant streams from the mountains of Spain, and, through the rivers Loire, Charente, Gironde, and Adour, the waters of half the surface of France. Its chief ports are Santander, Bilbao, and San Sebastián, in Spain; and Bayonne, Bordeaux, Rochefort, La Rochelle, and Nantes, in France. Navigation of 'the bay' is proverbially trying to inexperienced voyagers, and is frequently rendered dangerous by the prevalence of strong winds, especially westerly ones. Rennel's Current sweeps in from the ocean round the north coast of Spain.

Bisceglie, a seaport of Italy, on the Adriatic, 21 miles NW. by W. of Bari, has a cathedral (12th century), seminary, hospital, &c.; pop. 32,500.

Bischof, KARL GUSTAV (1792-1870), born near Nuremberg, became professor of Chemistry in Bonn, and wrote treatises on botany, chemistry, and geology, the chief being a Manual of Chemical and Physical Geology. In 1837-40 he made important experiments on inflammable gases in coal-mines, and on safety-lamps.

Bischoff, MOUNT, a mining district in north-western Tasmania, about 60 miles W. of Launceston. In the hill from which the district takes its name Mr James Smith in 1871 discovered what is probably the richest tin-mine in existence; it is worked as an open quarry, and in course of development a large part of the original hill has been removed. Mount Magnet is in the neighbourhood, and Zeehan (q.v.) about 40 miles farther south. The post-town is Waratah. Communication is by a branch line, 10 miles long, from the Burnie-Zeehan railway, a private line owned by the Emu Bay Railway Company.

Bischoff, THEODOR LUDWIG WILHELM, an eminent anatomist and physiologist, and more especially embryologist, was born at Hanover, 28th October 1807. He studied at Bonn and Heidelberg, becoming in 1836 extraordinary professor and in 1843 ordinary professor of Anatomy and Physiology at Heidelberg. From 1844 to 1855 he filled the like chair at Giessen, where he founded a physiological institute and anatomical theatre, and from 1855 to 1878 at Munich. In the latter year he retired, and he died at Munich, 5th December 1882.

Bischweiler, a town of Alsace, on the Moder, 17 miles N. of Strasburg. Its fortifications were dismantled in 1706. It manufactures jute, cloth,

carpets, and cartridge-cases, and raises hops. Pop. 9000.

Biscop. See BENEDICT BISCOP.

Biscuit is the name given to porcelain and other Pottery (q.v.) after the first firing.

Biscuit-root, a genus (*Camassia*) of *Liliaceæ* whose bulbs ('*quamash*') are eaten by the Indians of north-west America.

Biscuits (Fr., 'twice-baked'), small, flat bread, rendered dry and hard by baking, in order to their long preservation. Biscuit-baking is rapidly becoming an industry in itself, and factories are rising up all over the country where biscuits are made in large quantities. In these factories the flour and other ingredients of which biscuits are made is never handled from the time it enters the works until it issues from them as a finished article. In the case of hard biscuits the various ingredients are run into a kneading-machine, where they are thoroughly incorporated into a stiff dough. This is then 'braked'—i.e. passed and repassed between rollers until pressed into long sheets with smooth surfaces. These sheets are then placed on a biscuit-cutting machine, which is provided with a pair of rollers set to compress the dough as it passes between them into the desired thickness. The dough is carried along by a woollen or canvas web, which delivers the dough underneath a block containing cutters which descend and cut the biscuits to the desired shape. As the block rises, the web carries the cut dough onwards, the scrap dough being collected; they next pass on to a wire frame travelling through a heated chamber or oven. The passage through the oven occupies about fifteen minutes, during which time they are completely baked. They are then carried to the packing-room, and when cool at once packed in tins. So rapidly is this operation conducted, that about 2000 lb. weight of biscuits are passed through one of these ovens every day of ten hours.

Biscuits are divided into two classes—the *unfermented* and the *fermented*. *Unfermented* or *unleavened* bread, generally known as *common sea-biscuits* or *ship-bread*, are made of wheaten-flour (retaining some of the bran), water, and common salt.

Captains' biscuits are prepared from wheaten-flour, water, with common salt, and butter, with an occasional small dose of yeast to cause partial fermentation. Milk is also sometimes employed. *Water biscuits* are made of flour and water; *hard biscuits*, of flour and water, with variable quantities of butter, spices, and sugar. *Soft biscuits* contain increased quantities of butter and sugar. *Yeast biscuits* are those the dough of which is mixed with a small quantity of yeast, yielding more porous biscuits. *Butter biscuits* are made with much butter and a little yeast.

In making fancy biscuits great care must be taken in the manipulative part of the process to incorporate the ingredients in a systematic manner. Thus, the butter is mixed with the flour in a dry condition, and then the water or milk added; and when eggs are used, they are thoroughly beaten up with the sugar (if the latter is required), and the egg-paste added to the dough, which has been previously prepared with or without butter. The various kinds of biscuits in the preparation of which yeast is employed, present a more spongy aspect than the unyeasted biscuits. Occasionally a little sesquicarbonate of ammonia (volatile salt) is added, to assist in raising the dough, and make a lighter biscuit. A great objection, however, to fermented biscuits is that they deteriorate very rapidly on keeping.

Soft or *spiced biscuits* are prepared from flour, with much sugar, a great many eggs, some butter, and a

small quantity of spices and essences. The eggs tend to give a nice yellow cream-colour to the biscuits.

The extent to which biscuits are now consumed may be learned from the fact that several of the largest biscuit-manufactories each prepare and throw into market every week from 30,000 to 50,000 lb. weight of biscuits of various kinds.

Of biscuits requiring special methods of manufacture, we may mention '*meat biscuits*,' '*digestive biscuits*,' '*charcoal biscuits*,' and what is known as the '*perfect food biscuit*.' The *meat biscuit* has not met with much favour as an article of food. It consisted of the usual ingredients of hard biscuit made up with a soup containing the soluble matters of beef. One of the objects of the meat biscuit—viz. the preservation of animal food of South America and Australia, has been attained by other preferable methods (see PRESERVED PROVISIONS). A coarse kind of meat biscuit is used for feeding dogs.

Digestive biscuits are prepared in such a manner that they may contain diastase, the nitrogenous transforming matter of malt; but whatever quantity of this substance they may contain in the condition of dough is destroyed in the process of baking.

Charcoal biscuits contain wood charcoal incorporated in their substance. The wood charcoal usually acts as an absorbent of gases, but it loses this quality when saturated with moisture; and it is in this condition, of course, that it reaches the stomach. Any benefit that may accrue therefore from the use of charcoal biscuits cannot be due to its absorbent powers. It may, however, be of some benefit by acting as a mild mechanical irritant.

Biscutella, a genus of yellow-flowered Cruciferae, consists of about a dozen species, growing in the Mediterranean region, south and central Europe.

Biserrula, a leguminous plant of the Mediterranean region, whose fruit resembles a centipede, whereby, according to some, it is disseminated by birds, which drop it when they discover their mistake.

Biserta. See BIZERTA.

Bish, BISHMA, or BIKH. See ACONITE.

Bishop. The word comes to us from the Old English *biscop*, an abbreviated form of the Greek *episkopos*—i.e. 'overseer.' In classical writers, from Homer downwards, it signifies an inspector or superintendent of any kind, though they also use it as a title of various officers with special and determinate functions—e.g. of commissioners sent by the Athenians to regulate the affairs of colonies and subject states, and of magistrates who superintended the sale of provisions in the market under the Roman empire. In the Septuagint the usage of the word corresponds, on the whole, to that in classical writers. Sometimes the sense is quite general, as when, for instance, in Job, xx. 29, it occurs as a name for God who watches over the conduct of men; but usually it denotes officers intrusted with the superintendence of some particular work, whether civil or religious. Had the history of the word ended here, it would never have come, as it actually has done, to form part and parcel of every language spoken by Christians of the East and West. It appears in Syriac and Arabic, in Spanish and German, and everywhere, even in the French *évêque*, the original Greek form may be recognised. While, however, the word itself has been retained, the sense attached to it has undergone a radical alteration. Throughout the New Testament *episcopos* is interchangeable with *presbyter*; both are synonymous titles of officers who direct the discipline and administer the affairs of a single congregation, but, from the latter part of the 2d century, it has assumed a widely different meaning, which it still retains. Instead of being synonymous

with presbyter, it implies superiority over a body of presbyters; instead of superintendence in a particular congregation, it suggests rule over a number of congregations united in a diocese. It has ceased to mark an office which may be held by many in the same place, and has been appropriated to one who is supreme over presbyters and laity within the confines of a diocese. A modern bishop occupies a position in his diocese which is unique. He alone ordains presbyters and consecrates churches. He exercises authority over clergy and laity alike. To him the duty of preaching and instructing, and of maintaining sound doctrine, is specially committed. A New Testament bishop or presbyter was the member of a council which watched over the government of a congregation. So far we are on secure ground. The proofs of the alterations which have affected the meaning of the term will be given further on. Meantime, it is enough to say that the fact is admitted by competent persons of every theological school, even by Roman Catholics, such as Dollinger, *First Age of the Church* (Eng. trans. p. 286), and is treated as probable by Estius on Philipians, and Petavius, *Ecclesiast. Hierarch.* lib. iv. cap. 2. 'The orders,' says Thomas Aquinas (on Philipians), 'were distinct, but not the names of the orders.'

The matter is indeed very different when we pass from the word 'bishop' to the history of the episcopal office. Thus, while the more learned Roman Catholics admit that the words 'bishop' and 'presbyter' are synonymous in the New Testament, they also allege that modern bishops are by divine right superior to presbyters, and are the successors, not of those who bear the same name in the New Testament, but of the apostles. The Council of Trent anathematizes those who deny that bishops are superior to presbyters, or assert that the episcopal power of ordination is common to the latter (Sess. xxiii. can. 7). True, Roman Catholic divines make some distinction between bishops and apostles, whose successors they are said to be. It is admitted that the apostles had jurisdiction throughout the world, whereas the bishop's power is restrained to a particular diocese. But the bishop, like the apostle, ordains priests, rules over them and over the laity, and this by divine and unalterable institution. The position of High Church Anglicans is much the same. They consider episcopacy as necessary, not only to the well-being, but to the being of a church. To Anglicans of the more moderate school, episcopacy is a venerable form of church government which descends from apostolic times, but they do not count it an essential matter, and they have no mind to unchurch the Protestant communities which have been formed on another model. Presbyterians, on the other hand, contend that the government of the church by presbyters has, and has alone, the sanction of the New Testament, and they reject modern episcopacy as a corruption of primitive Christianity. But at all times the Protestant churches, whether Episcopalian, or Presbyterian, or Congregationalist, have had men among them who could adopt none of these positions; who believed that the free spirit of Christianity inculcates no definite form of church government, and have regarded the varying shapes which it has assumed as things indifferent in themselves, good or bad according to circumstances, never so good as to compensate in any degree for the absence of spiritual life, never so bad as to preclude its existence. And just as there have been men who forgot disputes about church government in the interests of the spiritual life, so there have been in England, and still more in Germany, scholars who have investigated the history of episcopal power with a learning and impartiality which

is not to be found in the war of the churches. We may say, briefly, that the result of all real investigation has been to show how utterly unlike the state of the earliest churches was to anything which either exists or could be reasonably desired at the present day. An attempt will be made here to state and to arrange the facts without entering into sectarian controversy. It must be premised that the whole tradition of the church, from the close of the 2d century onwards, tells, on a *prima facie* view, for the Roman Catholic and High Church theory of apostolical succession. Each cause has enlisted consummate learning on its side. But the method chosen here has at least the advantages that it is less familiar to the mass of English readers, that it has commended itself to scholars even within the pale of episcopal communions, and that it enables us to exhibit, without prejudice to any theory, the data by which all theory must be tested and proved.

Our earliest and surest sources of information are the undisputed epistles of St Paul, and there it is significant that the word 'bishop' occurs once only, and that in the latest of his epistles (Philip. i. 1). But in one important passage the apostle makes a formal enumeration of the different positions or grades occupied by the members of the church. We use of set purpose language which is vague, because, as we shall see presently, the powers indicated are vague, at least so far as the government of the church is concerned. 'God,' he says, 'hath set some in the church, first apostles, secondly prophets, thirdly teachers, then miracles, then gifts of healing, helps, governments, divers kinds of tongues' (1 Cor. xii. 28). It will be observed that he speaks of divine appointment, not of popular choice, and the reason is plain, for 'powers,' 'gifts of healing,' 'tongues,' 'prophecy,' were obviously miraculous gifts, and the same holds good, though perhaps in a lower degree, even of teaching, as appears from 1 Cor. xiv. 26; while Paul himself is a conspicuous example of an apostle, sent neither from men nor through human instrumentality, but by God 'through revelation of Jesus Christ' (Gal. i. 1-17).

Still the question remains whether the apostolic included the later episcopal office, and to this question diverse answers are given. Roman Catholics and many Anglicans reply in the affirmative. Presbyterians and many independent scholars also urge that there is scarcely a single feature common to the two. It is only, they plead, in the teeth of history that the distinction can be reduced to one between universal and local jurisdiction. The apostles had no universal jurisdiction; and their nearest counterpart, though even that is wide of the mark, is to be found in the modern missionary. The name of 'apostle,' which occurs once only in Matthew (x. 2), and once in Mark (vi. 30), oftener in Luke, was first given to the twelve. They were sent to the twelve tribes of Israel, and they continued this work, after the death of Jesus, in Jerusalem, and then throughout Judæa. The same name was taken by Paul after he 'had seen the Lord.' Among the Jewish congregations it was extended to James, the Lord's brother (Gal. i. 19), who had seen the risen Christ (1 Cor. xv. 7), and no doubt at a very early date to others, for Paul distinguishes 'all the apostles' as a larger class from the restricted number of the twelve. In the churches beyond Judæa, Timothy and Silvanus (1 Thess. i. 1, ii. 6), Barnabas (1 Cor. ix. 5), Apollos (1 Cor. iv. 6-9), Andronicus, and Junias (Romans, xvi. 7), were all apostles. Certain conditions seem to have been required before a man was generally recognised by this title. He must have

seen the Lord (1 Cor. ix. 1), approved himself by signs (2 Cor. xii. 12) and visions (2 Cor. xii. 1). The appointment, then, of an apostle, and the qualifications according to this view were wholly different from the appointment and qualifications of a bishop. No less different are the powers in the one case and the other. The bishop is the supreme administrator within the diocese in which he is nominated, being invested therein with supreme disciplinary authority. An apostle had no authority except over churches which he had founded. Paul, believing in the truth of his gospel, was ready to proclaim it to all, but the position he adopts to the Romans is quite other than that which he adopts to churches which owed their faith to him. He will not build 'on another man's foundation;' if he hopes to impart some spiritual gift to the Romans, he adds that the benefit will be mutual (Romans, i. 12), and he almost apologises for writing to them at all (Romans, xv. 15). It was his converts who were the seal of his apostleship (1 Cor. ix. 2). Even within his own sphere there is scarcely a resemblance between the authority of an apostle and a bishop. That of the former is much greater and much less, much greater in moral influence, much less in legislative authority. Paul's rights over his converts were those of a father who had begotten them in the gospel (1 Cor. iv. 15; Gal. iv. 19): it was his duty to remind them of the gospel they had received, accompanied and attested by the gifts of the Spirit, and to admonish them in case they were unfaithful to it (1 Cor. iv. 18-21, xiv. 37; 2 Cor. xiii. 2). When he has a distinct command of the Lord, he lays down an absolute precept. 'Unto the married,' he says, 'I give charge, yea not I, but the Lord, that the wife depart not from her husband . . . and that the husband leave not his wife' (1 Cor. vii. 10, 11)—appealing no doubt to a saying of Jesus preserved in the tradition of the disciples. On other matters, and those most important, he distinguishes between his own decision and that 'of the Lord,' and does but give his 'judgment' as 'one that has found mercy' (1 Cor. vii. 10-25). He also gives his own opinion as a spiritual man to whom the really spiritual will listen (1 Cor. xiv. 37, 38), and he refers to the general custom of the churches (1 Cor. xi. 16, vii. 17, iv. 17). But the congregation administered its own affairs in a completely democratic manner. The story of the incestuous Corinthian is a crucial instance. Paul is sure of what will take place; he is present in spirit at the meeting of the believers, but it is the meeting itself which passes sentence of exclusion. 'St Paul's spirit,' as Bishop Ellicott puts it, 'with the associated power of Christ, is present with the convoked synod, and with that synod passes the authoritative sentence' (Comm. on 1 Cor. v. 3). The older apostles had just as little official authority, just the same scope for moral influence. When Paul met them at Jerusalem in 51 A.D., they did not decide for the believers generally, but for themselves and their own course. They gave Paul and Barnabas 'the right hand of fellowship' that 'they should go unto the Gentiles.' Again, Paul felt he had to do, not with a board of officials, but with men whose past gave them great moral weight. In the second chapter of Galatians he never once uses the name 'apostle,' but he does mention 'the men of repute,' 'those who were reputed to be pillars.' Peter and John owed their position in great measure to their personal character, and James also to the fact that he was the brother of Jesus.

It may be objected that, anyhow, some official government must have been required in the early Christian gatherings, and that Paul implies that

there were persons who presided in the Thessalonian Church (1 Thess. v. 12). To which the answer is, 'That no doubt government existed, but that it was the government of those who were marked out for it by supernatural or natural gifts, not of officials.' We have seen already, that 'governments' are classed among the miraculous gifts of the Spirit. Further, the first converts, or those in whose house the church met (Rom. xvi. 5; 1 Cor. xvi. 19), would naturally direct the others, and take the lead in the congregation. 'I beseech you, brethren (ye know the house of Stephanas, that it is the first-fruits of Achaia, and that they have set themselves to minister unto the saints), that ye also be in subjection unto such, and to every one that helpeth in the work, and laboureth' (1 Cor. xvi. 15). Here the ministry or deaconship is one with the episcopate or superintendence. All is spontaneous, nothing official. The profusion of miraculous gifts prevented any desire for official teachers, and would have thrown them into the shade had they existed. Nor, some would add, could the apostles have thought of providing the churches with a regular government to last after their own death, though even so early a writer as Clement of Rome attributes this design to them. The fact, it is said, that the apostles, like the other Christians, confidently expected the coming of the Lord in their own time, proves this theory untenable.

Philippi was the earliest of the European churches, and there St Paul, towards the close of his life, does salute 'the saints' with the 'bishops and deacons.' Possibly, even then, these titles were beginning to be attributed, the former, to those who were the acknowledged leaders of the congregation; the latter, to those who devoted themselves to furthering and helping on its work. In later books of the New Testament canon, there is frequent mention of bishops or presbyters and deacons. And in the Acts the origin of these offices is traced back to the apostles themselves, and to the very beginning of the gospel. We are as yet, however, a long way from the Presbyterian system, because the office of teaching and preaching is quite separate from that of the presbyter. He was not a minister or preacher, but an 'overseer' or 'shepherd' of the church (Acts, xx. 28). He replaced the presbyters of the Jewish synagogue who presided over its discipline. And we are still further from diocesan episcopacy. Never once, from the beginning to the end of the New Testament, is 'a threefold ministry' of bishops, priests, and deacons so much as hinted at. On the contrary, bishop and presbyter are two words for the same office. The presbyters of Miletus (Acts, xx. 17) are also its bishops (verse 28); so are the presbyters in Crete (compare Titus, i. 5 with 7). The author of 1 Tim. iii. 7 having described the qualifications of a bishop, passes straight to those of the deacon, knowing nothing of any third office. True, it has been suggested—e.g. by Rothe (*Anfänge der Christ. Kirche*, p. 173, *seq.*) and by Bishop Lightfoot—that diocesan episcopacy may have sprung up at the close of the apostolic age. But it was unknown to Clement of Rome about 120 A.D. 'In his epistle,' says Bishop Lightfoot, 'there is no mention of episcopacy properly so called, for bishop and presbyter are still synonymous terms (see Clem. *Ep.* i. 44-47).' Precisely the same argument may be drawn from the 'Teaching of the Apostles' (xv.), and the Shepherd of Hermas (*Vis.* iii. 5). These authorities carry us well into the 2d century. An analogue to the diocesan bishop has been seen by some in the 'angels' of the Revelation. They are the guardian spirits of the churches, or possibly personifications of them, but not human rulers, as Bishop Lightfoot with others, before and since, has conclusively proved.

In the pastoral epistles, supposed by the more advanced critics to have been written in St Paul's name against the Gnostic heresies of the 2d century, we get closer to the point. There Titus and Timothy are certainly empowered to guard the faith, to appoint bishops or presbyters in every city, and to exercise authority over them. There is a tendency to identify the bishop or presbyter with the teacher or preacher, for the bishop is to be 'apt to teach' (1 Tim. iii. 2), but the identification is not yet complete, for it is taken for granted that only some bishops teach (1 Tim. v. 17). The recurrence of such phrases as 'sound doctrine,' and the position of Timothy and Titus, make us feel that we are already on the threshold of the Catholic Church with its rule of faith and its hierarchy. But even here much is lacking. Timothy and Titus are temporary delegates of the apostle, not diocesan bishops. It is in the Ignatian epistles that the Rubicon is passed, and here indisputably, in any case as early as the middle of the 2d century, the claims of bishops, in the modern sense, are insisted upon perpetually. It is useless to multiply quotations from writers of later date. By the time of Irenæus (190 A.D.), the diocesan episcopate was established throughout the Roman world. The old enthusiastic life of the early Christian meetings was replaced by the rule of the hierarchy. Even Ignatius had not reached the view which is familiar to Irenæus, and still more to Cyprian, that bishops are the successors of the apostles, and the channels through which primitive tradition is conveyed to successive ages. Thus, it is held by many, the Catholic Church arose, formed by a kind of necessity in the struggle against the exaggerated doctrines of the Gnostic sects, which threatened to dissolve Christianity in systems of fantastic and variable speculation. The canon or collection of New Testament books, with binding authority equal to that of the Old Testament, the episcopacy united with itself, the appeal to apostolic tradition, all arose from the same need, and on this triple foundation the Catholic Church was built.

Two other points, however, deserve notice. First, Jerome (died 420) (on Titus, i. 5; *Ep.* i. 46) and an earlier writer, whose works are printed with those of St Ambrose (on 1 Tim. iii. 8, 9, 10), perceived that bishops and presbyters had been originally one, and that the current distinction could claim no higher sanction than the custom of the church. Jerome's words, than which nothing can be more clear and strong, were incorporated in the *Decretum*, the earliest medieval collection of canon law (*Dist.* xciii. c. 24; xcv. c. 5), and thus all through the middle ages the schoolmen retained some idea of the real history of the office. Next, even in the 4th century, the church had not reached the modern principle that a bishop alone can confer valid orders. Thus, the Council of Ancyra in 314 A.D. (canon 13) assumes that presbyters may ordain presbyters with the bishop's sanction. The fathers of the council recognised of course the episcopal authority, but they did not attribute any supernatural efficacy to the imposition of episcopal hands.

The foregoing is a statement of the opinions, and the arguments on which these are based, held by the less conservative New Testament scholars both in England and Germany. Their argument has been given the more fully as still being much less known in England than the time-honoured High Church view, which has been for centuries the consistent theory of the whole Catholic Church. That theory of course is a perfectly simple and intelligible position, and the attitude of believers towards it depends mainly on the view they hold as to the literal interpretation of Scripture. For

apart altogether from the much wider and more difficult question, how far the general development in dogma of the whole body politic of the church is itself the outward evidence and expression of Christ's promised presence and guidance to the end of the world, the High Church theory of the apostolical succession of bishops—the representatives of the apostles, and through them of the Lord himself—finds strong support from the plain words of Scripture and the unforced exegesis of the same.

We must content ourselves with a brief summary of the later history of the office; and here it will be convenient to begin with the Roman Catholic and Eastern churches. There the duties and power of bishops remain much as they were in the middle of the 3d century, except so far as they have been curtailed by the rise of the papal power in the West, by the institution of Patriarchates and the interference of the state in the East. The Council of Trent requires the bishop to preach the word of God, and to maintain purity of doctrine among clergy and people. He has to superintend divine worship, and is bound to visit all the churches of his diocese at least once in every two years. He approves priests, and gives them faculties to hear confessions. He makes laws for his diocese, without power, however, to alter the common law of the church; decides ecclesiastical causes in the first instance; can suspend his clerical or excommunicate his lay subjects; he collates to all benefices, except those reserved to the pope; he directs the administration of temporal goods belonging to the diocese; he can dispense from his own laws, and, within certain narrow limits, from the law of the church. Such is the jurisdiction or ruling power of a bishop, but he is by no means supreme or unfettered even in his own diocese. He is subject by divine law to the councils of the church, and, as Roman Catholics believe, to the pope, and by ecclesiastical law he is in subordination to patriarchs, metropolitans, &c. In respect of orders—i.e. in power of consecration and the like—he has no superior, nor do pope or patriarch pretend to higher power than that of a simple bishop. He alone can consecrate other bishops, and ordain priests, and he alone, according to the Roman Catholic theory, is the ordinary minister of confirmation.

He is now addressed in the Latin Church as 'Most Illustrious and Reverend Lord,' though once titles which have become peculiar to the pope—e.g. 'Most Holy, Most Blessed Lord,' 'Your Holiness,' 'Servant of the Servants of God,' were common to mere bishops. His insignia are the ring, pectoral cross, episcopal throne, mitre, pontifical vestments, gloves, and sandals.

Bishops were in the earliest ages chosen by the people, subject to a veto by the bishops of the province (Cyprian, *Ep.* lxviii.). In 325 A.D. the first Nicene Council (canon 4) recommended appointment by the provincial bishops, subject to confirmation of their choice by the metropolitan. Greek canonists understood this canon as annulling the old form of popular election, and at present the Greek orthodox bishops are nominated by the patriarch, though in Russia the final nomination rested with the tsar. In the West the canon was understood to leave the popular rights of election unimpaired, merely requiring the presence of the bishops of the province, and confirmation by the metropolitan. In the 11th century the right of election passed to the Cathedral Chapter, and the pope gradually engrossed the sole right of confirmation, till at last Clement V. and his successors claimed the right of nomination also, first in certain cases, and then absolutely. Since then the pope has restored the right of election to the chapters in certain sees and countries. In others the head of the state

nominates. The election is purely papal in Belgium, also in Holland, Great Britain and Ireland, North America, and other Protestant countries. A right of recommendation, however, is conceded to the Roman Catholic chapters in Belgium, Holland, and England, to chapters and parish priests in Ireland, to the bishops of the province in North America. The right of consecration, which used to belong to the metropolitan and two other bishops, is now reserved to the pope, or a bishop nominated by him. There are about 200 archiepiscopal and 900 episcopal sees in the Roman Catholic Church. In Ireland there are 4 archbishops, 24 bishops; in England and Wales, 4 archbishops, 13 bishops; in Scotland, 2 archbishops, 4 bishops. Altogether there are about 200 Roman Catholic sees in the British empire. In the United States there are over 100. Besides these, there are the titular bishops, till the pontificate of Leo XIII. called bishops *in partibus infidelium*. They have received episcopal consecration, but have no regular jurisdiction. They assist some other bishop, or are delegates of the pope where the hierarchy is not established.

Passing to the Reformed churches, we find the theory of the Anglican much the same as that of the Roman episcopate, except that in England the authority of the crown has replaced that of the pope. The Anglican bishop is said, though the statement is disputed by Roman Catholic controversialists, to descend in direct line of consecration from his predecessors in the middle ages. He alone can ordain, confirm, and consecrate churches. He institutes to benefices and licenses curates; he has the right to preach throughout the diocese, to inspect the churches and churchyards. He can withdraw the licenses of curates, who may, however, appeal to the metropolitan. He is *ex officio* president in the Consistorial Court. With regard to criminous clerks his power is very limited, not only because the final decision rests with the King in council, but also because the English law protects the interests of the inferior clergy with a zeal unknown to the modern canon law of the Roman Church. Thus, whereas the Council of Trent permits a bishop to decide in cases of certain grave charges against clerks 'without formal trial, having simply ascertained the truth of the fact,' an Anglican prelate has no such power. He may institute a commission of inquiry, and decide the case with three assessors, one of whom must be a barrister, or he may at once prosecute in the Superior Court. If he himself passes sentence, an appeal lies to the Court of Arches in the province of Canterbury, to the Chancery in the province of York, and ultimately to the Privy-council. If a bishop refuses to institute a clerk to a benefice, the appeal is first to the archbishop and then to the Privy-council. There are in England two archbishops and about forty bishops, about as many bishops suffragan and assistant bishops, the archbishops and twenty-four of the bishops having seats in the House of Lords. There are two archbishops and eleven bishops in the disestablished Church of Ireland; seven bishops in the Episcopal Church in Scotland, one of whom is called Primus; one archbishop and six bishops (including the archbishop) in the disestablished Church in Wales (including Monmouth); about a hundred and twenty-five colonial and missionary archbishops and bishops; and about a hundred in the Episcopal Church of the United States.

The early Lutherans were singularly moderate and rational in their attitude to episcopacy. They denied its divine institution, but they were quite willing to tolerate it when circumstances made it expedient to do so. In Germany the name of bishop fell into disuse, or was retained as a merely civil title, or revived for a short time, and then

allowed to drop; and the Lutheran superintendent is a mere shadow of a medieval bishop. On the other hand, the Lutheran churches of Denmark and Scandinavia have always been episcopal. There are eight bishops in Denmark, nominated by the crown; one archbishop and eleven bishops in Sweden; six bishops in Norway, which last are chosen by the clergy; and one bishop in Iceland. These Lutheran bishops have the sole right of ordination, but in Sweden their disciplinary power is exercised in union with a consistory, the majority of whose members are laymen.

For the early history of the office, see Lightfoot on Philippians; Rothe, *Anfänge der Christlichen Kirche*, p. 261 seq.; Ritschl, *Entstehung der Altkatholischen Kirche*, p. 399 seq.; Baur, *Christenthum und Kirche der ersten drei Jahrhunderte*, p. 260 seq.; Hatch, *Organisation of the Early Christian Churches*; Weizsäcker, *Apostolisches Zeitalter*, p. 606 seq. The historical canonists of the Roman Catholic Church, such as Thomassin, afford abundant information on the episcopate in later patristic and medieval times. Dr Wordsworth's *Theophilus Anglicanus* and Gore's *Ministry of the Christian Church* are statements of the High Church theory; Dollinger's *First Age of the Church* treats the subject from the Roman Catholic standpoint. See also 'Episcopacy' by Darwell Stone in Hastings's *Encyclopædia of Religion and Ethics* (1913); the great *Catholic Encyclopædia* (15 vols. 1907-12); and for the Protestant position generally, the Hauck-Herzog *Real-encyclopædie für Protestantische Theologie* (1896-1909). See also the articles in this work on APOSTOLICAL SUCCESSION, ARCHBISHOP, ENGLAND (CHURCH OF), ORDERS, PRIEST, ROMAN CATHOLIC CHURCH. For Celtic episcopacy, see the sections on church history in the articles IRELAND and SCOTLAND.

Bishop, SIR HENRY ROWLEY, composer, was born in London, 18th November 1786. His principal musical instructor was Francesco Bianchi, an opera-composer settled in London. In 1806 Bishop was appointed composer of ballet music at the Opera. Among his 88 operatic entertainments were *Guy Mannering*, *The Miller and his Men*, *Maid Marian*, *Native Land*, and *The Virgin of the Sun*—all less remarkable for originality than for their flowing melodies and animated style. The opera *Aladdin* (1826) was a failure. The famous glee 'The Chough and Crow' is his; many popular songs, such as 'Should he Upbraid,' 'My Pretty Jane,' are by him; and his, too, probably, is 'Home, Sweet Home' (see PAYNE). From 1810 to 1824 he was director of the music at Covent Garden Theatre, from 1825 to 1830 at Drury Lane, and for three years more at Vauxhall Gardens. One of the first directors of the Philharmonic Society, he for nine years conducted the concerts of Ancient Music. From 1841 to 1843 he was Reid professor of Music in the university of Edinburgh. In 1842 he was knighted, and in February 1848 elected professor of Music in the university of Oxford. In his later years he was in very necessitous circumstances. He died of cancer, 30th April 1855. See *Life* by Richard Northcott (1911).

Bishop, ISABELLA. See BIRD.

Bishop-Auckland, an urban district in the county, and 9½ miles SW. of the city, of Durham, stands on an eminence 140 feet above the confluent Wear and Gaunless. Its abbey-like palace of the bishops of Durham was founded about 1300 by Bishop Antony Bek, and rebuilt by Bishop Cosin shortly after the Restoration. The town-hall is a handsome edifice of 1863, with a spire 100 feet high. There are engineering-works and large neighbouring collieries. Pop. (1851) 4400; (1881) 10,097; (1911) 13,834; (1921) 14,294.

Bishop's Cap, a North American and Japanese genus (*Mitella*) of Saxifragaceæ, with small greenish flowers in one-sided inflorescences.

Bishop's Castle, a municipal borough of Shropshire, 22 miles SW. of Shrewsbury. Till 1832 it returned two members to parliament. It is irregularly built on a hill slope. The bishops of Hereford had formerly a castle here. Pop. 1300.

Bishop's Falls, on the Exploits River, Newfoundland, 14 miles from its mouth, has great pulp-mills and paper-making works.

Bishop-Stortford, a town of Hertfordshire, on the Stort, 12 miles ENE. of Hertford. It chiefly consists of two streets in the form of a cross. It carries on a trade in grain and malt. Bishop-Stortford was in Saxon times the property of the bishops of London. Pop. 9000.

Bishop's Waltham, a town of Hampshire, 9½ miles SE. of Winchester. It has been immemorially the property of the see of Winchester. There are remains of a castle, built in 1135 by Bishop Henry de Blois, and reduced to ruins during the civil war of the 17th century.

Bishopwearmouth. See SUNDERLAND.

Bishopweed, or GOUTWEED, also Goatweed, or Herb Gerard (*Agropodium Podagraria*), an umbelliferous weed common in hedges and grass plots, and exceedingly difficult of extirpation on account of its creeping rhizomes. It is eaten by cattle, and the leaf-stalks were formerly boiled and eaten as greens. The root-stock was long esteemed as a remedy for gout.

Biskra, a town of Algeria, 150 miles SW. of Constantine by rail, in an oasis watered by the Wady Biskra and by springs. It was known to the Romans as *Zaba*, and under the Moors it became a large town. It is now a favourite health-resort for Europeans. A railway runs south to Tougourt. At Biskia in 1663 some 71,000 persons died of the plague. Pop. 5000.

Bisley, a village of Surrey, 4 miles NW. of Woking; to Bisley Common were removed in 1890 the meetings of the National Rifle Association, and Bisley became 'the new Wimbledon.'

Bismarck, capital of North Dakota, is on the east side of the Missouri, here crossed by the Northern Pacific Railway on an iron bridge. Large quantities of goods are sent up the Missouri, which is navigable 1200 miles above Bismarck. Great sums have been spent by the government in digging out the sand-bars from the river above the town. Pop. 7000.

Bismarck Archipelago, the name officially given by Germany to New Britain, New Ireland, New Hanover, and several smaller adjoining islands in the South Pacific. In 1884-1919 they were a German dependency, now, with the rest of German New Guinea, under an Australian mandate. See NEW BRITAIN, &c.

Bismarck-Schönhausen, OTTO EDUARD LEOPOLD, PRINCE VON, DUKE OF LAUENBURG, chancellor of the German empire and foremost statesman of his time, was born 1st April 1815, at Schönhausen in Brandenburg, of an old family distinguished both in war and statesmanship. Bismarck received his university education at Göttingen, Berlin, and Greifswald, where he studied law and agriculture, but became more distinguished as a swordsman than as a reading man. After finishing his studies, he lived for a time on his estates. Before 1847 he was little heard of, but about that time he began to attract attention in the new Prussian parliament as an ultra-royalist, and a fierce but unsuccessful opponent of the constitutional demands resulting from the March revolution of 1848. He opposed the scheme of a German empire as proposed by the Frankfurt parliament of 1849, for the reason that

the title to the imperial dignity offered to the king of Prussia was merely based on the popular will and not on the concurrent assent of the German sovereigns as well. His diplomatic career commenced in 1851, when he was appointed Prussian member of the resuscitated German diet of Frankfurt. Here he began to manifest that zeal for the interests and aggrandisement of Prussia, which thereafter undeviatingly guided him, often regardless of the means. In the diet he gave open expression to the long-felt discontent with the predominance of Austria, and demanded equal rights for Prussia. At Frankfurt he remained till 1859, when he beheld in the approach of the Italian war an opportunity of freeing Prussia and Germany from the injurious dominance of Austria; but his views of energetic action being not yet shared by the cautious and pacific prince-regent, Bismarck was meanwhile recalled from the diet and sent as minister to St Petersburg. In the spring of 1862 King William, on the urgent advice of the Prince of Hohenzollern, transferred Bismarck as ambassador to Paris, in order to give him an insight into the politics of the Tuileries, before intrusting him with the direction of affairs at home. During his short stay at Paris Bismarck visited London, and had interviews with the leading politicians of the time, including Lord Palmerston and Mr Disraeli. In autumn, when the king's government could not obtain the consent of the lower house to the new military organisation, Bismarck was recalled, to take the portfolio of the ministry for foreign affairs, and the presidency of the cabinet. Not being able to pass the reorganisation bill and the budget, he closed the chambers (October 1862), announcing to the deputies that the king's government would be obliged to do without their sanction. Accordingly, the army reorganisation went on; and the next four sessions of parliament were closed or dissolved in the same way, without the government obtaining, or even caring to obtain, the sanction of the house. When the 'Conflict Era,' as it was called, approached a crisis, the death of the king of Denmark re-opened up the Schleswig-Holstein question, and excited a fever of national German feeling, which Bismarck was adroit enough to work so as to aggrandise Prussia by the acquisition of the Elbe Duchies, and reconcile his opponents to his high-handed policy by pointing to the success of the newly-modelled army. Throughout the events which ended in the humiliation of Austria at the battle of Königgratz (1866), and the reorganisation of Germany under the leadership of Prussia (see GERMANY), Bismarck was the guiding spirit; and such is the magic of success, that, from being universally disliked, he now became the most popular man in Germany. It was Bismarck that negotiated the neutralisation of the Luxemburg territory (1867).

The action of France in regard to the candidature of Prince Leopold of Hohenzollern for the throne of Spain gave Bismarck the opportunity of carrying into action the intensified feeling of unity amongst Germans. During the war of 1870-71, Bismarck was the spokesman of Germany; he it was that in February 1871 dictated the terms of peace to France. Having been made a count in 1866, he was now created a prince and chancellor of the German empire. From the peace of Frankfurt (10th May 1871) the sole aim of Bismarck's policy, domestic and foreign, was to consolidate the young empire of his own creating, by rendering its institutions more beneficent, authoritative, homogeneous, and stable; and again by securing it, through alliances and political combinations, against attack from without. Thus, conceiving the unity of the nation and the authority of its government to be endangered by the Church of Rome, and

its doctrines of Papal Infallibility, he embarked on that long and bitter struggle with the Vatican, called the Kulturkampf, in the course of which the Imperial and Prussian parliaments passed a series of most stringent measures (Falk or May laws) against the Catholic hierarchy. But Bismarck had underrated the resisting power of the Roman Church, and motives of political expediency gradually led him to modify or repeal the most oppressive of the anti-papal edicts, leaving the Catholics virtual masters of the field. Otherwise, his domestic policy was marked, among other things, by a reformed coinage, a codification of law, a nationalisation of the Prussian railways (as a preliminary step to Imperial state lines), fiscal reform in the direction of making the empire self-supporting (i.e. independent of 'matricular contributions' from its component states), repeated increase of the army and the regular voting of its estimates for seven years at a time (Military Septennate), the introduction of a protective tariff (1879), and the attempt to combat social democracy and socialistic agitation by means at once repressive and remedial—among the latter being a lightening of the burden of direct taxation, the insurance of working men against suffering from accidents, indigence, and old age, with other economic experiments, which have caused Bismarck to be called the greatest state socialist of the age. With a view to improve the finances of the empire, Bismarck repeatedly tried to establish various government monopolies, of tobacco, &c., but without success.

In 1884 Bismarck inaugurated the career of Germany as a colonising power, a new departure which brought him into sharp but temporary conflict with the England of Mr Gladstone. For the rest, his foreign policy aimed principally at isolating France and rendering her incapable of forming anti-German alliances. On the other hand, he gradually combined the central powers of Europe into a peace-league, aiming at counteracting the aggressiveness of Russia and France, separately or combined, on the Danube or the Rhine. The nucleus of this peace-league was formed in 1879 by the Austro-German Treaty of Alliance (published February 1888), which Italy joined in 1886. It entitled Bismarck to be called the 'Peace-maker' of Europe, a character he first acquired when, as 'honest broker' between Austria and Russia, he presided over the Berlin Congress in 1878. The phrase, 'man of blood and iron,' is based on 'the Iron Chancellor's' own use of the words in a speech in 1862.

Bismarck's life was repeatedly threatened, and twice actually attempted—once at Berlin in 1866, just before the Bohemian campaign, by a crazy representative of popular dissatisfaction with Bismarck as champion of absolutism and fratricidal war; and again in 1874 at Kissingen, by an Ultramontane tinsmith named Kullmann. In 1885 Bismarck's 70th birthday was celebrated as a great national event. As a statesman he was imperious yet prudent, jealous, vindictive, and even unscrupulous—faults that sprang from his feivd patriotism; but in private life he could be genial, witty, and entertaining. He was tall and massive in person, fair and fresh of complexion, and quiet and cultured in manner. Though no orator, in public speeches he wielded the mother-tongue with trenchant vigour (see GERMANY); and he spoke French, Russian, and English with facility. Soon after the accession of William II., the relations between the veteran and his young master became strained. The emperor resented the chancellor's independent and masterful ways, and Bismarck felt driven to resign in March 1890, retiring with the title of Duke of Lauenburg. He now became, and—though there was a formal reconciliation in

1894—continued, a caustic and inconvenient critic of the emperor, the successive chancellors, and the new polity generally. In 1895 his birthday was again a national celebration, though the Reichstag refused to present an address of congratulation. Bismarck died 30th July 1898, and an autobiography was printed immediately after.

See books by Busch (1890-98), Blum (1884-95), Heyck (1904), and in English by Lowe (1888-96), Headlam (1899), Whitman (1902); his love-letters (trans. 1901), his political correspondence, and his speeches.—His son, Count Herbert Bismarck (1849-1904), was foreign secretary under his father.

Bismarck, FRIEDRICH, COUNT VON (1783-1860), born at Windheim in Westphalia, spent most of his life in the Württemberg army, but from 1804 to 1807 was in the English service. He wrote on cavalry tactics and organisation.

Bismuth (sym. Bi, eq. 208) is a brittle metal, white with a faint red tinge. It is found native in Cornwall, France, Peru, Siberia, &c., but is mostly obtained from Saxony. It exists also in combination with oxygen, carbonic acid, lead, tellurium, &c., but the native (impure) metal is preferred. The ore is placed in inclined iron tubes, and heat applied, when the metal melting and partly volatilising, runs down to the receivers, and when transferred to moulds, solidifies with a crystalline texture. When pure, it crystallises more readily than any other metal; and it exhibits the singular anomaly, that when it has been exposed to great pressure its

Bismuth:

a, example of native bismuth from Redruth, in Cornwall;
b, crystal of bismuth

density becomes less. It may be distilled at a high temperature, and repels a magnet more than any other metal. Heated in the air, it burns with a blue flame, forming yellow fumes of oxide. Bismuth unites readily with other metals, forming Alloys (q.v.). The most remarkable of these is called fusible metal, consisting of 2 of bismuth, 1 of lead, and 1 of tin, the melting-point of which is 200·75° F. (93·75° C.), or 12° below the boiling-point of water. Spoons made of this alloy, therefore, readily melt when placed in boiling water; a favourite trick with amateur conjurers. A still more fusible metal is obtained by the addition of mercury, and this is used in forming moulds for toilet-soaps or in taking casts. Bismuth has a specific gravity of 9·83, and melts at 507° F. (264° C.).

Bismuth forms several compounds of service in the arts and in medicine; it combines with oxygen to form several oxides, of which the trioxide, Bi₂O₃, is the most important. It may be prepared by boiling together a solution of the subnitrate of bismuth, BiONO₂, and caustic soda, NaHO, when the oxide, in combination with water, is thrown down, and nitrate of soda remains in solution. It is employed in the porcelain manufacture as an agent for fixing the gilding, and for increasing the fusibility of fluxes, at the same time neutralising the colours which are often communicated by them. The ternitrate of bismuth is prepared by acting upon the metal bismuth with a mixture of one part of commercial nitric acid and

one part of water, and applying heat. The subnitrate or basic nitrate of bismuth receives the names of *Pearl White*, *Pearl Powder*, *Blanc de Fard*, and *Blanc d'Espagne*. It is used as a cosmetic, but is apt to become gray in tint, and even brown or black, when sulphuretted hydrogen, often evolved from sewers, cesspools, and drains, comes in contact with it. The subnitrate and subcarbonate of bismuth are used in medicine as very soothing, feebly astringent sedatives when applied to irritated mucous membranes, and are of great value in various forms of stomachic disease; while externally they are used as an application to scrofulous sores. The citrate of bismuth in combination with ammonia being very soluble, is more rapid and irritant in its action than the soluble salts last mentioned, but is of special use in cases of relaxation with excessive discharge. Bismuth salts sometimes contain arsenic, and must be used with caution. The 'bismuth breath' is a peculiar garlicky odour often felt in the breath of those who have taken bismuth preparations for some time. The cause of this is not clearly known, although at various times the presence of arsenic or tellurium as impurities has been blamed for it; but it would seem that it may be produced even when these are absent.

Bison (Lat. ; Old High Ger. *Wisund*), a genus of wild cattle, represented by two rapidly disappearing species in Europe and America. The European Bison (*Bos europæus* or *Bonassus*), wrongly confounded with the Aurochs (*Urus*), was common in Europe in Roman times, but has gradually been all but exterminated. It only persists in a dwindling herd in the wilds of the Ural and Caucasus; the last in Lithuania was shot in 1919. The bison measures about 10 feet in length, stands about 6 feet high, and is extremely strong, especially in its fore-parts. Old bulls can knock down trees 5 or 6 inches in diameter, and can readily cope with wolf or bear. The most striking differences between a bison and an ox are the hump just behind the neck, the broader convex forehead, the longer limbs, the shaggier head and shoulders. There are also internal differences, such as the presence of an additional rib. The hump is due to the long spines of the backbone bodies in that region, and to the enormous muscles working the head. The horns are short and very far apart, a little curved inwards at the point, and fixed not at the ends of the top-most ridge of the head, but considerably in front of it. The long shaggy hair on head and breast is of a dusky brown colour, and is cast in summer. The females are not so large as the males, nor do they exhibit the same shagginess of the fore-parts. The bison is the largest quadruped now existing in Europe, although within the historic period there existed along with it an even larger ox (*B. primigenius*), the *Urus* of the ancients, abundant in the time of the early Roman emperors. The ancient *Bonassus* was apparently the still extant bison. The food of the bison consists of grass and brushwood, and the leaves and bark of young trees. Its cry is peculiar, 'resembling a groan or a grunt, more than the lowing of an ox.' It does not attain its full stature till after its sixth year, and lives for about thirty or forty years. The period of gestation appears to be the same as that of the ox. The bison has never been reduced to subjection by man, and the domestication even of individuals taken young, has been very partial. It generally shows a great aversion to the domestic ox. The bison is generally very shy, and can only be approached from the leeward, its smell being very acute. It is easily provoked, and is not approached without danger. It runs very swiftly, although it cannot long continue its flight, galloping with its head very low, so that the

hoofs are raised higher than the head. Few authorities derive any of the domestic breeds of cattle from the bison, though Wilckens proposes this theory. It is usually supposed, however, that all have descended from *B. primigenius*.

There is no historical record that the bison ever existed in Britain; but remains of this, or of a very closely allied species, are found in Pliocene freshwater beds in several parts of England, as well as on the continent of Europe. The commonest fossil species is *B. prisus*, but other closely related forms are known (*B. svalensis*, *latifrons*, *antiquus*).

The American Bison (*B. Americanus*) is interesting as the only living species of the ox family indigenous to America, except the Musk Ox (q.v.) of the subarctic regions. It is commonly called *Buffalo* by the Anglo-Americans, but must be distinguished from the true Buffalo (q.v.). The bison was within recent times very abundant in America, especially in the prairies beyond the Mississippi, and from 63° N. lat. to New Mexico. Even in the 19th century it was still found in Ohio. In 1886 the Smithsonian Institute sent out emissaries to procure a few skins and skeletons. It was found none were left save in the Yellowstone Park, and a few in Montana and Texas. In 1850 there may have been 20,000, in 1910 perhaps 2000—mainly in the Yellowstone and Montana reserves,

American Bison.

two Canadian reserves, and in some three or four private herds; in 1920, 6000 in Canada (including a newly discovered herd of 1000 in the Mackenzie basin), and 3400 in U.S. The Wainwright herd (Alberta) so increased that in 1923 the Canadian Government ordered the slaughter of 2000, and it was decided to transport 10,000 more to a new reserve at Fort Smith on the Slave River. They used to congregate in large herds, and when migrating travelled in solid columns of thousands and tens of thousands, which could hardly turn or arrest their progress for the pressure of the masses from behind on those in front. The Indians shot them in the chase, frightened them over precipices, and in other ways killed them in enormous numbers.

The differences between the American and European bison are quite immaterial. The former is slightly smaller, shorter in limb, and blunter in horn. The fore-parts are still more shaggy, and retain most of their shagginess in summer. In their palmy days at least, the male and female American bison lived apart in separate herds, and the bulls, though usually pacific, were dangerous at the breeding or fighting time. The grizzly bear is said to be the only animal which could dare singly to attack a bison.

The economic importance of the bison was once great. The flesh, like coarse-grained beef, is tender and juicy, while the tongue and marrow bones and hump were specially prized. The hump formed pemmican; the fat, tallow; the skins, clothing or tent and canoe covers; the hair, cloth; and the dried droppings, fuel. The 'cattalo' (a cross with domestic cattle) is bred for beef and 'robo.'

See Allen's monograph on American bison (1876), Hornaday's *Extirmination of the American Bison* (1889), Roosevelt and Grinnell's *Big Game Hunting* (1893), E. Thompson Seton's *Life-histories of Northern Animals* (1910); and for the European bison, Prince Demidoff's *Hunting Trips in the Caucasus* (1898).

Bissagos Islands, a group of small volcanic islands, about 30 in all, off the west coast of Africa, opposite the mouth of the Geba River, and belonging to Portuguese Guinea. The climate is pestilential to Europeans.

Bissão, an island and Portuguese station closer to the African coast than the Bissagos.

Bissen, WILHEM, a Danish sculptor, was born in Sleswick in 1798, and from 1823 to 1833 studied in Rome under Thorwaldsen, who, in his will, commissioned him to complete his unfinished works. In 1850 he was made director of the Academy of Arts, Copenhagen, where he died 10th March 1868. Among his masterpieces are the 'Valkyrie,' 'Cupid sharpening his Arrow,' and 'Moses'; his 'Orestes,' and a frieze 134 feet long, perished in the burning of the Christiansborg at Copenhagen (1884).—See the life by Plon (2d ed. Paris, 1871).

Bistort (*Polygonum bistorta*), a perennial plant, 1 to 1½ feet high, with a simple stem, ovate subcordate and wavy leaves, the radical leaves tapering into a long footstalk, and one dense terminal cylindrical spiked raceme of flesh-coloured flowers. The root is about the thickness of the little finger, blackish-brown externally, reddish within, and tortuous (whence the name *bistort*, and probably also the other popular name of Snake-root). The whole

Bistort (*Polygonum bistorta*):

a, b, c, flowering stem and root stock; d, a flower; e, a fruit.
(From Bentley & Trimen)

plant is astringent, containing much tannin; the root is one of the strongest vegetable astringents, and was formerly much employed in medicine, both internally and externally, in hemorrhages and many other complaints. Bistort is a native of meadows in Europe, and is found in Britain, but is by no means common. In times of famine the root has been used after washing as a source of starchy food. See POLYGONACEÆ.

Bistre is a pigment of a warm brown colour, prepared from soot, especially the soot of beech-wood.

Bistritza, or BISTRITZ, a town of Transylvania, beautifully situated on the Bistritza River, 60 miles NE. of Klausenburg; pop. 10,000.

Bisutun. See BEHISTUN.

Bit. See BRIDLE.

Bitche (Ger. *Bitsch*), a town of Lorraine, in a wild and wooded pass of the Vosges, 49 miles NNW. of Strasburg by rail. Its citadel crowns a precipitous and isolated rock in the middle of the town. The Prussians under the Duke of Brunswick attempted to surprise it in 1793, but failed. It resisted the Germans for seven weeks in 1815, and did not surrender till three weeks after the close of the war of 1870-71.

Bithur, a town in India on the Ganges, 12 miles NW. of Cawnpore. It is particularly devoted to the worship of Biahma, who is believed to have celebrated the completion of creation by a horse-sacrifice here. The stronghold of the infamous Nana Sahib, it was captured by Havelock in 1857.

Bithynia, an ancient division of Asia Minor, separated from Europe by the Propontis (Sea of Marmora) and the Bosphorus, and bounded N. by the Euxine. It contained the famous Greek cities or colonies of Chalcedon and Heraclea; and at later periods, Nicomedia, Nicæa, and Prusa were flourishing cities of Bithynia. The Bithynians were supposed to be of Thracian origin. The country was subdued by the Lydians, and afterwards became a part of the Persian dominion under Cyrus. But during the decline of the Persian empire, it became an independent kingdom under a dynasty of native princes, who made Nicomedia their capital. The last king, Nicomedes III., made the Romans his heirs, and with a large addition from the Pontic kingdom, Bithynia became a province of the empire (74 B.C.). Under Trajan, Bithynia was governed by Pliny the Younger. The Emperor Diocletian made Nicomedia his habitual residence. In 1298 Osman the Turk broke into the country; and in 1326 Prusa, or Brusa, then the chief town of Bithynia, became the capital of the kingdom of the Osmanli.

Bitlis, a town of Armenia, 120 miles SE. of Erzerum, 5470 feet above the sea, in a deep ravine traversed by the river Bitlis, one of the head-streams of the Tigris. Bitlis is a straggling, irregular place, covering a large surface of ground, and surrounded by bare limestone mountains, rising 2000 feet above the valley, which is filled with orchards and gardens, and watered by numerous streams and springs. The population numbers about 40,000, mostly Mohammedans. The Persians defeated Solyman the Magnificent near Bitlis in 1554. The Russians took it in 1915 and 1916.

Bitolia, or BITOLJ. See MONASTIR.

Bitonto (ancient *Butuntum*), a town of Italy, 10 miles WSW. of Bari. It is situated in a fruitful plain about 5 miles from the sea, is well built, and has a fine cathedral and a theatre. In the vicinity the Spaniards defeated the Austrians in 1734. Pop. 35,000.

Bittenfeld. See HERWARTH.

Bitter Apple. See COLOCYNTH.

Bitter Cress. See CRESS.

Bitter King (*Soulamea amara*), a shrub or small tree of the natural order Simarubaceæ (see QUASSIA), a native of the Moluccas and Fiji Islands, which has received its name from its intense bitterness.

Bittern (*Botaurus*), a genus of birds nearly related to the herons (Ardea). Bitterns are chiefly distinguished from herons by the long, loose plumage on the front and sides of the shorter neck, and by the greater length of their toes, the middle one being as long as the shank. The feathers can be erected so as greatly to increase the apparent size of the bird. The back of the neck is downy or almost bare.

They are almost all solitary birds, inhabiting reedy and marshy places, where they lie hid during the day, and will almost allow themselves to be trodden upon before they take wing. They feed during the night, and then often rise to a great height in the air, making the night noisy with loud resounding cries. Their food consists chiefly of frogs, and partly, also, of fish, lizards, water-insects, &c., and even of small birds and quadrupeds. The claw of the middle toe is serrated on the inner edge, probably to aid in securing slippery prey. The Common Bittern (*B. stellaris*) is distributed very widely over the Old World, being found in almost

The Common Bittern.

all, at least of the temperate, parts of Europe, Asia, and Africa, which are sufficiently marshy for its manner of life. It is now rare in Britain, owing to drainage; but was formerly more common, and in the days of falconry, was carefully protected on account of the sport which it afforded. Its flesh also was in high esteem, not being rank and fishy, like that of the herons generally. In size it is rather less than the common heron; the sharp bill is about 4 inches long, the feathers on the crown of the head are greenish black, and the plumage in general of a dull yellow colour, beautifully and irregularly marked and mottled with black and reddish brown.

The bittern makes a rude nest of sticks, reeds, &c. in its marshy haunts, and lays four or five greenish-brown eggs. It has a peculiar bellowing or booming cry, especially insistent at the breeding-season. This has earned for it such English provincial names as Mire-drum, Bull of the Bog, &c., and many of its appellations in other languages, perhaps even its name Bittern (*Bitour*, *Botur*, *Botaurus*). Some naturalists used to assert that the booming cry of the bittern was produced by the bird inserting its bill into a reed; that notion, however, has long since been exploded. The animal is sluggish, and its flight is neither swift nor long sustained. When assailed, it fights desperately with bill and claws; and it is dangerous to approach it incautiously when wounded, as it strikes with its long sharp bill, if possible, at the eye.—The Little Bittern (*B. minutus*) is common in some parts of Europe, but rare in Britain. Its whole length is only about 13 inches. The American Bittern (*B. lentiginosus*), a species almost equal in size to the common bittern, and very similar to it in habits and voice, has occasionally been shot as a straggler in Britain. It is common in many parts of North

America, migrating northward and southward, according to the season. The crown of the head is reddish brown, and the colours and markings of the plumage differ considerably from those of the common bittern. The Least Bittern (*B. exilis*) is another North American species, of very small size, which is also migratory, and somewhat social in its habits. The Australian Bittern (*B. australis*) is generally diffused throughout Australia, wherever marshes or sedgy rivers occur. In habits it closely resembles the bittern of Europe. The head and upper parts generally are purplish brown, except the wings, which are buff, conspicuously freckled with brown; the throat, breast, and belly mottled brown and buff.

Bittern. BITTER LIQUID, or SALT OIL, is an oily liquid obtained during the preparation of common Salt (q.v.). When the mother-liquor of the evaporating pans ceases to deposit crystals of common salt, there is left behind in the boilers the material called bittern. It consists principally of a strong solution of common salt, along with the chlorides of magnesium and calcium, to which the bitter taste is due; but it also contains the bromides of sodium and calcium, which are valuable sources of the element Bromine (q.v.). The bittern obtained from the salt-works at Epsom was at one time the source of the sulphate of magnesium (hence called Epsom salts), but at present this salt is obtained in other ways.

Bitter Root Mountains. See ROCKY MOUNTAINS.

Bitters are prepared from an infusion of herbs containing bitter principles. Formerly the name was limited to a favourite household remedy prepared from the Garden Angelica (see ANGELICA). The roots or seeds, or both, were placed in water, and allowed to simmer for several days, when the bitter infusion was strained off for use. Coincident with the disuse of these bitters, the term assumed a wider significance, embracing all bitter infusions, many of them containing a large element of alcohol, with distinctive names such as Angostura, Quassia, Gentian, or Orange Bitters. An aerated beverage, called tonic bitters, flavoured with chiretta, calumba, quassia, or gentian, is esteemed by many. The medicinal properties of bitters are mainly those of a mild tonic and pungent aromatic stimulant, and hence they are serviceable as a stomachic in cases of weakness of the digestive organs. When taken in excess, the more powerful of them are apt to do more harm than good, the tone of the stomach being undermined by the excessive stimulation. The most widely used bitter is that of the hop, to which, in part at least, are due the tonic properties of beer. The medicines known as hop bitters must not, however, be supposed to derive any virtues they possess from the hop, their nature being rather that of a purgative.

Bittersweet, or WOODY NIGHTSHADE (*Solanum dulcamara*), a plant found in hedges and thickets in Britain, and throughout the palaearctic region, also introduced into North America. The root is perennial and creeping; the annual stems climbing and trailing, 4 to 6 feet in length; the leaves acuminate with 2 lateral pinnae, the upper halbert-shaped; the flowers purple, in drooping corymbs, much resembling those of its congener, the potato, but much smaller, followed by ovate red berries of tempting appearance, which, although by no means approaching in poisonousness to those of the true nightshade (see BELLADONNA), contain an apparently variable quantity of alkaloid, and seem sometimes to have been the cause of accidents, particularly to children; although some physiologists have administered it without bad

effects. The twigs, collected in autumn after the leaves are fallen, are still occasionally used in medicine, a decoction being given in rheumatic or

Bittersweet (*Solanum dulcamara*):
a, a flower; b, fruit.

cutaneous affections. It is in the stems rather than in the fruit that the peculiar succession of tastes, to which the plant owes its name, is best observed.

Bitter Vetch. See OROBUS.

Bitterwood, a name given to certain species of *Xylopia*, a genus of Anonaceæ, trees and shrubs remarkable for the bitterness of their wood, particularly the West Indian *X. glabra*. Furniture made of this wood is safe from the attacks of insects. —The fruit of some of the species, particularly *X. sericea*, is highly aromatic and pungent like pepper. *X. sericea* is a large tree, a native of Brazil; its bast tissue is used for making cordage, which is excellent.

Bitterwood is also the name of *Picrorena excelsa* (formerly *Quassia excelsa*), a tree of the natural order Simarubaceæ (q.v.), a native of Jamaica, the wood of which is now alone used in medicine, as *Quassia* (q.v.), owing to the scarcity of the *Quassia amara*, to which the name was first given. It is, botanically, very nearly allied to the true quassia, and possesses very similar properties, containing the crystallisable bitter principle called Quassite or Quassin. The wood, which is intensely bitter, is a very useful stomachic and tonic; an infusion of it is a well-known and useful fly-poison; and it appears to act as a powerful narcotic on many quadrupeds.

Bitu'men, a mineral substance, remarkable for its inflammability and its strong peculiar odour; generally, however, supposed to be of vegetable origin. The name, which was in use among the ancient Romans, is variously employed, sometimes to include a number of the substances called Mineral Resins (see RESINS), particularly the liquid mineral substances called Naphtha (q.v.) and Petroleum (q.v.) or Mineral Oil, and the solid ones called Mineral Pitch, Asphalt (q.v.), Mineral Caoutchouc, &c.; sometimes in a more restricted sense it is applied by mineralogists only to some of these, and by some mineralogists to the solid, by others to the liquid ones. All these substances are, however, closely allied to each other. Naphtha and petroleum consist essentially of carbon and hydrogen alone, 84 to 88 per cent. being carbon; the others contain also a little oxygen, which is particularly the case in asphalt, the degree of their

solidity appearing to depend upon the proportion of oxygen which they contain, which amounts in some specimens of asphalt to 10 per cent. Asphalt also contains a little nitrogen. It seldom occurs quite pure, but is usually mixed with sand or other inorganic ingredients. Not infrequently it is found impregnating sandstone, limestone, shales, clay-slates, &c., as at Val de Travers in Switzerland, at Limmer in Hanover, at Lobsann in Alsatia, &c. Such is the character of the so called fetid sandstones and limestones. From certain shales, mails, and slates, mineral oil is distilled in large quantities (see SHALE and MARL). Asphalt occurs plentifully on the shores and floating on the surface of the Dead Sea. It is met with in masses in many other places, as in Trinidad, in Venezuela (see BERMUDEZ, LAKE), at Los Angeles in California, Avlona (Valona) in Albania, &c. Now and again it occurs also, in small quantities, in mineral veins or lodes, where it is often mistaken for anthracite.

Closely related to asphalt are the pitch-like minerals called Grahamsite and Albetite, which occur in fissures in the Carboniferous system of North America. The latter mineral has likewise been met with in Scotland. Some authorities also include the well-known Boghead Coal (q.v.) under the general head of Bitumen.

One of the most interesting of the bituminous minerals is Elateite, known also as Mineral Caoutchouc or Elastic Bitumen. It is a very rare mineral, occurring in only a few localities—the Odin lead-mine in Derbyshire; a coal-mine at Montrelais, near Angers; a coal-mine near South Bury, Mass.; and at Newhaven, Conn. It is elastic and flexible like caoutchouc, and may be used, like it, for effacing pencil-marks. It is easily cut with a knife. Its colour is blackish, reddish, or yellowish-brown; and its specific gravity is sometimes a little less, and sometimes a little more than that of water. It has a strong bituminous odour, and burns with a sooty flame, its composition being CH_2 . Several substances occur in nature with a similar composition. Of these the best known is the mineral called Ozokerite. It is brownish, yellowish, or greenish in colour, streaked or spotted, and occurs in rudely fibrous masses, as at Slanik and Boryslaw in Galicia. It dissolves with difficulty in alcohol and ether. Various other natural products have been described as Ozokerite, to which they closely approach in chemical composition, and from which they seem to differ chiefly in their ready solubility in ether.

Bitzlius, ALBERT, better known under the *nom de guerre* of Jeremias Gotthelf, a popular Swiss author, bepraised by Ruskin, was born at Murten, in the canton of Freiburg, 4th October 1797. He studied theology at Bern, and became in 1832 pastor of Lutzelfluh, in Emmenthal, which office he retained till his death, 22d October 1854. A monument was reared to him in 1887. Bitzlius has assured himself lasting popularity by his masterly delineations of Swiss popular life. His stories are characterised by rare simplicity and truth, lightened by delicate humour and graceful fancy. The best and most popular of his stories are *Kathi, die Grossmutter* (1847); *Uli, der Knecht* (1841), and its continuation, *Uli, der Pächter* (1849); and *Erzählungen und Bilder aus dem Volksleben der Schweiz* (5 vols. 1852–55). In his later years he wrote several pamphlets against the German democrats, without, however, violating those popular sympathies and liberal convictions which pervade his writings, and which at an earlier period led him vehemently to oppose the Bernese aristocracy.

Editions of his works appeared in 1856–57 and in 1894–96, the latter with a *Life* by Vetter; and there are *Lives* by Brockhaus (1876) and Bartels (1902). See R.

Huch, *Jeremias Gotthelfs Weltanschauung* (1919) Ruskin edited a translation of *Urn the Farm Servant* (1888).

Bivalves form a class of shelled animals or molluscs in which the shell consists of two limy plates or valves, lying one on each side of the body. Mussel, oyster, cockle, and clam are very familiar examples. Compared with the other two great classes of Molluscs—the snails (Gasteropods) and the cuttle-fish (Cephalopods)—the bivalves are markedly quiet and passive. The great majority live a sessile life except during their youngest stages. With this inactivity certain characters are directly associated, of which the most marked are: (1) the undeveloped structure of the head; (2) the absence of head eyes; (3) the absence of biting or prehensile organs; (4) the marked development of large plate-like gills producing nutritive as well as respiratory currents; and (5) the presence of thick limy shells which exhibit most manifold variations within comparatively narrow limits.

History and Nomenclature.—Aristotle included bivalves among other shelled forms of very diverse structure in his great group of hard-skinned animals or Ostracodermata. Linnæus was content to refer them to an equally heterogeneous group of worms. Cuvier defined them more exactly as a subdivision of molluscs, and gave them the title of headless (Acephala), which they still frequently receive. To Owen is due the designation Lamellibranchiata, which refers to the plate-like character of their gills, and it is by this title that they are now generally known. The term Lipocephala is a yet more modern one referring to the undeveloped nature of the head, and the absence of the rasping tongue which is found in other molluscs (Glossophora). Bivalve shells are exhibited by other animals besides Lamellibranchs, and especially by the small class of lamp-shells or Brachiopods, but in the latter the structure of the animal is not in any sense that of a mollusc, and the position of the valves is ventral and dorsal, instead of lateral. The Brachiopods are therefore excluded from this article, in which the title bivalve is regarded as equivalent to Lamellibranch.

Structure.—(a) The body of the bivalve can usually be split along the middle line into similar halves; it is bilaterally symmetrical. It is usually compressed from side to side, the breadth or thickness being small in proportion to the other dimensions. (b) The ventral surface of the animal—i.e. where the valves gape, is usually produced into a very characteristic ploughshare-shaped

Fig. 1.—Longitudinal Section through a Fresh-water Mussel (after Marshall & Hurst, *Practical Zoology*): a, edge of mantle; b, foot, with position of ganglion indicated; c, gills; d, mouth; e, tentacles or palps; f, posterior adductor muscle; g, anterior adductor; h, head-ganglion; i, rectum; j, kidney; k, exhalant aperture; m, inhalant aperture.

muscular organ called the *foot*, which is used in boring and in locomotion, but tends to degenerate in the forms which are most inactive. From a gland frequently present in the posterior part of the foot, a viscid secretion is exuded in the form of threads (byssus) by which the attachment of

the bivalve is effected. (c) From the middle line of the back—i.e. from the hinge of the shell—a flap of skin falls down each side of the body, covering the animal entirely with a double cloak, and closely adhering to the valves of the shell. These two *mantle-skirts* meet one another by their free margins on the ventral side when the shell is shut, but are of course separated when the foot is protruded through the gaping aperture. They are in the closest connection with the shell, which they in fact produce. The shell is an organic growth, and consists of three layers. (a) soft and cuticular, (b) prismatic, and (c) mother-of-pearl. The growth takes place on the internal surface, and at the margin of the mantle. The concentric lines and the modifications of colour remain as indices of the rhythm of growth. In many forms the mantle is drawn out into a pair of lips forming a double tube or siphon. Through this the water, circulated by the gills, passes in and out. Many forms lie buried in the mud with the open ends of the siphons protruded. In Pecten, Lima, and others, the margin of the mantle bears numerous tentacle-like processes. (d) Between each mantle-skirt and the side of the body proper, lie the large and prominent *gills*, which are covered with ciliated cells, causing currents of water which not only purify the blood spread out upon the plates, but whirr minute food-particles to the inconspicuous mouth. They are indeed more nutritive than respiratory. (e) There is seldom any marked difference between the head and tail end of the animal; in the middle line in front lies the *mouth*, and the food-canal ends in a similar position behind. The canal itself lies mainly in the plane dividing the body into halves, but exhibits more or less looping in the region of the foot. A large gland (the so-called liver) is situated far forward near the stomach expansion. Still further forward, in the region of the pharynx, there often is a blind pocket containing a curious clear cylinder (the crystalline style), which some regard as the equivalent of the rasper found in other molluscs. Flat tentacles occur on each side of the mouth and look like small gills. They are richly supplied with blood-vessels and nerves. (f) The shell is opened by the action of a passive tendinous band (*ligament*) which lies at the dorsal meeting-place of the two valves, and acts like a piece of india-rubber squeezed into the hinge-line of a closed door: the shell is shut by one or two great muscles (*adductors*) which run across from valve to valve. There are also muscles, more or less powerful according to habit, for working the foot. The marks made by the insertion of the muscles on the shell are readily seen inside the empty valves. (g) The nervous system consists of three chief pairs of ganglia, the anterior cerebral pair being united by connectives to a pair in the foot (*pedal*), and to a posterior pair called

Fig. 2.—Vertical Section through a Fresh-water Mussel:

a, mantle; b, filaments of gills; c, ventricle of heart; d, auricle of heart; e, gut grown round by ventricle

parieto-splanchnic or *visceral*. From these three centres numerous nerves are given off to the body generally. An auditory sac (*otocyst*) is found in close association with the pedal ganglia, and a

patch of smelling or water-testing cells (*osphradium*) occurs at the base of the gills. Though eyes are never present on the reduced head, they sometimes occur in extraordinary abundance (to the number of many hundreds) along the margin of the mantle (e.g. *Pecten*, *Arca*). (h) The heart lies just below the hinge, and consists of a contractile median ventricle driving the blood to the body, and of two auricles symmetrically placed on each side, receiving purified blood from the gills. The ventricle usually grows round the gut, which thus appears to run right through the heart. The whole organ is inclosed in a special portion of the body-cavity known as the pericardium, and this is in indirect communication with the exterior by means of two (i) *kidney-tubes* (nephridia) which lie below the heart, and open externally on the sides of the body. (j) A pair of *reproductive organs* lie in the foot, and their ducts open laterally near the apertures of the kidneys, with which they are occasionally united. The sexes are generally separate, but may be united, and both those forms may occur within one genus (e.g. oyster).

Habit.—The majority of bivalves are marine forms, but not a few occur in fresh water. Between the rapidly swimming *Lima* and *Pecten*, and the entirely quiescent oyster, intermediate degrees of activity and passivity occur, but most decidedly incline towards the extreme illustrated by the oyster. In *Lima* and *Pecten* the valves are opened and shut with great rapidity, and swimming thus effected; in the razor-shell (*Solen*) water is forcibly squirted outwards from within the mantle-cavity, and the animal moves backwards; in the cockle (*Cardium*) the foot is vigorous enough to enable the mollusc to take small jumps; in many cases (*Teredo*, *Pholas*, *Lithodomus*, *Xylophaga*)

FIG. 3.—Several Forms of Bivalves :

A, *Avicula*; B, *Pectunculus*, with extended foot (a); C, *Venus*, with respiratory siphons (a, b) and extended foot (c); D, *Mya truncata*, showing respiratory siphons (a, b) and foot (c).

a permanent hole is bored in wood or stone; in the majority the foot is used for a slow creeping progression along the sand. From the nature of the nutrition, by the inwasting currents produced by the gills, it is evident that the food must consist of minute organisms. Algae, Diatoms, Infusorians, minute Crustacea, and the like form the principal diet.

Life-history.—In almost all cases the eggs are fertilised within the mantle-cavity. There they remain for some time sheltered in the gills, or even within special brood-chambers (*Cyclas*). In rare cases (*Galeomma*, *Kellia*) the larvæ issue as such from the genital apertures, but in the vast majority the eggs are developed as above noted within the mantle-cavity. The larvæ very generally enjoy a period of free-swimming life before

settling down, but in some cases even this seems to be suppressed. In the Fresh-water Mussel (q.v.) (*Anodonta*) the larvæ are not liberated by the mother except in the presence of certain fishes such as sticklebacks. On the gills of the latter the larvæ become temporarily parasitic, and undergo very considerable metamorphosis.

Classification.—The Lamellibranchiata are usually classified according to the development of the closing muscles of the shell.

ORDER I.—*Isomya*. Anterior and posterior adductors approximately equal:

Sub-order I.—*Integripallia*, where the line attaching the lower margin of the mantle to the valve is a continuous curve and not inflected—e.g. *Arca*, *Trigonia*, *Unio*, *Anodon*, *Lucina*, *Astarte*, *Tridacna*, *Chama*, *Cardium*, *Cyclas*, *Cypriina*.

Sub-order II.—*Sinupallia*, where the line attaching the lower margin of the mantle to the valve is not a continuous curve, but inflected to form a sinus—e.g. *Tapes*, *Venus*, *Tellina*, *Macra*, *Mya*, *Saxicava*, *Aspergillum*, *Pholas*, *Teredo*.

ORDER II.—*Heteromya*. Anterior adductor decidedly smaller than posterior—e.g. *Mytilus*, *Modiola*, *Lithodomus*, *Mulleria*.

ORDER III.—*Monomya*. No anterior adductor, and no siphons—e.g. *Cardiola*, *Avicula*, *Ostrea*, *Lima*, *Pecten*.

Distribution.—Bivalves are found all over the world, though only a few species like *Mytilus edulis* and *Saxicava arctica* can be described as cosmopolitan. The marine forms occur from the shore level down to great depths, and the same species is not unfrequently found at the most diverse depths. Historically, the bivalves appear in the Cambrian strata, though only to a slight extent. In the Lower Silurian they are still far from numerous, but Barrande enumerates 1100 species from the Upper Silurian of Bohemia alone. The *Heteromya* at first preponderate. From the Upper Silurian onwards, bivalves are exceedingly abundant, and the satisfactory preservation of their shells makes them of great value as index fossils in determining the age of given strata. Among Lamellibranchs occur some of the best instances of types persisting throughout long periods.

Pedigree.—The bivalves must be regarded as a group which has developed along a line entirely different from that of the other molluscs. From an ideal ancestral mollusc like that sketched by Ray Lankester, two lines of progress have been followed. On the one hand, the shell has remained single, the head has not been reduced, the buccal apparatus has developed, and the life has been relatively active. This path has been followed by *Gasteropods*, *Pteropods*, and *Cephalopods*. On the other hand, along the other line, the mantle has become bilobed, the shell double, the gills large, plate-like, and nutritive, the head much reduced, and the life relatively passive. This path has been followed by the Lamellibranchs.

Economic Importance.—Many bivalves (oyster, mussel, cockle, clam, &c.) are used for food. Others are largely utilised as bait in sea-fishing. Pearls and mother-of-pearl are obtained from *Meleagrina* and other forms. The valves of *Placuna* are sometimes used for window-panes. *Venus mercenaria* and other types have been used by savage tribes for coinage. Larger shells are occasionally calcined for lime. The boring bivalves have an important destructive influence on piers and ship timber, but ensheathing in metal renders their attack less effectual. See CONCHOLOGY, MOLLUSCS, OYSTER, &c.; Huxley's *Anatomy of Invertebrated Animals* (1877); Ray Lankester's *Natural History* (1906).

Biv'ouac (through Fr. from Ger. *beiwache*: *bei*, 'near,' and *wachen*, 'to watch') is the encampment of soldiers in the open air, without tents, where

every one remains dressed in his place, and with his weapons by him. It used to be held necessary for opposing armies thus to pass the night before a battle. The French revolutionary armies first introduced the practice of dispensing with tents throughout the campaign, thus greatly lessening their baggage-trains and increasing the celerity of their movements. A European army carries tents only for reserves and hospitals. In populous country full use is made of buildings for all troops not in or very near the firing-line (see BILLETING, CAMP). Troops not thus accommodated bivouac. Each battalion, or other unit, has its allotted space, in the centre of which the arms are piled in quarter column. Round the piles of arms each company has its sleeping-ground marked out. A bivouac would, if possible, be placed under the shelter of trees, or so as to be protected from wind by hedges. Improvised screens of straw, heather, &c. would be used, and large fires lighted. But the health of troops always suffers if bivouacked constantly in bad weather. In India and other hot countries it is found necessary to carry tents still, and the bivouac is never resorted to if it can be avoided.

Bixa. See ANNATTO.

Bizerta, or BENZERTA, a fortified seaport of Tunis, at the head of a bay of the Mediterranean, and at the mouth of a lagoon, united to the bay by a narrow channel. It is the most northerly town in Africa, being 38 miles NW. of Tunis. Its port, formerly one of the best in the Mediterranean, has again been deepened, provided with a dry-dock (1905), and made a great French naval station. The tunny, mullet, and coral fisheries are very productive. Pop. about 20,000.—The ancient *Hippo Diarrhytus* or *Zaritus*, Bizerta was founded by the Tyrians, was fortified by Agathocles in 307 B.C., and under the Romans was a free city. Since 1881 it has been held by the French.

Bizet, GEORGES, a French composer, was born 25th October 1833 at Paris, and studied at the Conservatoire under Halévy, and in Italy. His earlier operas, *Les Pêcheurs de Perles* (1863), *La Jolie Fille de Perth* (1867), showed Wagnerian sympathies and had little success; but his music to Daudet's *L'Arlesienne* was popular, and his comic opera *Carmen* (1875) was not more remarkable for its originality and dramatic effectiveness than for its success. He had just begun to taste the sweets of popularity when on 3d June 1875 he died. See *Lives* by Pigot (1889) and Bellaigue (1891).

Bjala, a Polish town, 38 miles SE. of Siedlce; pop. 13,000.

Björneborg, or PORI, a port of Finland, on the Kokemäen River, 60 miles NNW. of Abo, exporting timber, tar, and fish; pop. 20,000.

Björnson, BJÖRNSTJERNE, a celebrated Norwegian writer, was born 8th December 1832, at Kvikne, in Osterdalen, where his father was pastor. After studying at the university of Christiania from 1852, and then for a year at Copenhagen, he returned to Norway in 1857, and published his beautiful tale *Synnove Solbakken*, which at once attracted universal attention, and is still regarded as having marked an epoch in the recent literature of Norway. Immediately afterwards he was appointed manager of the Bergen Theatre by its proprietor Ole Bull, and in 1858 he published the tale *Arne* and the drama *Halte-Hulda*. In 1859 he left Bergen to be editor of the newspaper *Aftenbladet* at Christiania, but his stay there was cut short by the violent controversies in which he soon became involved; and in consequence he withdrew the next year to Copenhagen, where he collected a number of his shorter tales, and

brought them out, together with the drama *Mellem Slagene*, under the title of *Smaastrykker*. From 1860 to 1862 he lived in Rome, where he wrote several lyrical poems, the drama *Kong Sverre* (1861), and the trilogy *Sigurd Stenbe* (1862); and on his return to Norway in 1863 the Storting awarded him a yearly pension. In the next two years he produced two plays, *Marie Stuart in Skotland* and *De Nygifte*, for the theatre at Christiania, of which he was director from 1865 to 1867, at the same time editing a paper. In 1872-76 he again lived abroad. He was a powerful political orator, and took an active part in the movement which led to the victory of parliamentary government in Norway. Though he lived in Paris in 1883-88, he was still a leader of the 'Peasants' Party,' and at home and abroad he was a somewhat narrowly patriotic anti-Swede as well as democrat; but he protested against the artificial introduction of a patriotic Norwegian language as distinct from the customary Dano-Norwegian. Many of his plays are polemical or satirical—amongst these *The King*, *Leonarda*, and *The New System*; *A Gauntlet* (1883) was a skilful problem play; *A Bankruptcy* (1875) pleased better on the stage; *Beyond Human Power*, in two parts, is mystical, symbolical, religious. Of his many novels the most famous were *Flags are Flying* (1884; trans. as *The Heritage of the Kurts*) and *The Paths of God* (1889; trans. as *In God's Way*). *Mother's Hands* and *Absalom's Hair* were striking short stories. *Geography and Love*, *Paul Lange*, and *Laboremus* were later plays. He died 26th April 1910.

Most of the plays and novels have been translated, some of them two or three times over; *Synnove Solbakken* was translated by Mary Howitt as early as 1854. See Brandes, *Björnson and Ibsen*, and his *Main Currents* (1905); the essay by Gosse in the series of translations edited by him (1892-97); Tissot, *Le Drame Norvégien* (1893).

Björnstjerna, MAGNUS, COUNT, a Swedish liberal statesman, born in 1779, in 1813 fought at Leipzig, and in 1814 he concluded the treaty that united Norway with Sweden. In 1828-46 he was ambassador to Britain. He died in 1847.

Blaas, KARL VON (1815-94), painter, born at Nauders in Tyrol, studied at Innsbruck and in Italy, was professor at Vienna and Venice. He painted many frescoes besides portraits and other works, and wrote an autobiography.

Blacader, ROBERT, bishop of Aberdeen and of Glasgow, and first archbishop (1492) of Glasgow, is said to have died in 1508 on a pilgrimage to Jerusalem.

Black may be considered as the negation of colour, resulting from the absorption of the rays of light by certain substances. Painters produce it approximately by an unequal combination of red, blue, and yellow (see COLOUR; also DYEING). In medieval art, black was symbolical of evil, error, and woe; and is still a usual funereal colour (see FUNERAL RITES). For its use in Heraldry, see HERALDRY, HATCHMENT.

BLACK PIGMENTS, used in painting, are derived principally from animal and vegetable substances. The most important are: *Lamp-black*.—The finer kinds are prepared from the soot of burnt resin or resinous woods. The coarser varieties are made from the soot of an oil obtained from gas-tar and other cheap bodies. This black is much used by painters, and it is also employed for making printing ink.—*Blue-black* consists of levigated charcoal from vine twigs. It is also a very serviceable black for artistic work.—*Bone-black* and *Ivory-black*, as their names imply, are simply animal charcoal, and consequently possess the power of absorbing colour from animal and vegetable solutions. Therefore they cannot be safely mixed with other organic

colours in water-colour painting. The above pigments are, of course, prepared either with oil or gum, according as they are to be used in oil or water-colour work.—*Indian Ink* (see *INK*) is a black prepared from a vegetable carbon, and so far resembles lamp-black, but it is not very suitable for mixing with other colours. For black dyes, see *DYEING*.

Black, ADAM, publisher, was born in Edinburgh, 20th February 1784, and, trained as a bookseller there and for two years in London, he with a nephew established the Edinburgh business of Adam and Charles Black. The two enterprises which, above all else, gave position, fortune, and success to the firm, were the purchase of the copyright of the *Encyclopædia Britannica* in 1827 after Constable's failure; and that of Scott's novels from Cadell's representatives in 1851 for £27,000. A seventh and eighth edition of the *Britannica* was issued during Black's business connection with the firm, while Scott's novels had a large and steady sale. Black was long a prominent and useful citizen of Edinburgh; was twice Lord Provost; and was Liberal M.P. for Edinburgh (1856–65). He died 24th January 1874. A statue was erected in Edinburgh in recognition of his services in 1877. See *Memoirs* by Nicolson (1885).

Black, JOHN, journalist, was born near Duns, Berwickshire, in 1783. Left an orphan ere he had reached his twelfth year, Black, after filling posts in the offices of a Duns writer and an Edinburgh accountant, in 1810 went up to London, and was engaged as a parliamentary reporter for the *Morning Chronicle*, of which from 1817 he assumed the editorship. Under him the paper was celebrated for its independence and fearless advocacy of progress—a fearlessness which led to his duel with Roebuck in 1835. Charles Dickens was one of his reporters, and contributors, and James Mill helped him with almost daily advice. John Stuart Mill has described him as 'the first journalist who carried criticism and the spirit of reform into the details of English institutions.' He retired from the editorship in 1843; an annuity of £150 a year was bought for him by his friends; and, until his death on 15th June 1855, he lived in a pleasant cottage at Snodland, near Maidstone. Black was author of a *Life of Tasso* (1810), and the translator of works from the German, French, and Italian.

Black, JOSEPH, an eminent chemist, was born in 1728, at Bordeaux, where his father was engaged in the wine-trade. Both his parents were of Scotch descent, but natives of Belfast, to which city their son was sent for his education in 1740. In 1746 he entered the university of Glasgow, and studied chemistry under Dr Cullen. In 1751 he went to Edinburgh to complete his medical course, and in 1754 took his degree. In his famous graduation thesis (1756) he showed that the causticity of lime and the alkalies is due to the absence of the carbonic acid present in limestone and in what are now called the carbonates of the alkalies. To this he gave the name 'fixed air,' which gave way before that of 'carbonic acid,' first used by Lavoisier in 1784. The book was a distinct contribution to chemical science, and by Brougham and Robison is placed second only to Newton's *Optics* as a model for scientific investigation. Black pointed out the path afterwards followed by Cavendish, Priestley, and Lavoisier. On the removal of Cullen in 1756 to Edinburgh, Black succeeded him as professor of Anatomy and Chemistry in Glasgow, but soon after exchanged duties with the professor of the Institutes of Medicine, and lectured on the subject for ten years, practising the while as a busy physician, yet finding time for original investigation.

Between 1756 and 1761 he evolved that theory of 'latent heat' on which his scientific fame chiefly rests, and which formed the immediate preliminary to the next great stride in discovery by his pupil and assistant, James Watt. In 1766 he succeeded Cullen in the chair of Medicine and Chemistry in Edinburgh, and henceforward he devoted himself chiefly to the elaboration of his lectures, in which he aimed at the utmost degree of perspicuity, and with perfect success. His class became one of the most popular in the university; it occasioned, however, some disappointment that one so capable of enlarging its territory made no further contributions to chemistry. Though of an extremely delicate constitution, he prolonged his life, by care and temperance, till 6th December 1799. His lectures were edited by Professor Robison (1803). See his *Life and Letters* by Sir William Ramsay (1918).

Black, WILLIAM, novelist, was born in 1841 in Glasgow, where he received his education, and studied art at a government school with the view of becoming a landscape-painter. Instead, however, he adopted journalism, having written for the *Glasgow Weekly Citizen* prior to his removal to London in 1864. During the Prusso-Austrian war of 1866 he was employed as special war correspondent on the staff of the *Morning Star*; and in a novel, *Love or Marriage* (1868), he utilised some of his experiences. In *Silk Attire* (1869) and *Kilmeny* (1870) proved more successful than the previous work; but it was *A Daughter of Heth* (1871) that established his reputation with the novel-reading public. *The Strange Adventures of a Phaeton* (1872) is founded on an actual driving excursion between London and Edinburgh. *A Princess of Thule* (1873) is the best perhaps of all his many romances, with its vivid transcripts of Hebridean scenery, its quaint Gaelic-English, above all, its exquisite heroine. Among its successors are: *Three Feathers* (1875); *Madcap Violet* (1876); *Green Pastures and Piccadilly* (1877); *Macleod of Dare* (1878); *White Wings* (1880); *Sunrise, a Story of these Times* (1880); *Shandon Bells* (1882); *Yolande* (1883); *Judith Shakespeare* (1884), with Shakespeare himself for one of the characters; *White Heather* (1886); *Sabina Zembra* (1887); *In Far Lochaber* and *The Strange Adventures of a House Boat* (1888); *The Penance of John Logan* (1889); *New Prince Fortunatus* (1890); *Stand Fast, Craig Royston* (1890); *Wolfenberg* (1892); *Handsome Humes* (1893); *Highland Cousins* (1894); *Briseis* (1896); *Wild Eelin* (1898). Assistant-editor for five years of the *Daily News*, Mr Black in 1874 abandoned journalism. He died 10th December 1898.

Black Acts are a collection of the acts of the Scottish parliament from 1424 to 1594, printed in Black-letter (q.v.); the hated anti-Presbyterian acts of the Scottish parliament of 1584; also the English act of 1723 concerning poachers who disguised their faces in black for the purpose of committing offences.

Black Art. See *MAGIC*.

Black Assize, the popular name commemorative of an extraordinary and fatal pestilence which broke out at Oxford at the close of the assizes, July 6, 1577. It was popularly interpreted as a divine judgment on the cruelty of a sentence passed by the court. From the 6th of July to the 12th of August, 300 persons in Oxford and the neighbourhood are said to have died of this terrible malady, among whom were the chief officials who sat on the assize, most of the jury, and many members of the university. Women, poor people, physicians, visitors, and children are said to have escaped the infection. A similar event is recorded as having taken place at Cambridge at the Lent Assizes in 1521.

Black-band Ironstone is an ore of iron which has been extensively worked in Scotland and elsewhere. It occurs in the Carboniferous system in regular bands or layers, and is generally associated with coal and limestone. It is mainly a carbonate of iron with much coaly matter. The black-band ironstone is easily reduced. It does not, however, yield a first-class iron when smelted by itself, and is therefore generally mixed with a small quantity of hematite, which communicates strength and hardness to the iron obtained.

Black Beer. See SPRUCE BEER.

Black Beetle, at once a popular and a scientific term—popular when applied widely to all sorts of forms, from Blaps (q.v.) to the Cockroach (q.v.), which is not a beetle at all; scientific when restricted to a great family of beetles known as Melanosomata in the Heteromeres sub-order of Coleoptera. The possible extent of the term will be evident when it is noted that even when restricted to these Melanosomata, it may be applied to 600 genera and about 4500 species. These Melanosomata (Gr., 'black-bodied') have short strong upper jaws, the eyes to the sides, the feelers usually with 11 joints, the uppermost joints of the legs almost always separate (the anterior pair spherical and sunk in sockets, the posterior lying transversely), the wing-covers often fused, and in these cases without wings, the abdomen with five free joints. They love dark damp places, though a few less dismally coloured, for the prevalent black is sometimes relieved, get out into the open. They mostly have a bad smell. The larvæ are very long and narrow. The familiar Blaps, the Bolitophagus of fungus, the very abundant Hypophloeus, living under the bark of old trees, the Tenebrio, with its larva the *Meal-worm*, so much used in feeding birds, are some of the commonest genera of Melanosomata or black beetles.

Blackberry. See BRAMBLE.

Blackbird, or MERLE (*Turdus merula* or *Merula vulgaris*), a well-known species of Thrush (q.v.), common in all parts of Britain, and throughout Europe generally; found also in the north of Africa, and in the Azores. In Asia, it gives place to a closely allied species, *Turdus pacillopterus*. In size, the blackbird is intermediate between the

Blackbird.

missel-thrush and the song-thrush or mavis. The plumage of the adult male is wholly of a deep black colour, the bill and orbits of the eyes yellow; the female and the young are dark brown above, paler on the throat, and rusty brown on the breast, with brown bill, yellow, however, in spring-time. Very old blackbirds have the feathers on the back of the neck tipped with fine hairs. White, cream-coloured, and other variations occasionally occur. The blackbird frequents hedges, thickets, and woods; is shy, restless, and vigilant, keeping much under cover of

evergreens or shrubs; and when disturbed, takes wing with a vociferous chattering of alarm, seeking refuge in some neighbouring thicket. Its food consists of worms, snails, insects, berries, seeds, &c. Its fondness for fruit makes it often annoying to the gardener; but probably it would in general be better to protect cherries and pears by nets than to shoot the bird, which is of great use as a destroyer of insect larvæ. Like some of the other thrushes, it also devours (especially in winter) great numbers of small snails, dexterously breaking the shell against a stone. When searching for food, it jumps about with characteristic alacrity; when disturbed, it flies off with a somewhat magpie-like chuckle; its familiar flight along the hedges is 'wavering and fitful,' and in the breeding-season the female especially moves by a succession of starts. It is not usually a gregarious bird, although great flocks sometimes appear upon British coasts in winter, arriving from more northern lands; and probably at that time the blackbirds with us in summer go south. It pairs very early in spring; the male and female are indeed very often seen together during winter; it builds its nest early, and generally has two broods in the year. The nest is usually placed in some thick bush; it is of ruder workmanship than that of the song-thrush, which, however, it resembles, and is usually formed of strong stems of grass, with a finer lining of dry grass inside, and a massive plastering of clay outside. The inside and outside of the nest are kept very clean, and a male has been seen to remove the dropping of a young bird from the vicinity of the nest. The male aids in the work of feeding the young. The eggs are four or five in number, of a pale blue colour, generally speckled with brown. A female blackbird and a male thrush have been known to pair. The voice of the blackbird is very powerful, and its song more mellow than that of the thrush, but with 'much less variety, compass, or execution.' The blackbird is often kept as a cage-bird, and would be much more frequently so, but for the too great loudness of its song; it is readily trained, exhibits considerable powers of imitation, and has even been taught to articulate.—The Ring Ouzel (q.v.), sometimes called the Ring Blackbird, is a nearly related species (*T. torquatus*).—The Crow, the Redwing, and other blackbirds of America are entirely different.—The Savanna Blackbird of the West Indies is also of a different family. See CROTOPHAGA.

Black Book, an interesting collection of English Admiralty Law in the 14th century, first edited by Sir Travers Twiss (4 vols. 1871-76). It indicates the pretensions of the civil law as regards trial without jury, torture, &c., which afterwards led to legislation in vindication of the position of the Common Law courts.—BLACK BOOK is also a usual term for the reports presented to parliament in 1536, on which the legislation for the dissolution of the monasteries and the secularising of their revenues proceeded. These reports probably never existed as a book (fabled to have been burnt in Queen Mary's reign); such of them as remain are to a large extent extravagant and malicious accusations without any evidence (see *Letters and Papers of the Reign of Henry VIII.*, edited by James Gairdner, vol. x. 1888; Cardinal Gasquet, *Henry VIII. and the English Monasteries* (2 vols. 1888-89).—A list of habitual criminals, first published in 1877, has been also so called.

Black-boy. See GRASS-TREE.

Black-bryony. See BRYONY.

Black-buck, the common Indian antelope (*Antelope cervicapra*). See ANTELOPES.

Black-bully, or BALLY-TREE WOOD See CHEWING GUM, SAPODILLA PLUM; and for another Black-bully, see BULLET-TREE

Blackburn, a town of Lancashire, 21 miles NNW. of Manchester, and 9 E. of Preston. It stands on a stream from which it appears to derive its name, a branch of the Ribble. The surrounding district, formerly known as *Blackburnshire*, or *Blagbornshire*, was long very wild and dreary, but now is densely populous. Coal was formerly plentiful, and lime still abounds in it. Blackburn had acquired some importance as a market-town in the 16th century. Its manufacturing prosperity can be traced back at least to the middle of the 17th century, when it was noted for the production of a kind of linsey-woolsey known by the name of *Blackburn Checks*, afterwards superseded by the *Blackburn Grays*, so called from their being printed unbleached. In the course of the 18th century the cotton manufacture became the chief industry of the town, which is now a great centre of manufacture, the cotton-factories being numerous and large, many of them employing from 1000 to 2000 operatives. The iron trade is important, and machine making employs many hands. Great improvements in machinery for the cotton manufacture have been made in Blackburn, among which the first place in importance as well as in date must be assigned to the invention of the spinning-jenny by James Hargreaves (q.v.), a native of the town, in 1767. His invention, however, was regarded with so much dislike that he was compelled to remove from the town, and it was not till the 19th century that it came into general use. The growing importance of Blackburn is seen in the increase of its population from 36,629 in 1831 to 63,126 in 1861, 104,014 in 1881, and 133,052 in the extended area of 1911; the 1921 census (126,630) was taken during a holiday season. The chief public buildings are the town hall (1856), an Italian edifice; the Gothic exchange (1865); the infirmary (1862); and St Mary's Church, of very ancient foundation, but almost entirely rebuilt (1826-57). The National Assembly in 1923 decided on establishing a bishopric. There is a corporation park of 50 acres, part of which is 700 feet above sea-level, and commands a wide view; also a Queen's Park of 35 acres (1887). The grammar-school was established by Queen Elizabeth in 1567. There is a technical school. Blackburn has returned two members since 1832; it received its municipal charter in 1851, and became a county borough in 1888.

Blackburne, FRANCIS, Lord Chancellor of Ireland, was born at Great Footstown, County Meath, 11th November 1782, and in 1798 entered Trinity College, Dublin. Called to the English bar in 1805, to the Irish in 1822, he was appointed Attorney-general for Ireland in 1830 and again in 1841, Master of the Rolls in 1842, Chief-justice of the Queen's Bench in 1846, and Lord Chancellor of Ireland in 1852 and 1866. He thus served under both Whig and Tory governments, and was brought into close connection with the leading politicians on either side; whilst at different times he had the duties imposed on him of prosecuting O'Connell, and judging Smith O'Brien. In 1867 he declined an offer of a baronetcy, and for some years he was Vice-chancellor of Dublin University. He died 17th September 1867. See the Life by his son (1874).

Black Canons. See AUGUSTINIANS.

Black Cap, the cap worn by English judges as a part of full dress, and so put on by them when a prisoner is condemned to death.

Blackcap, BLACKCAP WARBLER, or BLACKCAP FAUVETTE (*Sylvia atricapilla*), a bird of the great family of the Sylviadæ, or Warblers. It is regarded as the sweetest song-bird in Britain, or

indeed in Europe, except the nightingale, to which it is said to be even superior in 'its shake or trilling note.' Very often, however, the strain is desultory, and of short continuance; but it is loud, rich in tone, and has a 'great variety of sweet and gentle modulations.' The song is especially joyous during and after rain. White says, in his *Natural History of Selborne*, that while the Blackcap warbles, its throat is wonderfully distended. It is a rather smaller bird than the nightingale; the female is larger than the male. The general colour is gray,

Blackcap (*Sylvia atricapilla*).

with an olive tinge above, and becoming white below. The upper part of the head in the male is jet-black; in the female, of a rusty-brown colour. The feathers of the head, both in the male and female, are somewhat erected, giving the bird a hooded appearance, on account of which it is called, in Germany, 'the monk.' In Britain, the Blackcap is only a bird of passage, arriving early in spring, and returing in September. It is most frequent in the southern counties of England, but is found even in Scotland; on the Continent, it extends its migrations as far north as Lapland. In the south of Europe, it is found both in summer and winter, and especially frequents bushy places. Its beautiful song, sometimes spoilt by successful mimicking, and its lively affectionate habits, make it a favourite captive. See WARBLER.

Blackcap Titmouse, or CHICKADEE, a North American bird. The Marsh Titmouse, a British bird, is sometimes called Blackcap, or Blackcap Titmouse. See CHICKADEE and TITMOUSE.

Black Chalk. See CHALK, BLACK.

Blackcock, HEATH-FOWL, or BLACK GROUSE (*Tetrao tetrix*), a species of Grouse (q.v.), abundant in Britain wherever there are moors of considerable extent, and more particularly where there are bogs and morasses with rank herbage, or, adjacent to the moors, natural woods or young plantations of pine and fir. Comparatively rare in the south of England, the blackcock becomes more common towards the north, and is very plentiful in the mountainous parts of Scotland. It is found in some of the Hebrides, but not in the Orkney or Shetland Isles. The only other British species, the Capercailzie (q.v.) or Wood-grouse, became some time ago virtually extinct in Britain, but the noble bird has now been reinstated. On the continent of Europe it occurs both in mountainous and marshy countries, as on the Alps and in Holland; it is found as far south as the Apennines, and as far north as the forests of Lapland; it abounds in most parts of Scandinavia, where it is carefully protected, the males only being killed, but these in great numbers for the London market; it is diffused over almost all parts of Russia, and is found in Siberia. Its range is restricted to the

Eurasian continent. The male is much larger than the female, sometimes weighing as much as 4 lb., while the female weighs only about 2 lb. They also differ very much in plumage. The male is of a shining bluish black colour, with a conspicuous white bar on the wings below the ends of the great wing-coverts, and a mixture of black and white on the legs; there is a piece of bare scarlet skin above the eye; the outer feathers on either side of the tail are elongated and curve outwards, giving it a very peculiar appearance. The female, called the *Gray Hen*, is of a rusty-brown colour, darkest on the

Blackcock (Male and Female).

upper parts, everywhere barred and mottled with a darker colour; the tail is straight and only slightly forked at the end. The young males resemble the females in plumage. The shank in this species is feathered, but not the toes. The flight, though heavy, is strong and rapid, and the birds can also run with much agility. It is a gregarious bird, but in winter the sexes generally keep in separate flocks. In spring the males resort to elevated and open spots, where they crow, and also make a sound which has been likened to the whetting of a scythe, thus inviting the females to repair to them; they strut and trail their wings like turkey-cocks, and fierce contests often take place among them. They are polygamous, and pay no attention to the females during incubation, nor do they take any part in rearing the young. The nest is of the simplest construction, a few straws or the like, placed together among tall heath, or under the shelter of a low thick bush. The eggs, six to eight in number, are yellowish-white, speckled with orange-brown, and about 2 inches long. The usual food consists of the seeds of rushes and other plants, berries, insects, worms, the tender shoots of heath, leaves, &c. But the blackcock sometimes visits cornfields and stubbles to feed on corn, is frequently to be found in turnip-fields near plantations in hilly districts, and, at least in winter, eats the young shoots of pines, firs, birches, and alders. It is highly esteemed for the table. The shooting season is from 20th August to 10th December.

Hybrids between different species of grouse, and even between grouse and pheasant, are said to exist, but not much reliable information is available. Thus it is probable that the bird called *Tetrao hybridus* or *medius*, sometimes found in the Scandinavian peninsula and other parts of Europe, is a hybrid between the Black Grouse and the Capercaillie, *Tetrao urogallus* (q.v.). The Ptarmigan (q.v.) or Brown Grouse are nearly allied.

Black Death is one of the names given to a fearful epidemic which desolated the world from China to Ireland in the 14th century. It raged in England and the rest of Europe in 1348-49, again in 1361-62, and in 1369; and at the time was usually called in England the 'Pestilence' or the 'Great Pestilence.' It is now believed to have been a specially severe visitation of the oriental plague (see **PLAGUE**), with some special symptoms, mainly boils or buboes on the thighs and arms, and putrid inflammation of the lungs, with vomiting of blood. Its black spots (whence the name) and tumours were the seals of a doom that medicine had no power to avert. In most cases the victims died in two or three days, and sometimes the very day they were stricken.

The pestilence seems to have originated in China, and is said to have been preceded, if not, as was believed, in some measure caused, by strange convulsions of nature—earthquakes, droughts, famines, floods, and swarms of locusts, while its westward course was accompanied by dense and awful fogs, and an apparent inversion of the order of the seasons. There had been a visitation of the ordinary plague in 1342; but it was in 1348 that Europe was terrified by the approach of a wholly unparalleled scourge. In China 13,000,000 were reported to have perished, and 24,000,000 elsewhere in the East. By the northern coast of the Black Sea and Constantinople, the contagion reached the seaports of Italy and Southern France, whence Germany and England were infected. The first English victims succumbed in Dorsetshire in August 1348; but it was not till winter that it reached London by way of Gloucester and Oxford. The havoc was almost incredible, but is well attested. Towns were stripped of their inhabitants; religious houses lost nine-tenths of the inmates. In London 100,000 died, 50,000 being buried in a plot of ground now covered by Smithfield; and Norwich mourned 60,000 deaths. Careful investigators have come to the conclusion that the victims of this one visitation must have comprised one third if not one-half of the total population of England, which is estimated to have then been from 3,000,000 to 5,000,000 in all. For a time Scotland enjoyed immunity, and spoke of the 'foul death of the English;' but ere long, like Ireland, it was also severely visited.

The mortality caused by the plague was only one startling consequence. Religious excitement led to extravagances of fanaticism, especially in Germany, to that of the Flagellants (q.v.); all natural bonds of human society were loosened, so that friend deserted friend and mothers fled from their stricken children, and the demoralisation showed itself in many cases in reckless debauchery. Elsewhere perverted Christian zeal led to frightful persecutions of the Jews, as at Mayence, where 12,000 Hebrews were believed to have been massacred.

But it is only in modern times that the extent of the economic and social consequences of this plague has been fully understood; the black death forms a great economic turning-point in English history. The dearth of labourers caused wages in England to be nearly doubled; law after law was passed to prevent the inevitable rise in the payment of labour; and the ill-feeling thus engendered between landholder and tiller of the soil led to numerous social changes and the rebellion of Wat Tyler. Old methods of culture disappeared; farms on lease largely took the place of great estates managed by bailiffs.

The great pestilence is referred to by Chaucer and Langland; Boccaccio's *Decameron* gives a singularly vivid view of its ravages in Florence;

but see the article **PLAGUE**; Hecker's *Epidemics in the Middle Ages* (1843); Creighton's *History of Epidemics in Britain* (1892); Jessopp's *Coming of the Plagues* (1888); works by Thorold Rogers, Cunningham, Denton (for the economic aspects), and (for subject as a whole) Cardinal Gasquet, *The Great Pestilence* (1894).

Black Draught. See **MAGNESIUM, SENN.**

Black Earth (*Tchernozem* of Russian geologists) is the name given to a deposit which covers vast areas in South Russia, extending over the steppes and low-lying plateaus that border on the Black Sea, and the depressed area to the north of the Caspian, with a breadth from north to south of from 200 or 300 to nearly 700 miles. It closely resembles the Löss (q.v.) of Central Europe in texture and structure, for it is fine grained, and is usually devoid of stratification. It varies in colour, however, from dark brown to black, and in thickness from a foot or two up to 6 or 7 yards, occasionally reaching, it is said, even to 60 feet. It is composed chiefly of siliceous sand (about 70 per cent.), alumina and other ingredients (23 per cent.), and organic matter (about 7 per cent.). But the composition is variable, the organic matter sometimes exceeding 10 per cent. It bears the same relation to the glacial accumulations of Russia that the Löss of the Rhine, the Danube, &c. does to those of central Europe, and is probably partly of aqueous, partly of wind-blown origin. According to some geologists, indeed, it is wholly due to the action of constant fohn winds, descending from the great ice-sheet which formerly covered much of northern Europe. As that ice-sheet retreated its morainic and fluvio-glacial accumulations were exposed, and, becoming desiccated, yielded much fine dust, which continued to be swept southward until, with the gradual disappearance of the ice-sheet, the fohn winds ceased.

Black Eye. See **BRUISE.**

Blackfeet Indians, a tribe of friendly Algonkians, generally Roman Catholic, now living in Montana and British America.

Black-fish (*Centrolophus pompilus*), a bony fish of the family Stromateidae, in the division with spinous rays (*Acanthopterygii*). It is nearly allied to the beautiful *Coryphæna* (q.v.), so frequently called dolphins. Though found in the Mediterranean, on the western coasts of Europe, and occasionally on the southern coasts of Britain, it is everywhere rare, perhaps because it is an inhabitant chiefly of deep waters. It is known to attain a length of more than 30 inches, and a weight of 14 lb. The general form is not unlike that of a perch; there is a single elongated dorsal fin with short rays; the dentition is very feeble; the body is covered with minute scales; the skin is tough and can be stripped off like that of an eel; there is no air-bladder. The colour is black, that of the fins intensely so. It is remarkable for great strength and velocity, and as an article of food is described as delicious. Another British species (*C. britannicus*) is also recorded, and the genus *Stromateus* is closely allied. The name is locally given to various species of fish, and even to small whales and dolphins.

Black Flux is prepared by heating in a covered crucible ordinary or crude cream of tartar, the bitartrate of potash, $\text{KHC}_4\text{H}_4\text{O}_6$, when the tartaric acid, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$, is decomposed, and charred, forming carbonic acid, CO_2 , which remains in combination with the potash as carbonate of potash, K_2CO_3 , accompanied by much free carbon. This very intimate mixture of carbonate of potash and carbon, otherwise called black flux, is a fine black powder of great service in the fluxing of metallic ores, as of Lead (q.v.), and the separa-

tion of the metal therefrom. In the preparation of black flux it is usual to add to the cream of tartar half its weight of nitre, while *white flux* is produced when twice its weight of nitre is used. The black flux is likewise employed as the raw material from which, on the application of heat in iron vessels, the metal potassium can be obtained.

Black Forest (Ger. *Schwarzwald*), a wooded mountain-chain in Baden and Württemberg, running parallel with the course of the Rhine after its great bend near Basel, and often only a few miles distant from it. The Rhine also bounds it on the south, and the level country between the Enz and the confluence of the Neckar with the Rhine borders it on the north. The chief rivers rising in the Black Forest are the Danube, Neckar, Murg, Kinzig, Elz, Enz, and Wiessen. Of these, the valley of the Kinzig divides the southern and loftier portion from the northern district. The chain attains its greatest elevation in the bare and round-topped Feldberg (4903 feet high), above celebrated Hollenthal, a narrow valley known in connection with Moreau's retreat in 1796. The great mass called the Kaiserstuhl (Emperor's Chair), situated near Breisach, is quite isolated. As to the geological character of the mountains, primitive granite and gneiss form their core, porphyry occurs on their sides, and sandstone in the north and east. Silver, copper, cobalt, lead, and iron are found in greater or less quantity in the principal chain, which is luxuriantly wooded, its name Schwarzwald being derived from the dark-tinted foliage and immense number of its fir-trees. The district is also rich in mineral waters—e.g. the baths of Baden-Baden (q.v.) and Wildbad (q.v.). On the Rhine side the descent is precipitous, but towards the Danube and the Neckar it is gradual. Among its numerous valleys, the Murgthal is the most famous for its natural beauties; but, indeed, the whole of the country is here rich in picturesque scenery, gemmed with cascades and deep mountain-lakes, around which cluster the legends of many centuries. The climate is healthy, but severe, although the western slopes are studded with vineyards. Summer rye, oats, and potatoes are cultivated in some parts, but with difficulty, the rearing of cattle being attended with much greater success. This, and the manufacture of articles of wood, forms the chief industry of the inhabitants. The making of wooden clocks and other kinds of timepieces employs thousands of persons; and great numbers of articles of this kind, including musical boxes, are exported to all parts of the world. A railway starting from Pforzheim makes the complete circuit of the mountains, which are now crossed by a line from Offenburg to Singen, and by numerous shorter lines. The Black Forest railways have been difficult engineering enterprises. The line between Freiburg and Neustadt rises 2000 feet in 22 miles, and at some parts has rails on the rack system. See Seguin's *Black Forest, its People and Legends* (2d ed. 1886).

Black Friars. See **DOMINICANS.** The old Dominican monastery in London, dating from 1276, stood near the north end of Blackfriars Bridge.

Black Friday is a name given to the 11th May 1866, from a commercial panic then at its height, caused by the stoppage of Overend, Gurney, & Co., London.

Black Guard is a term used in the 16th century for the lowest menials of a noble house, the scullions who cleaned pots and pans. It was also used of the hangers-on of an army, camp-followers, then a rabble, vagabonds.

Black Gum. See **TUPELO.**

Black Hawk, a famous chief of the Sac and Fox Indians, born in 1767. He joined the British in 1812, and opposing the removal west of his tribe, fought against the United States in 1831-32. He died in 1838. There are Lives by Patterson (1834) and Snelling.

Blackhead, or COMEDO. See ACNE.

Blackheath, a high-lying open common in the metropolitan borough of Greenwich, to the south of Greenwich Park, 5 miles SE. of London. It commands a fine view, but is now not more than 70 acres in extent, many villas having encroached upon its margin. The Roman road to Dover crossed it. Blackheath was the first place in England where the ancient Scottish game of golf was introduced, most likely in 1608. On it stands Morden College, founded in 1695 by Sir John Morden for decayed Turkey merchants. Of schools innumerable, the chief is the Proprietary, established in 1830. Blackheath was formerly the scene of several insurrections, including those of Wat Tyler (1381), of Jack Cade (1450), and of the Cornishmen under Lord Audley (1497). Here, too, the Danes encamped in 1011; the Londoners welcomed Henry V. from Agincourt; and Charles II. on his way from Dover met the army of the Restoration. Blackheath was also a noted place for highwaymen. See Dr Drake's *History of Blackheath* (1886).

Black Hole, an appellation familiarly given to a dungeon or dark cell in a prison, and associated in the public mind with a horrible catastrophe in the history of British India—viz. the cruel confinement of a party of English in the military prison of Fort William, since called the 'Black Hole of Calcutta,' on the night of 19th June 1756. The garrison of the fort connected with the English factory at Calcutta having been captured by Suraja Dowlah (Siráj-ud-Daula), the nawab of Bengal, he caused the whole of the prisoners taken, 146 in number, to be confined in an apartment 18 feet square. This cell had only two small windows, and these were obstructed by a veranda. The crush of the unhappy sufferers was dreadful; and after a night of excruciating agony from crowding, heat, thirst, and want of air, there were in the morning only 23 survivors, the ghastliest forms ever seen on earth. But it should be remembered that Siraj had good reasons for attacking the English; and some of the best authorities hold that he was not aware of the condition and size of the prison. See, besides Holwell's narrative (1758) and Macaulay on Clive, *Old Fort William*, by C. R. Wilson (1906); *Bengal in 1756-57*, by S. C. Hill (1906).

Blackie, JOHN STUART, born in Glasgow in 1809, was educated at Aberdeen and Edinburgh, Göttingen and Berlin. In 1834 he published a metrical translation of Goethe's *Faust*, passed as advocate at the Edinburgh bar, and began to contribute to the magazines on German subjects. In 1841 he was appointed to the chair of Humanity in Marischal College, Aberdeen, which he held until 1852, when he was elected to the Greek chair in the university of Edinburgh. After he became professor he took an active part in promoting educational reform, and in the movement that led in 1859 to the remodelling of the Scottish universities. His incessant activity in lecturing and writing letters to the newspapers showed his marvellous vitality and the breadth of his sympathies. He always figured as the patriotic champion of Scottish nationality and its characteristic features, and advocated with equal ardour the preservation of things as dissimilar as old south-country customs and the Gaelic language. During the years 1874-76 he advocated throughout the country with great enthusiasm the found-

ation of a Celtic chair in Edinburgh University, and was successful in raising upwards of £12,000 for its endowment. He resigned his chair in 1882 to become a kind of peripatetic philosopher, expounding throughout Scotland alternately wit and wisdom, and the inalienable rights of the Highland crofter. He published a fine verse translation of *Æschylus* in 1850, another of the *Iliad* in ballad metre in 1856, as well as several volumes of verse. His prose works embrace moral and religious philosophy, the method of history, the law of laws, and a short life of Burns (1888). His principal philological papers were collected in *Horæ Hellenicæ* (1874). He died 2d March 1895. See the Life by Miss Stoddart (1895), and the shorter sketch by his nephew (1896).

Blacking is the material employed for producing a black glazed shining surface on leather. The main ingredient in the various kinds of blacking is Bone-black (q.v.), which is mixed with an oil, some sugar, and a little sulphuric acid. The materials in Day & Martin's blacking are finely powdered bone-black ground with sperm-oil, raw sugar or molasses, a little vinegar, and some concentrated sulphuric acid (specific gravity 1.843). The substances are incorporated together one by one in the order in which they are stated, and the action of the sulphuric acid is to convert much of the lime in the bone-black into sulphate of lime, which causes a thickening of the mixture, and a tenacious paste results. This paste, diluted with weak vinegar, is put, whilst warm, in stoneware bottles, and is then ready for the market. For harness the blacking consists mainly of beeswax, softened with turpentine, and mixed with ivory-black, Prussian blue, and copal varnish.

Black Isle is the common name for the peninsula in Easter Ross, lying between the Beaully and Moray Firths and Cromarty Firth. See ROSS-SHIRE.

Black Lead (or BLACKLEAD), GRAPHITE, or PLUMBAGO, a mineral consisting chiefly of carbon, but containing also more or less of alumina, silica, lime, iron, &c., to the extent of 1 to 47 per cent., apparently mixed rather than chemically combined. Black lead is the popular name, and that by which it is generally known in the arts, though no lead enters into the composition of the mineral; graphite is that generally preferred by mineralogists. It sometimes occurs crystallised in flat hexagonal tables; but generally massive, and more or less radiated, foliated, scaly, or compact. It is of a grayish-black colour, with a somewhat metallic lustre, and a black and shining streak, and is perfectly opaque. It is greasy to the touch, and is a perfect conductor of electricity. It occurs in beds and masses, laminae or scales in the schistose rocks (gneiss, mica-schist, clay-slate, &c.), and is sometimes in such abundance as to give its name to the schist (graphite-schist) in which it appears. It occurs also now and again in fissures in granite, or in scattered scales in various other igneous rocks, as in syenite in Norway, in porphyry in the Harz, in the Laurentian rocks of Canada. Thick vein-like masses of black lead are met with in Siberia, Spain, Bavaria, Japan, Ceylon, Mexico, and half-a-dozen widely separated localities in the United States and elsewhere; the once extensive supplies of Borrowdale in Cumberland are now exhausted. It is far more incombustible than even anthracite (or *blind-coal*), burning with much difficulty even before the blowpipe, on which account it is much used for the manufacture of crucibles or 'melting-pots,' which withstand a great heat. These are not, however, made of mere black lead, but of black lead in powder, mixed with half its weight

of clay. Black lead is used for making pencils; to give a black gloss to iron gates, &c.; and to diminish the friction of belts, machinery, and carriages. An artificial graphite is manufactured at Niagara Falls. See PENCILS.

Black Leg. See BLACK QUARTER.

Black Letter (~~Black Letter~~), the name which came into use about 1600, and is now commonly applied in this country to the types that on the Continent are most generally known as Gothic. The first printed books imitated every peculiarity of the contemporary manuscripts; and as printing was first practised in Germany and the Netherlands, the first types were copies of the letters in use in those countries in the middle of the 15th century. Two sorts of letters have been employed in the writings of Western Christendom. What have been called *Roman* letters prevailed from the 5th to about the close of the 12th century, when they gradually began to pass into what have been called *Gothic* letters, which continued till the 16th century, when, in most European countries, they were superseded by Roman letters. The first types, as has been said, were Gothic, and they spread with the art of printing into various European states. In France and Italy they were slightly modified by cutting off some of their rougher points; and when thus trimmed, they came to be known in the former country as *lettres de somme*, being so called, it is said, from then use in an edition of the *Summa* of St Thomas Aquinas. The classic taste of Italy could not long tolerate the Gothic character even of the *lettres de somme*; and they were still further modified, until they assumed the shape to which the name of Roman letters has since been given. The first works printed with these new types were two beautiful editions of Pliny's *Natural History*: the one by John of Spire at Venice in 1469; and the other by his disciple, Nicholas Jenson, also at Venice, in 1472. Another Venetian printer—the first Aldus Manutius—attempted in 1501 to supersede the Roman letters by what have been called *Aldine* (q.v.), or Venetian, but are best known as *Italic* characters. These can scarcely be said to have come into much more than temporary or exceptional use; but the Roman letters in no long time spread from Venice all over the west of Europe. Although thus supplanted in general use, the Gothic or black letter was long retained for special purposes, such as, in this country, the printing of Bibles, prayer-books, proclamations, and acts of parliament. Books in black letter being the earliest, are highly prized by antiquaries and bibliomaniacs, who are hence sometimes spoken of as 'black-letter devotees.' A form of the black letter still continues in general use in Germany; but about half of the books printed there are now in Roman letters. See PRINTING and TYPES. The 'Black-letter Saints' Days' of the Anglican calendar were printed in old calendars in black or ordinary letters, whereas the greater feasts were usually printed in red (hence Red-letter Days).

Black List, the name familiarly applied to printed lists connected with insolvency, bankruptcy, and other matters affecting the credit of firms and individuals, circulated for the private guidance of the mercantile community. The publication of such statements has frequently been made the ground of actions of damages in respect of injury done to financial credit. If, however, the statement is an accurate report of what took place in a court of law, it cannot be challenged as slanderous. On the other hand, any inaccuracy in the statement which injures a person's credit renders the publisher of the list liable in damages. The idea of furnishing to subscribers private lists of a more

searching kind is due to Mr Thomas Perry of Cornhill. In the United States the vast system of the mercantile agency and other similar institutions provides information of this kind; and printed lists of forgeries of bank-notes are issued. The term is also sometimes applied to persons convicted of habitual drunkenness. Under recent statutes, provision is made for the intimation of such convictions to occupiers of licensed premises. It is a punishable offence for the persons so convicted to purchase, or attempt to purchase, intoxicating liquors in licensed premises within three years after the conviction, and licence-holders are also prohibited, under severe penalties, from knowingly supplying liquor to persons declared to be habitual drunkards. In the United States the term 'black-listing' is generally applied to the practice of an employer furnishing other employers with the names of employees discharged by him. In many states there are enactments prohibiting employers from thus blacklisting employees with the intent of preventing their employment by others; but these enactments do not, as a rule, prevent an employer from furnishing to another a truthful statement of the cause of an employee's discharge.

Blacklock, THOMAS, D.D., the blind poet, was born of humble parentage at Annan in 1721, and lost his sight through smallpox before he was six months old. After going through the necessary course of academic study in Edinburgh, he was licensed as a preacher of the Established Church in 1759, and in 1762 was ordained minister of Kirkcubright. The congregation objected strongly to the appointment, and in 1764 he resigned the charge in consideration of a small annuity. After this he took pupils to board with him in Edinburgh till his death on 7th July 1791. It was a letter of his that arrested Burns on the eve of his departure for the West Indies. The first volume of his own poor poems appeared in 1746; and a collected edition was published in 1793.

Blackmail, a rent or tribute formerly exacted by freebooting chiefs from the people in the Border counties of England and Scotland, and along the Highland border. It was a kind of compromise with robbers, and bought immunity from the attacks not only of others, but also of those to whom it was paid. It is mentioned in Archbishop Hamilton's *Catechisme* (1552) and in Maitland's *Thievs of Liddesdale* (about 1561), and it continued to be exacted along the Highland border until about the middle of the 18th century. The celebrated Rob Roy was about 1730 a notable levier of blackmail in the southern Highlands and adjacent Lowlands. Later, Coll M'Donell of Barrisdale was noted farther north. For 'blackmailing' by threatening letters, see THREATS.

Black Monday, Easter Monday, 14th April 1360, so called from the extraordinary darkness and the fatally bitter cold.

Black Monks. See BENEDICTINES.

Blackmore, SIR RICHARD, court physician to William III. and Queen Anne, is remembered as the most heavy and voluminous of poetsasters. Born at Corsham in Wiltshire, he was educated at Westminster and Oxford, taking his B.A. in 1674. He was first a schoolmaster, then a London physician (1687–1722), and died at Boxted, Essex, in 1729. He seems to have been a good and well-meaning man, and the merciless ridicule of contemporary wits was due, in some part at least, to the moral and religious tone of his works, and to his free censures of the libertinism of the time. But the worthlessness of the poems has been amply confirmed by the judgment of posterity. *The Creation*, considered his best, Addison pronounces

'one of the most useful and noble productions in our English verse;' but few modern readers are likely to examine the grounds of this judgment, still less to agree with it. Blackmore wrote six epics in sixty books (choosing always the loftiest themes), besides versions of various books of the Bible, and theological, medical, and miscellaneous treatises.

Blackmore, RICHARD DODDRIDGE (1825-1900), novelist, was born at Longworth, Berkshire, and educated at Blundell's School (Tiverton), and Exeter College, Oxford. He graduated in 1847, afterwards studied law, was called to the bar at the Middle Temple in 1852, and practised for a time as a conveyancer. Ever long he united the pursuit of literature with the management of a market-garden and orchard at Teddington-on-Thames, and there he died 20th Jan. 1900. His first publications were *Poems by Melanther* (1854), *Epullus* (1855), *The Bugle of the Black Sea* (1855), followed by *The Fate of Franklin* (1860), and a translation of the first and second books of Virgil's *Georgics* (1862). Other volumes of verse have followed these, as well as a complete translation of the *Georgics* in 1871. His first novels were *Clara Vaughan* (1864) and *Cradock Novell* (1866), but his first distinct success was *Lorna Doone, a Romance of Exmoor* (1869), which reached a 38th edition in 1893. *Lorna Doone* is almost a great novel. The plot is good and well developed; the style has the quaint and pleasing flavour of its age, the time of James II., with Sedgemoor for its point of highest interest; and the figures have much more life and movement than in any other of his novels. His plots are usually defective in construction, and the human interest in his books is a much weaker element than that rare insight into and sympathy with inanimate life in which he stands alone among English novelists. He has described for us with absolute truth the Devonshire farmer as he lives and speaks; and many of his women, if somewhat shadowy in outline, are yet figures of rare tenderness and grace. His other novels are *The Maid of Sker* (1872), perhaps his second-best story; *Alice Lorraine* (1875); *Cripples the Carrier* (1876); *Erema* (1877); *Mary Anerley* (1880); *Christowell, a Dartmoor Tale* (1882); *Tommy Ugmore* (1884); *Springhaven* (1887); *Perilycross* (1894); *Tales from the Telling House* (1896); and *Daniel* (1897).

Blackness, on the Firth of Forth, once the port of Linlithgow, is now a very small village. Its castle, once important, has been in turns a state prison, an ammunition depot, and oil-station.

Blackpool, a watering-place, parliamentary and county borough of Lancashire, on the Irish Sea, 18 miles WNW. of Preston. The population has risen from 1664 in 1851 to 58,371 in 1911, 99,640 in 1921 (holiday season). It is one of the most frequented watering-places in the west of England, the sands being excellent, the views delightful, and the climate bracing. There are three fine piers, one of them with a splendid pavilion; a promenade extended by the Princess Parade in 1910-12; winter-gardens, an aquarium, a free library, and theatres. A tower of the Eiffel style, 500 feet high, with shops and entertainment rooms at the base, was erected in 1893-95.

Black Prince, the popular title conferred upon Edward (1330-76), eldest son of Edward III. (q.v.), perhaps referred to the colour of his armour. He went with his father to the Cotentin in 1346, and helped in the taking of Caen. At Crécy, where he was nominally in command of a wing, his part has been described as spectacular, but he played it heroically and with brilliant success. On the renewal of the war in 1355 he was given the

command in Aquitaine, where he restored English prestige, but diminished the English leanings of the inhabitants. After a brilliant raid in the south, he made an unsuccessful attempt to co-operate with the English forces in the north, but found it necessary, at Tours, to race against the French for the gap of Poitiers or be cut off from his province. The two armies lost each other. At Poitiers Edward found the French in possession, with, according to different estimates, three to seven times his numbers. But inferiority in tactics, an ill-judged combination of precipitancy and delay, and the refusal of the great lords to listen to good generals like Sir William Douglas turned what should have been an easy victory for the French into a crushing defeat, in which King John was taken. In 1361 the prince married his cousin Joan, the Fair Maid of Kent, widow of Sir Thomas Holland. In 1363 he returned to Aquitaine with the title of Prince of Aquitaine and Gascony. His expenditure there, always lavish, was increased by the Spanish campaign, in which he won the victory of Najera for the deposed Pedro the Cruel against his supplanter Henry de Trastamare and Du Guesclin. He taxed his subjects grievously to obtain the means of rewarding them richly. In particular the hearth tax (fouage) led to an appeal to the king of France, and in consequence to war. His province slipped gradually from his grasp, but before he retired to England, ruined in health and fortunes, he performed the last of his great achievements, the only one that certainly owed nothing to Sir John Chandos, the taking of Limoges. He ordered that all the inhabitants should be put to the sword, but relented after a few thousands had been slain. His ill-health did not prevent him from embarking on the Thouars expedition, which never reached France, or championing the Good Parliament in its onslaught upon Alice Periers a few weeks before his death. The prince was not only a model of chivalry, flawed with occasional ferocity, but as a tactician, strategist, and disciplinarian he has been placed above even Edward III., Du Guesclin, and Sir John Chandos. He was too much influenced by those immediately about him to be a good ruler, and his extravagant generosity and display kept him in trouble with creditors and taxpayers from his boyhood. See BADGE, ICH DIEN, and Life by Dunn-Pattison (1910).

Black-quarter, also known as Black-leg and Quarter-evil, is a contagious and infectious disease, due to the presence in the system of a specific micro-organism, the bacillus of black-quarter or *Bacillus chauvvei*, a small rod-shaped organism, aerobic and motile, which multiplies by sporulation. It is never found in the blood during life, but is plentiful in the tumours and effusions if examined soon after death. This disease is said to affect all ruminants, but is best known in cattle from a few months to two years old. It is less common than it was many years ago when it used to occur on some farms as an enzootic. This is thought to be due to better cultivation of the soil and improved farming.

Often the first thing observed is an animal standing apart with a dull depressed appearance and its back a little raised. When made to move it is found to be lame, and a hot painful swelling may be discovered about a thigh or quarter (hence the name quarter-evil) or elsewhere—if in the back or loins there will not be lameness, but a general stiffness. The temperature may be 105°, and there is generally constipation. The disease is practically uniformly fatal. After death the tumour is found to be almost black.

On farms where the disease was common the young stock were sometimes bled once, or even

twice, a year, and setons inserted in the dewlaps. Plenty of rock-salt should be within reach of the animals, and an occasional dose given of the sulphates of soda and magnesia with a little common salt and nitre. A vaccine, first prepared in France, from the tissue of the tumours is largely used on the Continent, and also in North and South America, perhaps more largely in the Argentine than anywhere, and there they have a firm belief in its efficacy. It can be obtained, and has been used, in Britain, but has not in all cases been an unqualified success.

Black Rod, GENTLEMAN-USHER OF THE, an officer of the House of Lords, appointed by letters-patent. He is chief gentleman-usher to the sovereign, and usher of the order of the Garter, at the chapter-meetings of which he keeps the door. He has charge of all arrangements for maintaining order in the House; takes into custody any peer guilty of breach of privilege; and (himself, or by his deputy the yeoman-usher) summons the House of Commons to the Peers when the royal assent is given to bills, or when royal speeches are read. If the sovereign is personally present in the Lords, he *commands*, but if royalty is represented by Lords Commissioners, he only *desires* the attendance of the Commons. The appointment of messengers, door-keepers, &c., rests with Black Rod. His title is derived from his wand, surmounted by a gold lion, which he carries instead of the mace.

Black Rood of Scotland. See HOLYROOD.

Black Sea, or EUXINE (the *Pontus Euxinus* of the ancients), is an inland sea lying between Europe and Asia, extending from 41° to 46° 38' N. lat., and from 27° 30' to 41° 50' E. long. Its greatest length from east to west, on the 42d parallel, is 720 miles; its greatest breadth, near the west end, 380 miles; and its area, exclusive of the Sea of Azov, is 163,711 sq. m., according to Strelbitsky. On the south-western extremity it communicates by the Bosphorus, the Sea of Marmora, and the Dardanelles, with the Mediterranean, and on the north-east by the Straits of Kerch, or Yenikale, with the Sea of Azov. The Black Sea drains nearly one-fourth of the surface of Europe, and also about 114,000 sq. m. of Asia. Throughout its whole extent it has but one island, and that a small one, lying opposite the mouths of the Danube, called *Adassi*, or Isle of Serpents, on which is a lighthouse. In the centre its depth ranges between 1000 and 1070 fathoms, and as there are no shoals along the shores, except at the entrance of the Bosphorus, the navigation of the sea ought to be particularly easy and safe. It is so in summer; but in winter, being inclosed on every side, it becomes the scene of conflicting winds, and of storms which, though of short duration, are terrible while they last.

All the coasts are high, with good harbours, except between the mouths of the Danube and the Crimea; there the land is low, and the danger of navigation greatly increased in winter by the presence of floating ice; for, from the many large rivers which flow into this sea and that of Azov (Danube, Dniester, Bug, Dnieper, Don, Kuban, and Rion, in Europe; and the Kizil-Irmak and Sakaria, in Asia), the waters are fresher, and consequently more easily frozen than those of the Mediterranean. The specific gravity of the water of the Black Sea is 1014 (fresh water being = 1000), while that of the Mediterranean is 1028. The shores from Odessa to the Crimea are ice-bound during January and February; and although the harbour of Odessa is never frozen up, yet the drift-ice frequently renders the entrance to it dangerous.

There is no tide in this sea, but the large rivers

flowing into it give rise to currents, which are particularly strong in spring when the snows melt. There is a strong flow out through the Bosphorus.

The most important ports on the Black Sea are Constantza, Sulina, Odessa, Nikolaiev, Kherson, Eupatoria, Ketch, Sebastopol, Poti, Batum, Trebizond, Samsun, Sinope, and Varna.

The depth of the water is unfavourable to the extensive establishment of fisheries, but sturgeon are caught in the Straits of Yenikale, and other fish are abundant.

The ancients believed that the Euxine was at one time much more extensive, and that it had no connection with the Mediterranean, until the Thracian Bosphorus had been burst through by an earthquake, or by the great deluge known as the Deucalion deluge, which inundated Greece.

The sea has been navigated from a very early period. Its original Greek name was *Axeinos*, or 'inhospitable' sea, afterwards changed euphemistically to *Euxenos*, the 'hospitable.' In the time of Xerxes large quantities of corn were exported from its ports to Athens and the Peloponnesus. The Romans and Byzantines, and also the Genoese, had large traffic on the sea. From the fall of Constantinople (1453), all but Turkish vessels were excluded from its waters, until the treaty of Kainardji (1774), when the Russians obtained the right to trade in it. Ten years after, Austrian ships were privileged to trade here; and by the Peace of Amiens in 1802 British and French ships were admitted. It was entered by the allied fleets, at the requisition of the Porte, in January 1854, and a dreadful storm in November of the same year caused great loss of life, shipping, and stores. By the Treaty of Paris (1856) it was opened to the commerce of all nations, and closed to ships of war, while the erection of arsenals was forbidden; but this article was repudiated by Russia in 1870, and in the following March, at a conference in London, the neutralisation of the sea was abrogated. Russia and Turkey thenceforward kept fleets in its waters. The Bosphorus and Dardanelles were to be closed to ships of war other than Turkish, the sultan having power to open them to allies. But see BOSPORUS.

Black Snake (*Bascanium constrictor*, see COLUBER), a species of snake common in the United States of America from Louisiana to Connecticut. Barring the white throat, it is of an almost uniform leaden colour, is one of the largest serpents in North America, and is remarkable for its great agility. It moves along the ground with a swiftness equal to that of a horse, glides over bushes, and climbs trees. It feeds on small quadrupeds, birds, frogs, &c.; frequently plunders poultry-yards of eggs; and enters dairies to drink milk or cream. A persistent enemy of the rattlesnake, it is generally the conqueror in a struggle, enveloping its venomous foe in its coils and crushing it to death. It has no poison-fangs, but is not slow to bite. It is easily tamed.—One of the commonest Australian snakes (*Pseudochis porphyriacus*), found in marshy places, and somewhat cobra-like in its actions, is also called the Black Snake. The back is glancing black, the sides carmine, the belly red; the neck is not dilatate. It may measure over 6 feet in length. It is very venomous, belongs to the family Elapidæ, and is nearly allied to the Cobra (q.v.).—In Victoria and Tasmania the name is given to several species of Hoplocephalus.

Blackstone, SIR WILLIAM, a silk-mercier's posthumous son, born in London 10th July 1723, from the Charterhouse passed to Oxford, and was elected a fellow of All Souls; from the Inner Temple he was called to the bar, but failed to attract notice. In 1749 he succeeded an uncle

as recorder of Wallingford, in Berkshire; and in 1753 he delivered a course of lectures at Oxford on the law of England. Three years later, a Mr Viner having left £12,000 to endow a chair of English Law at Oxford, Blackstone was in 1758 appointed first Vinerian professor. Next year he returned to Westminster; and as the doctrines which he had taught as a lecturer had commended him to the Tory government of that day, he was made a king's counsel in 1761, in the same year becoming member for Hindon, in Wiltshire, and shortly after principal of New Inn Hall, Oxford. Other honours followed fast, and in 1763 he was made solicitor-general to the queen. In 1765-69 he published the four volumes of his lectures, which form his celebrated *Commentaries on the Laws of England*, and which brought him in £14,000. His practice, too, continuing to increase, he resigned in 1766 his Oxford appointments. Four years later he declined the solicitor-generalship, and, having been knighted, was made a justice of the Court of Common Pleas. He died 14th February 1780, and was buried at Wallingford.

Blackstone's fame rests wholly on his *Commentaries*. His seventeen other literary works, which included some youthful poetry, were inconsiderable, and his merits as pleader or judge were not of themselves such as to have made his reputation outlive him. As a commentator, he had many excellences. His style is in general clear and gracefully ornate, his illustrations are pleasing and felicitous. While he confined himself to exposition—to the accurate statement in scholarlike English of what had heretofore lain buried in the cumbersome language of lawyers like Littleton—Blackstone was unsurpassed, and rendered an important service to the country. But he was ambitious of combining with this exposition the higher task of explaining the reasons of law, as well as its merits and defects. For this survey of law from the legislator's point of view, he had not the requisite qualifications; his knowledge of English history was superficial, his study of the philosophy of law had been imperfect. With the works, indeed, of Montesquieu and Beccaria he was acquainted; but the mode in which he quotes them shows that he had imbibed nothing of their spirit. The method followed in the *Commentaries* was unscientific, and was taken from Sir Matthew Hale's *Analysis of the English Law*. But the comprehensiveness and accuracy of the work and its dignity of style made it in some respects the most influential treatise on English law. Innumerable editions of it have been published up till the 20th century; and all subsequent commentaries on the law of England, as well as those of Kent in America, were based on it.

Black Stream. See JAPAN (*Climate*), PACIFIC OCEAN.

Blackthorn. See SLOE.

Blackwall, a London district in the borough of Poplar, at the junction of the Lea with the Thames, $3\frac{1}{2}$ miles ESE. of St Paul's. It has foundries, shipbuilding yards, East and West India Docks, and a tunnel under the Thames (opened in 1897).

Black Watch (Gaelic *Frèiseadan Dubh*), the first of the Highland regiments, had its origin in a commission granted to John, second Earl of Athole, in 1668, 'to raise and keep such a number of men as he shall think fitt' to be a constant guard for securing peace in the Highlands. The term *black* arose from the dark colour of their tartan uniform, which distinguished them from the regular troops, called the *Saighdean Dearg*, or 'red soldiers.' From 1704 till the Union,

there were three companies in existence directly dealt with by the Treasury in regard to pay and clothing, and wholly armed with firearms. In 1729 the companies were six in number—three comprising 100 men each, commanded by captains, and three of 70 men each, commanded by captain-lieutenants. The body was raised chiefly from the Whig or loyal clans—Campbells, Grants, Munros, &c. The duties of the Black Watch were to enforce the disarming act, to prevent political meetings of a seditious kind, and to check depredation. After being of considerable use for these local purposes, the whole of the companies were formed into the 42d Regiment, under the command of the Earl of Crawford, in 1739; and in 1743 the regiment joined the troops in Flanders, and first went into action at Fontenoy, since when it has been one of the most distinguished corps in the British army. As it was embodied under a Lowlander, it was necessary to adopt an arbitrary pattern of tartan, which has ever since been known as the 42d or Black Watch tartan. When in 1881 the numerical designations of the British foot regiments were dropped, the former 42d and 73d Regiments were made respectively first and second battalions of the 'Black Watch (Royal Highlanders).' See HIGHLANDS; Forbes, *An Historic Regiment* (1896); and Ross in Lady Tullibardine's *Military History of Perthshire* (1908).

Black Water, RED WATER, MUIR-ILL, or HÆMO-ALBUMINURIA, a disease of cattle, best known as occurring in cows from ten to fourteen days after calving. The first symptom usually observed is a dark appearance of the urine, which comes away in a small stream and causes a heap of froth where it falls. As a rule this is accompanied by diarrhoea. On examination it is found that the pulse is more frequent and very distinct—very easily felt. The heart can sometimes be heard beating by one standing beside the animal. The diarrhoea is soon followed by constipation; the urine becomes darker, passing through red to brown, and sometimes even black; the appetite gradually fails; the secretion of milk diminishes, and if it be left standing in a vessel and then poured off slowly and gently, a red deposit will be found at the bottom.

It is a very fatal disease, and most frequently met with on poor badly drained soils. Whatever the cause the blood corpuscles are broken up and passed off by the kidneys, albumen and the colouring-matter of the blood being found in the urine.

A purgative should be given early while diarrhoea is present, with soft nourishing nitrogenous food, and when the appetite fails raw eggs and milk, with astringents and stimulants, as strong ale or porter. Post-mortem examination reveals bloodlessness, with a yellowish tinge of the tissues.

Blackwater, or HÆMOGLOBINURIC or HÆMATURIC FEVER, is an acute disease with feverishness, bilious vomiting, jaundice, and the passage of red or dark-brown urine. It affects persons of all colours in tropical Africa, both on the east and west coasts, and from the Upper Nile to Rhodesia. To a less extent it occurs also in the southern states of the Union, in Greece, and in some of the East Indian Islands. The cause is still somewhat uncertain. It is found in places where malaria is rife, and used to be regarded as a bad type of malaria. Later it was suggested that, though occurring in malarious subjects, it was really due to the destructive action on the red blood corpuscles of prolonged dosage with quinine. Still more recently it is believed to be due to an unknown poison, spread under the same conditions as the malaria parasite. The mortality is about 25 per cent. of all cases. In treatment careful nursing

is all-important, and large quantities of fluid should be given.

Blackwater, the name of numerous rivers and rivulets in Great Britain and Ireland, of which the longest are: (1) The Blackwater of Munster, 100 miles in length, which enters the sea at Youghal harbour; (2) the Blackwater of Ulster, 50 miles long, which falls into the south-west corner of Lough Neagh; and (3) the Blackwater of Essex, 40 miles long, which falls into the North Sea.

Blackwell, ALEXANDER, adventurer, seems to have been born in Aberdeen about the beginning of the 18th century, and to have been a younger son of the Rev. Thomas Blackwell (1660-1728), principal of Marischal College. He may, or may not, have studied medicine under Boerhaave at Leyden; anyhow, about 1730, he was a printer in London, and becoming bankrupt in 1734, was supported in prison by his wife, who published a *Herbal* (2 vols. folio, 1737-39) with 500 cuts of plants, drawn, engraved, and coloured by herself, her husband adding their Latin names, with a brief description of each. Next, in 1742, Blackwell turns up in Sweden, where, having cured the king of an illness, he was appointed one of the royal physicians, and undertook the management of a model farm. While still in the full enjoyment of court favour, he was charged with being concerned in a plot against the constitution, and after being put to the torture, was beheaded, August 9, 1747, protesting his innocence to the last.

Blackwell, ELIZABETH, the first woman that obtained a medical diploma in the United States, was born at Bristol in 1821. Her family emigrated to the States in 1832, and six years later the father died, leaving a widow and nine children. Elizabeth helped to support the family for some years by teaching, steadily devoting her leisure the while to the study of medical and anatomical books. At last she was permitted to enter the medical school of Geneva, N.Y., and to graduate in 1849. She thereafter lectured, wrote, and established a dispensary. In London she lectured on medicine as a profession for women, encouraged Drs Elizabeth Garrett Anderson and Jex Blake, and held a chair of gynaecology in the London school for women. She died in June 1910. She was much assisted by her sister Dr Emily Blackwell (1826-1910). See her autobiographical *Pioneer Work* (1895; new ed. 1914).

Blackwell, GEORGE. See ARCHPRIEST.

Blackwell, THOMAS, scholar, a brother most likely of Alexander Blackwell (q.v.), was born at Aberdeen in 1701, and took his M.A. in 1718. In 1723 he was appointed professor of Greek in Marischal College, and in 1748 its principal. He died at Edinburgh, 8th March 1756. He was author of *Inquiry into the Life and Writings of Homer* (1735), *Memoirs of the Court of Augustus* (3 vols. 1752-64), and two or three other works.

Blackwood, or BLACVODÆUS, ADAM (1539-1613), an adversary of Buchanan and champion of Queen Mary and authority, was born at Dunfermline, and lived mostly at Poitiers.

Blackwood, WILLIAM, a distinguished Edinburgh publisher, the originator of *Blackwood's Magazine*, was born in Edinburgh, November 20, 1776. After serving his apprenticeship to the book-selling business in his native city, and prosecuting his calling in Glasgow and London, he settled in Edinburgh as a bookseller—principally of old books—in 1804. In 1817, having six years before become a publisher on his own account, he issued the first number of *Blackwood's Magazine*. The literary ability displayed in this periodical was so much in advance of the monthly magazines then existing, that from the first it was a great success. Its

remarkable popularity was sustained by the papers of Wilson ('Christopher North'), Lockhart, Hogg, and other spirits, whom Blackwood had the liberality and tact to attract to his standard. Overwhelming its political and literary opponents, now with the most farcical humour, and now with the bitterest sarcasm—sometimes with reckless injustice—the magazine secured for itself a prodigious reputation, more particularly among the Tories, of whose political creed it has always been a resolute adherent. William Blackwood himself, who added literary tastes and acquirements to his profession of a bookseller, was the chief manager of his magazine, and conducted the whole of the correspondence connected with it until his death, which took place September 16, 1834. His place was filled, between 1834 and 1852, by his sons, Alexander and Robert, the early death of the former cutting short a career of great promise. Under John (1818-79), the third son, who was editor from 1852, *Maga* not only sustained but increased its reputation. The publishing business has been greatly extended since the days of the founder of the house, 'George Eliot's' novels having all but one issued hence.

See Mrs Oliphant's *Annals of a Publishing House* (1897) and Sir George Douglas, *The Blackwood Group* (1897).

Bladder (urinary) is a hollow bag for the reception of the urine. When moderately distended it has a capacity of about a pint, but under various conditions it is capable of holding far more. Thus, the bladder of a drunkard has been seen so dilated that it held twenty pints, and when completely paralysed there is no limit to its distension. Instances of very large bladders are not infrequent in females, but this is probably the result of over-distension, and not due to the female bladder being naturally larger than that of the male. Indeed, competent authorities state that the reverse is the case.

In all young animals possessing a bladder, it is elongated in form, indicating that originally it was a tube. In an infant it is pear-shaped—the condition which is permanent in quadrupeds; but as man gradually assumes the erect attitude, the lower part expands under the weight of the urine. In the adult, its size, shape, position, and relations to surrounding organs vary according to its state of collapse or distension. When empty it sinks deeply into the pelvis, and appears flattened above and below; when moderately full its form is rounded, but still it remains within the pelvis; when completely distended it projects above the brim of the pelvis, becoming an abdominal organ, and having an ovoid or egg-shaped outline. It now presents a base or larger end directed backwards, an apex or summit—the smaller end—directed upwards and resting against the lower part of the anterior abdominal wall. At the front of the base, the urethra, which leads off the urine, commences abruptly in a thickened portion named the neck. At this point the bladder is fixed to the walls of the pelvis by fibrous bands named true ligaments. In all other directions it is freely movable, although receiving support from surrounding parts such as rectum or vagina, according to the sex, also to a slight extent from blood-vessels and the two ducts from the kidneys (ureters), and lastly from the peritoneum, which, on account of its various reflections from the organ, forms folds known as the false ligaments. The wall of the bladder consists of several layers or coats, in which blood-vessels and nerves ramify. The outer coat is formed of peritoneum, which only partially invests the bladder, being found on its upper and posterior half. The next coat consists of bundles of muscular fibres arranged in various directions. Between this and the lining membrane there is a well-marked layer consisting of areolar tissue, in which the

blood-vessels ramify, and named the vascular or *submucous coat*. The lining membrane (*mucous coat*) is soft and smooth. It is continuous with the lining membrane of the ureters and that of the urethra. Being loosely attached, it is nearly everywhere thrown into wrinkles, which disappear as the bladder is distended. If an imaginary line be drawn between the openings of the ureters, and from each end of this line others be drawn to the orifice of the urethra at the neck of the bladder, a triangular portion of the base will be mapped out, having its apex pointing forwards, and each side measuring about an inch and a half. Within this area, to which the name *trigone* is applied, there are never any wrinkles, even when the bladder is empty, because the mucous coat adheres more closely to subjacent parts. This area has a greater number of blood-vessels and nerves than other parts of the bladder, and therefore possesses more acute sensibility. As the urine accumulates in the bladder, its pressure on the trigone gives rise to the feeling of a full bladder and the necessity for micturition. The intense pain produced by stone in the bladder is due to the same cause (see CALCULUS). As the bladder becomes distended, its muscular walls begin to contract periodically upon the fluid contents; so do the muscular fibres which surround the outlet of the bladder—viz. the urethra. As long as the pressure within the bladder is not very high, the latter is able to resist the former, as is seen during sleep; but after a certain stage of distension is reached, the contractions of the bladder wall overcome those of the fibres closing the urethra, and the bladder is emptied. This process occurs naturally in young children, but as age advances the fibres surrounding the outlet of the bladder come under the control of the will, and thus the urine can be voluntarily retained or expelled. The bladder is liable to catarrhal inflammation of the coats, to paralysis, and other affections. Rupture of the bladder by accident is usually fatal. For incontinence of urine and retention of urine, see URINE. There is no urinary bladder in birds (see BIRD).

In general *zoological* usage, the term bladder is applied (1) to that outgrowth from the dorsal surface of the gut which forms the Air- or Swim-bladder (q.v.) of many fishes, and serves in a few cases as an incipient lung; and (2) to the urinary bladder. It is necessary to note, however, that the latter may have a very different origin in different animals. (a) In the gristly fishes the terminal extremities of the so-called 'Wolffian ducts' coalesce to form a urinary cloaca, which opens into the general cloacal chamber. (b) In the bony fishes the urinary bladder is a dilatation at the exit of the ureter. (c) In amphibia the bladder arises as an outgrowth from the hind-gut, and represents the allantois of higher animals. (d) In reptiles the stalk of the allantois dilates to form a permanent urinary bladder, which is absent in birds. (e) In mammals the stalk of the allantois again dilates to form the bladder.

Bladder Campion. See *SILENE*.

Bladder-cherry (*Physalis alkekengi*). See WINTER-CHERRY.

Bladder Green is derived from the Buckthorn (q.v.).

Bladder-nut (*Staphylea*), a very widely distributed genus of deciduous shrubs or small trees of rather elegant appearance, of the order Staphyleaceæ, allied to Celastraceæ. The Common Bladder-nut (*S. pinnata*) is frequently planted in shrubberies, as is also the North American *S. trifoliata*. The wood of both is firm and white, well suited for the purposes of the turner. The seeds yield a good oil, and may be eaten, but act as a mild aperient. The flower-buds are

pickled as capers. The name bladder-nut has reference to the curious inflated membranous

Common Bladder-nut (*Staphylea pinnata*):
a, a flower; b, fruit.

capsule, and the hard bony *testa* of the seed. The name *Staphylea* is from the Gr. *staphylē*, 'a bunch of grapes,' and has reference to the racemed flowers.

Bladder-seed (*Physospermum cornubiense*), an umbelliferous weed, noted for its inflated fruit.

Bladder-senna (*Colutea arborescens*), a leguminous tree of Southern Europe, occasionally planted in sheltered shrubberies. It owes its name partly to the dry inflated pod, partly to the tradition of the use of its leaflets for adulterating senna.

Bladder-worm, the asexual stage of a tape-worm or cestode. It is found encysted in a host which is likely to be eaten by the final host of the tapeworm. The stage owes its name to the bladder-like form resulting from the encysted embryo. Within the bladder a 'head' is developed (a in fig.), which is eventually turned upwards, and retains the bladder as a sort of appendage (b in fig.). In exceptional cases (see HYDATIDS) the bladder buds off internally, not one head but many. On passing to the final host the bladder-worm loses its bladder, and the head or scolex, becoming attached to the gut, buds off the familiar chain of 'joints,' which gradually become sexually mature. Before the life-history of cestoid parasites was understood, the bladder-worms were described as separate organisms, but they are now known to be simply the asexual stages of an 'alternation of generations.' Thus the *Cysticercus cellulosæ* or bladder-worm of the pig becomes the *Tænia solium* or tapeworm of man; the *C. mediocanellata* of ox, the *T. saginata* of man; the *C. fasciolaris* of the mouse, the *T. crassicolis* of the cat; the *Cenurus cerebralis* of the sheep, the *T. cenurus* of dog; the *Echinococcus* of man, the *T. echinococcus* of dog, and so on. The bladder-worm is more passive, vegetative, and entirely asexual; the tapeworm

Bladder-worm.

joint is more active, its nutrition probably more stimulating and variable, its reproduction sexual. See CESTOID WORMS, TAPEWORM.

Bladderwort (*Utricularia*), a genus of Lentibulariaceæ, which like its congener the Butterwort (q.v.) is remarkable for its carnivorous habit. The two hundred species are often aquatic or floating, the leaves frequently floating, and divided, the flowers generally yellow. The stems and leaves bear the characteristic animal-catching pitchers. See INSECTIVOROUS PLANTS.

Bladensburg, a village of Maryland, on the east branch of the Potomac, 6 miles N.E. of Washington by rail. It was here that the battle which decided the fate of the capital was won by the British on the 24th August 1814.

Blaeberry. See WHORTLEBERRY.

Blaes, a Scottish miners' name for the shale of the coal-measures, originating apparently from the 'blae' or bluish colour sometimes noticed in the shale. The term is occasionally used by geologists.

Blaeu (spelt also *Blaeuw* and *Blauw*, Lat. *Cassius*), WILLEM JANSZON, a map-drawer and printer, was born at Alkmaar, Holland, in 1571. His Terrestrial and Celestial Globes excelled in beauty and accuracy everything that had preceded them; as also did some of his maps. He died in 1638. —His son, JAN (died 1673), commenced business on his own account at Amsterdam in 1637, but afterwards entered into company with his brother, Cornelis (died 1650). His *Atlas Major*, in 11 volumes, is a remarkable work, with many curious plates; and the maps are extremely valuable from the light they throw on local history. Besides six maps of Ireland, the volume on Scotland contains forty-nine maps of that country, prepared by Timothy Pont (q.v.), and a great amount of local details by Sir John Scott. He further published a series of topographical plates and views of towns. Two of Jan's sons carried on the business until 1700.

Blagodät, a hill (1260 feet) in the Urals, about 150 miles E. of Perm, is very rich in magnetic iron ore.

Blagovestschensk, or BLAGOVYESTCHENSKA, a town of south-eastern Siberia, capital of the Amur Province, at the confluence of the Amur and Seja rivers, with some manufactures, and 80,000 inhabitants. During the Chinese troubles in 1900 there was fighting on this frontier; and many Chinese (report said thousands) were said to have been 'massacred' or forced into the river by the Russians at Blagovestschensk.

Blaine, JAMES GILLESPIE, born at West Brownsville, Penn., in 1830, taught in a Kentucky military institute, and in the Pennsylvania institution for the blind. In 1854 he settled as a journalist at Augusta, Maine, and served in the state legislature from 1858 to 1862; from 1862 to 1876 he sat in congress, being Speaker in 1869-74. He was defeated in the Republican nominations for the presidency in 1876, 1880, 1884, and 1892. Senator for Maine in 1876, he acted as Secretary of State under Garfield, and again under Harrison (till 1892). He died January 27, 1893. He was the author of *Twenty years of Congress* (2 vols. 1884-86).

Blainville, HENRI MARIE DUCROTAY DE, zoologist and anatomist, was born in 1778, near Dieppe, studied medicine and the physical sciences at Paris, and in 1812 was appointed assistant-professor of Comparative Zoology, Anatomy, and Physiology, in the university, as well as professor of Natural History at the Athenæum; in 1825 a member of the Institute; and in 1832 successor of Cuvier in the chair of Comparative Anatomy in the Museum of Natural History. He died May 1,

1850. Blainville achieved great success, not only as a teacher, but as the author of *Faune Française* (1821-30), *De l'Organisation des Animaux* (1822), *Cours de Physiologie Générale et Comparée* (1833), *Ostéographie* (1839-64), &c.

Blair, HUGH, was born at Edinburgh in 1718, and in 1730 entered the university, where his *Essay on the Beautiful* gave his preceptors a high idea of his ability and taste. In 1741 he was licensed as a preacher, and after occupying the churches of Collesie in Fife, Canongate, and Lady Yester's, he was promoted in 1758 to one of the charges of the High Church, Edinburgh. His discourses, which display little power or originality of thought, and which derived nothing from the delivery of their author, were greatly admired by 'persons of the most distinguished character and eminent rank' in Scotland on account of their polished style. In 1759 he commenced a series of lectures on *Composition* to classes in the university; and in 1762 he was appointed to a new regius chair of Rhetoric and Belles-lettres, with a salary of £70 a year. He resigned this post in 1783, and in the same year published his *Lectures*, which obtained a reputation far beyond their merits, and one that time has by no means confirmed. His *Sermons* (1777) enjoyed the approval not only of Dr Johnson, but of George III., who showed his appreciation by bestowing on Blair in 1780 a pension of £200 a year. Blair also published three other volumes of *Sermons*, and a fourth appeared after his death, which took place December 27, 1800. They were all as successful as the first. Opinion about their merits has much changed since the date of their publication; they are now considered as moral essays rather than sermons. Blair's critical acumen was not great; he strenuously defended the authenticity of Ossian's poems.

Blair, ROBERT, author of *The Grave*, was born in 1699 at Edinburgh, where his father was a clergyman. There and in Holland he was educated for the church, and in 1731 he was ordained minister of Athelstaneford, Haddingtonshire, where he lived in easy circumstances till his death 4th February 1746. He was an accomplished and thoughtful man, devoted considerable attention to natural science, particularly botany, and corresponded on friendly terms with several eminent contemporaries, among others, Watts and Doddridge. To them in 1742 he submitted the MS. of his poem, which Watts offered to two publishers. They thought it too heavy for the times, and it did not appear till 1743. It speedily attained an honourable place in the esteem of those capable of appreciating a masculine, though somewhat gloomy force of thought and imagery, applied to a profoundly suggestive and serious theme. In William Blake it found a congenial illustrator. Blair was succeeded in his ministerial charge by Home, the author of *Douglas*. His third son, Robert Blair, of Avontoun (1741-1811), became Lord President of the Court of Session.

Blair-Atholl, a Perthshire village, situated at the confluence of the Garry and Tilt, 20 miles NNW. of Dunkeld. Blair Castle, the seat of the Duke of Atholl, dates in its oldest part from the 13th century, and as restored in 1872 is a fine baronial structure. It has many memories of sieges and royal visits, from Queen Mary's days to Queen Victoria's. Claverhouse was buried in the old church of Blair.

Blairgowrie, a town of Perthshire, very picturesquely situated on the right bank of the Erich, 20 miles NNE. of Perth by a branch line (1855). It has flax spinning and weaving factories driven by the Erich. Much fruit is grown. Pop. 3000.

Blaize. See BLASIUS.

Blake, ROBERT, next to Nelson the greatest of English admirals, was born at Bridgewater, the eldest of the twelve sons of a merchant there, in August 1599. From the grammar-school of his native town he passed in 1615 to St Alban's Hall, and shortly afterwards to Wadham College, Oxford, where he remained till 1625. He seems next to have continued his father's business, and to have prospered, but may from time to time have himself made voyages to distant seas, as prosperous merchants at that time very often did. He led the life of a quiet country gentleman until he had reached his fortieth year, and was returned for Bridgewater to the Short Parliament of 1640, that preluded the Civil War. He cast in his lot with the parliament without hesitation, but did not become a member of the Long Parliament till 1645. An ardent Republican, and a man of blunt, straightforward manners, singularly devoid of fear, and of inflexible character, he was much respected by Cromwell, but he never became personally very intimate with him. He served under Popham in Somersetshire, and attracted notice by his conduct at the siege of Bristol, and his obstinate defence of Lyme, in Dorsetshire, in 1644 against Prince Maurice. His defence of Taunton for nearly a year against overwhelming odds, when the town was little more than a heap of ruins, covered him with fresh glory, and proved a turning-point in the war.

In 1649 he was appointed with two others to command the fleet, at that time in a state of disaffection and weakness. Before two years he had blockaded Lisbon, destroyed the squadron of Prince Rupert, and forced the royalists to surrender the Scilly Isles and Jersey, their last stronghold. Early in 1652 began the struggle with the Dutch for the supremacy of the seas, and Blake found himself pitted against such redoubtable seamen as Van Tromp, De Ruyter, and De Witt. In the first engagement on the 19th May, though his fleet numbered over forty ships to Blake's fifteen, Van Tromp retreated under cover of darkness with the loss of two ships. It is right to add that the English ships were larger than the Dutch, and their artillery superior. On the 28th September Blake gave battle to De Ruyter and De Witt off the mouth of the Thames, both fleets about sixty-five ships in number. The fight ended with the flight of the Dutch next day. On the 29th November a fleet of eighty vessels under Van Tromp encountered Blake with scarcely forty off the Goodwin Sands. After a two days' hotly contested fight, victory remained with the Dutch. Blake lost six of his ships, but brought the remainder in a sadly shattered state into safety. In his report to the council of state he complains of the 'baseness of spirit, not among the merchantmen only, but many of the state's ships.' Van Tromp now scoured the Channel in triumph, and to this period belongs the apocryphal story of his having tied a broom to his mast-head. Blake asked to be released from his command, but by the middle of February 1653, he was again at sea with nearly eighty ships. On the morning of the 18th Van Tromp was sighted near Portland with about an equal force. A long running fight at once began, and lasted from Portland to Calais. Blake was severely wounded, but gained a complete victory, sinking five ships and capturing four, as well as over thirty merchantmen in Van Tromp's convoy. His ill-health prevented him from taking part in the engagement of the 31st July, which finally shattered the naval supremacy of Holland. In September 1654 he sailed with a fleet to the Mediterranean, and he soon made the English flag respected at Cadiz, Naples, and Leghorn alike. In April 1655 he sailed under the guns of Tunis, a nest of pirates, and burned a fleet of nine ships. He next sailed to Algiers, where the dey in terror

submitted to his terms. At the approach of winter he returned to England, but early in the spring of 1656 was cruising again off Cadiz. In September, Stayer, one of his lieutenants, fell in with the Plate fleet and captured it—a loss to Spain of nearly two millions in treasure alone.

But the crowning exploit of Blake's career was his last. Hearing early in April 1657 that a fleet from America had arrived at Santa Cruz de Teneriffe, he at once sailed thither, and on the morning of the 20th arrived in the bay where there were sixteen ships lying at anchor, 'moored close along the shore, which lies in a semicircle, commanded as far as the ships lay by the castle, and surrounded besides with six or seven forts.' Before night he completely destroyed the fleet and the town, and contrived to draw off, owing to a favourable change of wind, with a loss of 50 slain and 120 wounded. The wonderful daring and success of this exploit excited the utmost enthusiasm throughout England, and admiration throughout Europe. But it was the last of the great admiral's glories. With health fast failing, he returned homewards to die just as his ship entered the harbour of Plymouth, 7th August 1657. Cromwell honoured his memory by a stately funeral, and caused him to be interred in Westminster Abbey, whence the body was ousted at the Restoration. A window to his memory was placed in St Margaret's, Westminster, in 1888. Blake's skill and courage were equalled only by his disinterested patriotism, sterling honesty, and love of justice; he not only gained a decided superiority over England's mightiest naval opponent, but, by the boldness and novelty of the tactics he introduced, taught English seamen to attempt every enterprise, however difficult and doubtful, with the same reckless and easy daring. See Hannay's *Admiral Blake* (1886) in 'English Worthies.'

Blake, WILLIAM, engraver, painter, and poet, was born in London on the 28th of November 1757, the son of a hosier. He was a dreamy boy, addicted to drawing and verse-making, and fond of solitary rambles in the country, during which he believed that he saw visions of angels in the sky and among the trees. At the age of ten he began to study art in Par's Academy in the Strand, and four years later he was apprenticed to James Basire, the engraver, in whose antiquarian prints he assisted, and for whom he executed drawings from the ancient monuments in the churches of London and its neighbourhood. His apprenticeship ended in 1778; and, after studying in the Antique School of the Royal Academy, he began to produce water-colour figure-subjects, and to engrave illustrations for the *Ladies' Magazine*, and, after Stothard, for the *Novelists' Magazine*. His first picture exhibited in the Royal Academy was 'The Death of Earl Godwin,' shown in 1780. His leisure had from early years been devoted to the composition of poems, of which the first volume, the *Poetical Sketches* by W. B., published in 1783, is full of true pastoral feeling and of an exquisitely spontaneous lyrical power. This work, with the *Songs of Innocence* (1789), and the *Songs of Experience* (1794), include the finest examples of Blake's poetry, for the so-called 'Prophetic Books'—the *Book of Thel* (1789), the *Marriage of Heaven and Hell* (1791), *The French Revolution* (1791), *The Song of Los* (1795), and many others—are strangely mystical and unintelligible, their text being usually interwoven with imaginative designs. In 1906 Mr Sampson for the first time printed the text verbatim from the poet's MS.

All his poetical works, with the exception of the *Poetical Sketches* and *The French Revolution*, were produced in a method peculiar to the

artist himself, a method which, he related, was communicated to him in a vision by the spirit of a deceased brother. Their text, with its illustrative designs and decorative marginal enrichments, was inscribed upon copper-plates with a kind of stopping-out varnish, and the surrounding metal was then bitten away with acid, the result in each case being a plate in relief, which was printed on paper with ink of various tints, the impressions being finally coloured with extreme beauty and elaboration by the artist's own hand. His innumerable designs of poetic and imaginative figure-subjects were usually executed in washed monochrome or in water-colours. They include a superb series of 537 coloured illustrations to Young's *Night Thoughts*, of which 43 subjects were engraved by Blake and published in 1797, and 12 designs to Blair's *Grave*, which were etched by Schiavonetti and published in 1808. In his paintings Blake used a method which he was accustomed to style 'fresco'—in reality a process of tempera upon a ground prepared with glue and whiting. Among the most important of such works is 'The Canterbury Pilgrims,' purchased by Sir William Stirling-Maxwell of Keir, Perthshire, which the artist himself engraved, a picture quaint in conception, and showing the errors and exaggerations of form common in the artist's productions, but full of character and individuality; 'The Spiritual Form of Pitt guiding Behemoth,' now in the National Gallery, London; 'Jacob's Dream,' shown in the Royal Academy of 1808; and 'The Last Judgment,' one of his latest paintings, executed for the Countess of Egremont. It is, however, in his engravings from his own designs that Blake's finest artistic work is to be found; and among these the 21 'Illustrations to the Book of Job' hold the first place. They were the production of the artist's old age, published in 1826, when he was verging upon seventy. In imaginative force and visionary power they are unequalled in modern religious art and unsurpassed in the art of the past, while the directness and spirit of their method recalls the works of Dürer and the other great painter-engravers of the 15th and 16th centuries. They were followed by the illustrations to Dante, upon which Blake was employed at the time of his death. He is also known as a wood-engraver by his series of 17 cuts contributed to a now very scarce edition of Thornton's *Virgil*. Though rude in execution, these prints are full of the very spirit of idyllic poetry, and their *technique* shows a remarkable perception of the true direction and special capabilities of the special artistic method.

During his life Blake met with little encouragement from the public. The exhibition of his works, which he held in 1809 in Broad Street, was a complete failure; his name was unknown to ordinary picture-buyers, and even at the end of his life, when he was producing his immortal 'Illustrations to the Book of Job,' he occupied, with his ever-faithful wife, a single small room in Fountain's Court, Strand. Yet he had his own little circle of true-hearted friends. The poet Hayley rendered him not ineffectual aid; Flaxman was his friend from youth; among his disciples in age were Samuel Palmer and John Linnell, who relieved his last days from pecuniary anxiety. All through his life he was upheld by vivid faith in the unseen, guided, as he believed, by perpetual visitations from the spiritual world. He died 12th August 1827.

A lost series of 114 drawings in sepia or ink, coloured in wash, illustrating Gray's poems, came to light in 1919 in Hamilton Palace (reprod. 1922). See editions of the works by Ellis and Yeats (1893) and G. Keynes (3 vols. 1925), of the poems by Gilchrist (1880) and by Sampson (1905; 1921); Swinburne's essay (new ed. 1906); Keynes's

bibliography (1921); books by Berger (1907), Symons (1907), De Selincourt (1909), Chesterton (1911), Nicoll (1922), Sloss and Wallis (1926), and, for his work in art, by Binyon (1906), Russell (1912), and Darrell Figgis (1925).

Blanc, MONT. See MONT BLANC.

Blanc, JEAN JOSEPH LOUIS, was born 29th October 1811, at Madrid, where his father was inspector-general of finance under King Joseph. After finishing his studies in Paris, he was for two years a private tutor at Arras, and in 1834 returned to Paris, where he contributed to various political papers. In 1839 he founded the *Revue du Progrès*, in which he first brought out his chief work on Socialism, the *Organisation du Travail*, which appeared separately in 1840. The book obtained for its author a wide, enthusiastic popularity among the French workmen, who were captivated by the brilliancy of the writing, the simplicity of the scheme, and the freshness of the views advocated. The book denounces the principle of competitive industry, and proposes the establishment of social workshops (*ateliers sociaux*), composed of workmen of good character, and subsidised by the state. These workshops, conducted on the co-operative principle, and on the basis of an equitable remuneration for all engaged in them, would, he thought, in the process of time absorb all the industry of France. Next, in 1841–44, Blanc published an historical work, entitled *Histoire de Dix Ans* (1830–40), which produced a deadly effect on the Orleans dynasty. Louis-Philippe afterwards declared that 'it acted like a battering-ram against the bulwarks of loyalty in France.' It owed its success partly to the exposure it made of the scandalous jobbery and immorality of the crown and its advisers, partly to that passionate ardour which changed the tranquillity of history into the vehemence of a pamphlet. This was followed by the first volume of a *Histoire de la Révolution Française*, in which the author's aim was to describe from his own point of view not only the incidents of the first revolution, but the social history of the 18th century. On the breaking out of the revolution of February 1848, Blanc had an opportunity of playing a most important part. His great popularity with the working-classes led to his being appointed a member of the Provisional Government, and he was placed at the head of the great commission for discussing the problem of labour, which had its sittings in the palace of the Luxembourg. At the same time, Marie, Minister of Public Works, began to establish the so-called national workshops (see ATELIERS NATIONAUX), which, however, were in no sense an attempt to carry out the views of Blanc. Blanc was accused without reason of a share in the disturbances of the summer of 1848, and escaped to London, where he spent many years. During his exile, he devoted himself to political and historical literature. He finished his *Histoire de la Révolution Française*, and carried on a large correspondence for the French journals, a selection from which was published in the bright and charming *Lettres sur l'Angleterre*. On the fall of the Empire, Blanc returned to France, and was elected to the National Assembly in 1871. After 1876 he was member of the Chamber of Deputies. In both these bodies he voted and acted with the extreme Left, but without exercising any great influence on the course of events. He died at Cannes, 6th December 1882. Louis Blanc was a man of genial and amiable personality, and a sincere believer in the most advanced political and social opinions, which he advocated with polished and fervid eloquence, but he was not robust enough to be a revolutionary leader.

Blanch, or **BLENCH HOLDING**, is one of the ancient feudal tenures in the law of Scotland without service or prestation, except as a mere badge of superiority, the duty payable to the superior being in general a trifling sum, as a penny Scots, or merely illusory, as a peppercorn, 'if asked only,' or a bunch of roses, or, as in the famous case of Jock Howieson, a service of ever and basin that the king may wash. Anciently, many estates in Scotland were held, both of the crown and other superiors, by this tenure, and by the legislation which followed on the Rebellion of 1745 all the ward-holdings or military tenures in Scotland were converted into blench; but it is now seldom adopted in the constitution of an original right of property. The tenure is subject to the same casualties of non-entry and relief as that of Feu (q.v.). See **CHARTER, TENURE**.

Blanchard, **EDWARD LAMAN**, journalist and theatrical writer, a son of William Blanchard, the comedian, was born in London, 11th December 1820, and early in life showed great aptitude for journalistic work and compilation for the publishers. Long a member of the *Daily Telegraph* staff, he wrote over a hundred pieces for the theatres, including many Christmas extravaganzas; he also published two novels. He died 4th September 1889. See *Life* by Clement Scott and Howard (1891).

Blanchard, **LAMAN**, born at Yarmouth, 15th May 1804, became a journalist in London in 1831, and died 15th February 1845. He was a popular writer of light literature. His prose essays were collected in 1846 as *Sketches of Life*, and his poetry in 1876.

Blanching, or **ETIOLATION**, is a process of culture resorted to by gardeners, to prevent certain secretions which, in ordinary circumstances, take place in the leaves of plants, and to render them more pleasant and wholesome for food. The action of light is indispensable to the decomposition of carbonic acid by the leaves of plants, and, consequently, to the elaboration of many of the substances from which they derive their peculiar qualities; the exclusion of light, therefore, renders them white or nearly so, and deprives them of much of their natural coarseness and bitterness. In cabbage and some other cultivated plants, the leaves of which form themselves into compact heads, there is a process of natural blanching. Artificial blanching is managed (1) by earthing up the leaves and succulent stems of plants, such as celery, asparagus, &c. For this purpose celery is planted in trenches, and earth is gradually drawn in round the stems as they advance in growth. (2) By tying together the leaves with strings of matting, as is sometimes done with lettuce, endive, &c. (3) By overlaying, which can be done with tiles, slates, pieces of board, or utensils made for the purpose. The most common is the blanching-pot, used to exclude the light from sea-kale, rhubarb, and some other culinary vegetables, in which the green colour is to be avoided. The common blanching-pot is of earthenware, in a sugar-loaf form, which is used in France for blanching lettuce, and in the Pyrenees for blanching celery, &c. Though so simple and easy, blanching is of great importance in gardening. Without it such a plant as sea-kale is uneatable if not poisonous; with it the common dandelion has become a wholesome and even medicinal article of salad.

Blanc-mange (Old Fr. *blanc-manger*, 'white food'), a dish formerly made of fowl, meat, eggs, &c.; now of gelatine or isinglass and milk, or of corn-flour and milk.

Blanco, **CAPE**, a remarkable headland on the west coast of Africa, in 20° 47' N. lat., and 16°

58' W. long., the extremity of a rocky ridge which projects W. and S., and forms a commodious harbour. Other headlands of the same name occur in Spain, Greece, Morocco, Oregon, Costa Rica, Peru, and the Philippines.

Bland, in Orkney and Shetland, a subacid beverage made out of the serous part of milk, of hot whey, or buttermilk and water.

Bland Act. See **BIMETALLISM**.

Blandford, a town in Dorsetshire, on the right bank of the Stour, 10 miles NW. of Wimborne. It lies in a fine tract of pasture-land, famed for its multitude of cows. It suffered much in 1579, 1677, 1713, and 1731, from fire, only twenty-six houses escaping on the last occasion. It is built of brick, and is neat and regular; its chief charm is Bryanston Park, Lord Portman's seat. It was formerly famed for its manufactures of bandstrings and lace, the point-lace bringing £30 a yard. Shirt-buttons are made here. Population (which has decreased since 1890), 3200.

Blandrata, **GIORGIO**, properly **BIANDRATA**, the founder of Unitarianism in Poland and Transylvania, was born of a noble family at Saluzzo, in Piedmont, about 1515. The freedom of his religious opinions compelled him to flee to Geneva in 1556, where he remained till Calvin's displeasure at his anti-trinitarianism drove him to Poland for liberty of thought and speech. Finally, in 1563, he betook himself to the court of John Sigismund, Prince of Transylvania, whose favourite physician he became. Here he exerted himself with as much prudence as assiduity to spread his doctrines, and succeeded in forming a considerable party. He died about 1590, strangled, so it was said, by his nephew, as he slept.

Blane, **SIR GILBERT**, physician, was born at Blane-feld, Ayrshire, in 1749. He studied at Edinburgh University, and in 1779 sailed with Lord Rodney to the West Indies, where his gallantry under fire gained him the appointment of physician to the fleet. In 1783 he was elected physician to St Thomas's Hospital, London. As head of the Navy Medical Board, he was instrumental in introducing the use of lemon-juice and other measures for the prevention or remedy of diseases on board ship. In 1812 he had a baronetcy conferred upon him. He died June 26, 1834. He published several works.

Blank Bonds. See **BONDS**.

Blankenberghe, a village on the coast of West Flanders, 9 miles N. of Bruges by rail and canal, with a harbour and lighthouse. There are fisheries and shipbuilding, and the place is a popular summer-resort. Pop. 7000 (in summer 60,000).

Blankenburg, a town and summer-resort of Brunswick, 37 miles SSE. of the capital, on the borders of the Harz Mountains. Pop. 11,500, many of them miners.—There is another Blankenburg, a favourite bathing-place with 3000 inhabitants, in Thuringia, 25 miles S. by W. of Weimar.

Blankenese, a town of Holstein, on the Elbe, 6 miles W. of Altona, a resort and residence of Hamburg people; pop. 6000.

Blanket (O. Fr. *blankete*, from *blanc*, white), originally a kind of undyed woollen cloth; now a large sheet of woollen (or other) material used as a covering for a bed, a horse, or an Indian.

The best qualities of blankets made in England are wholly of wool, but what may be called a typical English blanket of medium or inferior quality is generally formed of cotton warp and woollen weft threads, since, owing to the peculiar way much of the wool is spread in an open pile over the surface of the fabric, the cotton gives it strength. One of the chief aims of the manufacturer is to

raise the fibres of the woollen yarn into a loose, soft mat on the face of this kind of blanket, which hides the threads below. This is effected by Teazles (q.v.), or steel brushes, in what are called gigs or brushing-machines. Scotch blankets, even of ordinary quality, on the other hand, are entirely made of wool, and are finished in a different way, the pile on the surface not being sufficient to hide the twilled pattern into which they are woven. An imitation of the Scotch blanket is made in some mills at Sowerby-Bridge in Yorkshire. Cloth or Bury blankets, again, have a surface more like ordinary woollen cloth. Witney, Kersey, Yorkshire, and Bath are the best-known varieties of English blankets. Dewsbury is the principal centre of the trade. The Scotch blanket-mills are chiefly situated in Ayrshire, Berwickshire, and at Markinch in Fife. Some blankets made in Ayrshire are not of the ordinary Scotch type. The 'Witney' and 'Bath' are perhaps the most comfortable blankets made in Great Britain, but none of the English kinds can compare with the Scotch blanket for economy. The latter is by far the most durable.

The more expensive kinds of American blankets excel in weight, thickness, softness, and perfection of face. The lowest grades, composed of shoddy, hair, and the coarsest wool, which are saleable abroad, cannot be disposed of in America—even the Indians will not have them. Extraordinarily fine woollen blankets are made in Mysore; some, it is said, so delicate that, though as much as 18 feet long, they can be rolled inside a hollow bamboo.

Blanketeers, a body of Manchester operatives who on 10th March 1817 met in St Peter's Field, provided each with a blanket for bivouacking. They meant to join a contingent from Derby, and march on London; but they were dispersed.

Blanks, SPANISH, certain papers, blank but for the signatures of Errol, Huntly, and others, intended to be filled up with an agreement to help a Spanish invasion of Scotland (1592). The papers were intercepted, and Errol and his friends raised a rebellion, and afterwards withdrew from Scotland.

Blank Verse, or verse without rhyme, a name applied especially to the iambic pentameter or unrhymed five-foot iambic, the so-called heroic verse, the regular measure of English dramatic and epic poetry. The first specimen of blank verse in English is a translation of the second and fourth books of Virgil's *Æneid*, by the Earl of Surrey (beheaded in 1547); but it had been used freely by Italian and Spanish writers as early as about the beginning of that century. The first example of an English poem of any length (not dramatic) in blank verse is *The Steele Glas* (1576) of Gascoigne. Two short poems of Nicholas Grimald, published in *Tottel's Miscellany* in 1557, are the earliest specimens in English of original blank verse. In England the adaptation of this verse to the drama (first in Sackville's *Gorboduc*, from the freedom gained by the variations of the pause, was at once felt, and in that department of poetry it soon became and has continued dominant, if we except the effort made by Dryden and others, after the Restoration, to return to rhymed plays. For dramatic purposes the four-accent line is too short, and breaks the sense too often, while the six-accent line is so long as to be tedious without the relief of rhyme. The five-accent verse was a satisfactory mean between the two. The dramatic line, representing the language of actual life, approaches more nearly to prose, and consequently enjoys more license than any other metre. Not merely is the trochee freely substituted for the iambus after any pause however slight, but an extra syllable is also allowed at the end of a line or sentence (even in Milton), and in some cases even two extra

syllables, if these do not interfere with the regular recurrence of the accent.

Of course in verses of five accents it is impossible to divide the line into two *equal* parts, so that there must needs be variation in the position of the pause to avoid what would otherwise be unendurable monotony. In verse without rhyme much of the beauty of the rhythm depends on the poet's skilfulness in the variation of the pause, and no one has varied it with more boldness and finer effect than Milton. Professor Mayor points out that 'Tennyson and Browning, as compared with Milton, have more lines with final, but without internal pause; somewhat fewer with internal, but without final pause; about the same without any pause at all. As to the forbidden internal pauses, they use the pause after the first, third, and ninth syllables more frequently than Milton, and do not differ much from him in their use of the pause after one and a half, two, and eight. With regard to the middle pauses, those which divide the feet, coming after the fifth or seventh syllable, are more favoured by the moderns than by Milton, whose commonest pause is after the sixth syllable, and then *longo intervallo* after the fourth. The pause after the fourth seems to be Tennyson's favourite, while Browning seems to prefer the fifth and seventh. This last also abounds in Swinburne. Feminine ending is very rare in Browning, but in Tennyson is hardly less frequent than in Milton. Nor is there any marked difference as regards substitution of feet, except that the non-initial trochee is more common in Milton than in the others.' The initial trochee is as common in Surrey as in Milton. The rhythm of the former is frequently harsh and abrupt. Trisyllabic feet are not infrequent, and as often as not there is no middle pause. Marlowe's rhythm is much more regular in accentuation than Surrey's, but occasionally we find monosyllabic feet and lines of nine syllables formed by initial truncation. Feminine rhythm is also more frequent than in Surrey's usage, and even the two superfluous syllables at the end of the line occur here also. Many of Shakespeare's defective lines are capable of explanation by a pause or a lengthened syllable. Examples of elision and slurring are frequent, and trisyllabic feet are not uncommon, but genuine Alexandrines are not numerous. The superfluous syllable at the end is rare in his earlier plays, but there is a steady increase in its use in the later plays. It is but rarely a monosyllable, still more rarely an emphatic monosyllable. Such amphibrachic or 'double endings' are especially common in Fletcher's verse.

Dryden followed Corneille in demanding rhyme for the dignity of tragedy. He sums up its advantages in aid to the memory, in additional grace added by the sweetness of rhyme to the smartness of a repartee, and in the limits that it lays upon the fancy, which without such restraint tends to outrun judgment. Milton's *Paradise Lost* (1667) was the first great poem in our literature written in blank verse. Appended at the publisher's request was a short preface in three sentences, entitled 'The Verse.' Here the poet, with customary vigour of phrase, claims exemption from 'the troublesome and modern bondage of riming . . . to all judicious ears, trivial and of no true musical delight . . . no necessary adjunct or true ornament of poem or good verse, in longer works especially, but the invention of a barbarous age, to set off wretched matter and lame metre.' From Milton's time blank verse has been as common a form for narrative, didactic, or descriptive poetry, as rhymed couplets with their 'jingling sound of like endings.' Some would restrict the name blank verse to the ordinary heroic metre or lines of ten syllables; by others the

term is applied more widely to unrhymed lines, irrespective of their length, from such examples as the *Hiuvatha* of Longfellow, which contains eight syllables in its lines, to his *Evangeline*, which has as many as sixteen or even more.

The five-foot iambic appears early in both Italian and French, but in neither did it shake off the bondage of rhyme, as it did in England by the middle of the 16th century, so as to offer a sufficiently strong and flexible form for dramatic and epic poetry. French influences long exercised a restraining effect on its use in German, but English freedom made its way through the efforts of the elder Schlegel, Wieland, Klopstock, Herder, and others, until Lessing employed the unrhymed five-foot iambic in his *Nathan* in 1778, and thus set a precedent for its use in dramatic poetry. In earlier German verse in this measure as in French, each five-foot line was complete in itself, but Lessing introduced the usage of the Italians, and still more the English, of connecting lines by *enjambement* and building them up into long periods. Schiller's first plays were written in prose, but in 1786 he began to employ the five-foot iambic as modified by Lessing.

See J. B. Mayor's *Chapters on English Metre* (1886), with its summary of an essay by Zarncke (1865); and works by Guest, Bridges, Symonds, Schipper, and Saintsbury.

Blanqui, JÉRÔME ADOLPHE, a French economist, was born in 1798 at Nice, and commenced the study of philology at Paris, where he became acquainted with J. B. Say, who induced him to turn his attention to political economy. In 1833, on the death of Say, he was appointed professor of Industrial Economy in the Conservatoire des Arts et Métiers, and became one of the editors of the *Dictionnaire de l'Industrie*. In 1838 he became a member of the Academy of Moral and Political Sciences. Later he travelled in several countries to study their economic condition. He died at Paris, 28th January 1854. As an economist, he was a follower of Say, and in favour of free-trade, and he recognised the social difficulties of his time. In method he is ingenious, in style transparent and lively. His most important work is the *Histoire de l'Économie Politique en Europe* (1838).—His brother, LOUIS AUGUSTE BLANQUI, born at Puget-Théniers (Alpes Maritimes) in 1805, made himself conspicuous by his passionate advocacy of the most extreme opinions, for which he suffered with the pride of a martyr. He was one of the foremost fighters in all the French revolutions of that century. In 1830 he was decorated for his valour at the barricades. In 1848 he figured as the chief organiser of the popular movement under the Provisional Government. He took the lead also in the revolutionary *attentat* of the 15th May, the aim of which was to overthrow the Constituent Assembly. At the head of an excited mob, he demanded of the French representatives the resuscitation of the Polish nationality, while one of his friends pronounced the dissolution of the assembly. For his share in these disturbances he was rewarded with ten years' imprisonment in Belleisle. In 1861 Blanqui was sentenced to other four years' imprisonment. After the downfall of the second empire in 1870, Blanqui resumed his revolutionary activity, and in 1871 took a prominent part in forming the Commune. Being too unwell to endure transportation in New Caledonia, he was condemned to imprisonment for life, from which he was released in 1879. He died January 1, 1881, having spent nearly half his life in prison.

Blantyre, or HIGH BLANTYRE, a village of Lanarkshire, situated near the right bank of the Rotten Calder, 8½ miles S.E. of Glasgow by rail, in a coal and iron mining district. At the now decay-

ing village of Low Blantyre, 1½ miles N.E., David Livingstone, a native, worked in a weaving-factory; here also are his memorial church and statue.—Also a Scottish mission-station founded in 1876 in Nyasaland, on the heights between the Upper Shire and Lake Shirwa, in a well-wooded district.

Blaps, a genus of Black Beetles (q.v.), with more than 100 species. They are dark and darkness-loving forms, wingless, leisurely in their movements, feeding on dead vegetable matter, and with the power of ejecting for several inches an acrid fluid of pungent odour. *Blaps mortisaga* is a common British species, of about an inch long, and of a shining black colour. It is sometimes called Darkling Beetle, and Churchyard Beetle, and sometimes seems to share with the Cockroach (q.v.) the appellation of Black Beetle. It is a frequent companion of the cockroach in pantries and cellars, and used to be thought a messenger of death, but is rather frequent for such an ominous function.—*Blaps sulcata* is cooked with butter and eaten by Turkish women to make them fat.

Blaps.

Blarney is the name of a castle 8 miles N.W. of Cork, in the outer wall of which, 20 feet from the top and so quite inaccessible to ordinary visitors, is a stone bearing the date 1446, said to endure any one who kisses it with heroic powers of cajoleiy.

Blasco Ibáñez, VICENTE, Spanish novelist, born at Valencia in 1867, deals in realistic fashion with provincial life and social revolution. Notable among his novels are *La Catedral* (trans. 1909), *Sangre y Arena* (trans. 1913), *Los Cuatro Jinetes del Apocalipsis*, and *La Barraca*. The two last mentioned, translated in 1919, established his popularity with English readers. He has been found fault with for bad taste and provincialisms; but Mr W. D. Howells reckoned him the greatest of living novelists since the death of Tolstoi.

Blasius, St, Bishop of Sebaste, Cappadocia, suffered martyrdom in 316. His relics are abundant. The wool-combers claim him as patron, because iron combs were used to tear his flesh. He was also invoked in extracting a thorn or anything sticking in the throat. His day is 3d February.

Blasphemy, according to the canon law, was either heretical or simple. The former consisted in denying God or an article of faith, and this was regarded as injuring the reputation of the Deity, and shocking the mysteries of religion. Simple blasphemy, on the other hand, consisted in making untrue and unbecoming statements about God, the Virgin, or the saints. These offences were severely punished both at Rome and in the Cismontane churches, though not with the capital penalty which was usual against blasphemers under the Jewish law. In England the law is partly statutory. A statute of 1698, repealed in 1813 so far as it protected the doctrine of the Trinity, declares it to be an offence 'to assert that there are more gods than one, to deny the Christian religion to be true, or the Holy Scriptures of the Old and New Testaments to be of divine authority.' The punishment is incapacity to hold office, and on a second conviction imprisonment for three years. Under this statute such writers as Matthew Arnold, F. W. Newman, and J. S. Mill could undoubtedly

have been convicted, serious and high-minded as are their books. But the prosecutions for blasphemy in England have been under the common law, and there is a difference of opinion among the highest authorities whether the simple reverent statement of certain opinions amounts to blasphemy, or whether a scoffing and contumelious spirit is not necessary to complete the offence. The older cases, such as that of Woolston who in 1728 attacked the Christian miracles, Williams who published Paine's *Age of Reason* in 1797, Carlile in 1819, and Moxon who sold Shelley's *Queen Mab*, tend to show that, as Lord Kenyon said, 'the Christian religion is part of the law of the land,' and therefore that to question its truth, however seriously, is an offence. The theory of such convictions is much weakened by the legislation permitting jurors and witnesses to avoid the oath, for it was thought that the theological sanction of Christianity was necessary for the due administration of justice. But the case of Cowan, who in 1867 proposed to lecture on 'the character and teachings of Christ; the former defective, the latter misleading,' confirms the view that blasphemy depends on the character of the matter published, not the manner in which it is stated. The opposite doctrine, however, was laid down by Lord Coleridge in the case of Foote and Ramsay in 1883, and is now generally accepted. The complete toleration of religious opinion which now exists renders it improbable that any one will be prosecuted for a decent expression of disbelief in Christianity. But the point is not beyond doubt, for so great an authority as Mr Justice Stephens favours the view expressed in Cowan's case, though he admits that there is 'some authority in favour of a different view of the law.' It may be pointed out that, as in the case of Page Hopps at Glasgow in 1874, Unitarian books are held not to be blasphemous at common law, and to be therefore entitled to copyright. This would seem to imply that the principle laid down in Foote's case is right. In Scotland there is also a statute law and a common law of blasphemy. Under the Act of 1661 (repealed in 1813) the punishment was death, but the acts now in force are those of 1825 and 1837, under which blasphemy may be visited with fine or imprisonment, or both. It was under the early régime that the atrocious judicial murder of Aikenhead, with the approval of the ministers of Edinburgh, was perpetrated in 1697. As in the case of the Edinburgh booksellers, Paterson and Robinson, in 1843, it is a crime at common law to publish an impious book devised to ridicule or bring into contempt the Scriptures or the Christian religion. The accused in these cases were sentenced to fifteen and twelve months' imprisonment. Holyoake was imprisoned six months at Gloucester for 'bringing God into disbelief.' The courts of the United States also hold that one who maliciously uses language calculated to sap the foundations of society and public order may be punished; but evil motive is essential to the offence, and discussion of religious doctrine is not to be interfered with.

Blast-furnace. See BLOWING-MACHINES, IRON AND STEEL.

Blasting is the method of loosening or shattering masses of solid fracturable matter by means of explosive compounds, an operation of fundamental importance in engineering and mining. Previous to the invention of gunpowder the only means of quarrying stone and of extracting minerals from the earth was by the hammer, chisel, and wedge, or by the expansive power of heat. For obtaining large regular blocks of stone the wedge is still often used, and blasting has to do not quite so much with quarrying as with mining of all kinds, with disintegrating rock in the sinking of shafts, the

cutting of tunnels, the formation of roads and railways, the removal of obstructions to navigation, and generally the shattering or displacement of solid masses. While there are indications of the use of gunpowder for military mining in the 15th century, the first record of its employment for ordinary blasting is 1627, at a mine near Schemnitz.

The explosives commonly used in blasting consist of gunpowder and preparations of nitro-glycerine, nitro-cotton, or gun-cotton, and of several nitrates and nitro-compounds. Nitro-glycerine (q.v.) is now never used in the free condition in Great Britain, and abroad probably used only in exceptional circumstances. As Dynamite (q.v.), and in a great number of other blasting explosives, it is absorbed and retained by various ingredients with comparative safety, but somewhat (often adversely) diminished blasting efficiency. Ammonium nitrate is the base of a number of other, generally less powerful, blasting explosives specially designed for use in coal-mines where danger of explosion from 'fire-damp' or coal-dust may exist. Numerous other explosives have been proposed and introduced; but many of them, from their instability, or from the great risks of their manufacture and handling, are prohibited under the provisions of the Explosives Act. To meet the objection to explosives in confined spaces and in 'fiery' mines (as they give off a certain amount of poisonous gas when fired), the expansion of quicklime when wetted, compressed air, and wedge-machines have been used for splitting rock and coal. The first mentioned has been dropped, but the two latter are still used in certain special circumstances, though useless for hard strata or for rapid work.

The use of modern explosives renders three kinds of blasting practicable—(1) the small-shot system, (2) the mine system, and (3) surface blasts. The small-shot system consists in boring holes, 1 inch to 1½ inch diameter, sometimes more, and from 18 inches to 6 or 7 feet into the material to be blasted. The boring is done either by hand or machine power (see BORING). The hole is cleaned out, and the charge, generally in the form of a cartridge of sufficient diameter for the bore, is placed in its extreme end, and the remainder of the hole is tamped or closed with sand or clay. If the cartridge be filled with an explosive such as gunpowder, which only requires simple ignition to explode it

Section of a Tunnel.

with full effect, a Fuse (q.v.), such as Bickford's, passes through the tamping to the cartridge; but if the explosive be one which requires detonation to develop its complete force, the fuse is attached to a *detonator* (a small metal tube containing from twelve to thirty grams of fulminate of mercury) embedded in the cartridge. The fuse is cut to a length which will burn for a sufficient time to enable the workmen to get clear of the effects of the explosion. Firing by electric fuse

from a distance is, however, increasingly employed, especially when a number of shots have to be fired simultaneously, for in the latter case the difficulty of getting burning fuses to act at the same moment is considerable. 'Cordeau détonant,' i.e. a high explosive, such as trinitrotoluene, in a lead tube, is a new means of bringing about simultaneous firing. One tube connects all the charges, and the enormous velocity of detonation (about 18,000 feet per second) of the tube brings about a result practically equal to that obtained by electric firing, and less liable to derangement. In tunnelling and shaft-sinking, a series of shot-holes which embrace the superficial area to be excavated are driven and exploded in a connected manner, a core or central set being first fired off, after which a ring of shots around the core are simultaneously fired, and so on till the whole area is embraced.

The system of shot-holes is very similar for all forms of blasting, but the explosive used is carefully selected according as it is desirable or not that the material blasted shall be broken into small

3 inches—in all, more than 20 miles of drill-holes. Into each of these was inserted, first, a cartridge of rackarock—79 parts chlorate of potash and 21 dinitrobenzole; and, second, a cartridge of dynamite, the two together filling the entire bore. In all, there were used 240,399 lb. of rackarock and 42,331 lb. of dynamite. Water was admitted to the mine, and it was exploded on the 10th October 1885. Over 80,000 cubic yards of rock were tunnelled out, and 270,700 cubic yards were blasted.

Surface blasts are explosions produced by firing the explosive simply in contact with or placed near the substance to be shattered. Such blasts have become possible only since the introduction of detonating explosives. Gunpowder fired in an unconfined space would spend its force through the air, and produce little local effect; but the detonation of nitroglycerine, gun-cotton, and other nitro-compounds is so sudden that it acts with enormous violence in every direction, though within a limited area. Thus blasts of detonating compounds laid on the surface of any rock, &c., and fired by a detonator.

operate downwards and produce great shattering effects (see Detonation under GUN-COTTON). Surface blasts have been largely used in removing reefs and other obstructions to navigation in the Long Island Channel, New York, the scene of the greatest of blasting operations.

In recent years, especially in America and Canada, blasting has been much employed for clearing old forest land of the

Section Diagram of Hell Gate Tunnels.

pieces. For such a material as coal a comparatively gentle explosive would be employed; whereas for blasting out hard rock, the debris of which is to be used as road-metal, the most powerful explosive available would probably be used.

Large blasts or mines are resorted to when great masses of rock have to be removed at once, or when a large supply of irregularly broken stone is required. These blasts are of two kinds—shafts sunk from the top of the rock, and headings or galleries driven in from the face. In a shaft mine the charge of powder is placed in a chamber cut at one side of the shaft, so that the tamping may not be in the direct up-line of fire. It is exploded by electricity, the wires from the battery being protected from injury from the rough tamping by being embedded in battens placed up one side of the shaft. Headings are driven, if possible, along a natural joint in the rock. The explosive may be divided and placed in two or more separate chambers, and it is better to distribute large charges than to fire them at one centre. The charges in these mines vary from 600 lb. to 13,000 lb. of powder, and even more, and they should dislodge from 3 to 6 tons of stone per lb. of powder exploded. The Round-down Cliff at Dover was in 1843 overthrown by a blast of 18,500 lb. of powder in three separate charges. An enormous blast was made in slate-quarries near Llanberis in October 1893, when some 235,000 tons of granite were displaced by 6850 lb. of blasting gelatine (see GUN-COTTON). The removal of Hell Gate or Flood Island, in Long Island Sound, New York, required the greatest blast the world had seen. The island, 9 acres in extent, was honeycombed under low-water mark with tunnels—24 galleries running in one direction, intersected by 46 at right angles. These galleries were pierced in every direction with drill-holes, of which there were bored 12,561, with a depth of 9 feet and a diameter of

stumps of trees, and even for breaking up soil to an extent which would be impossible with the most powerful ploughs.

Blastoderm, the layer or layers of cells arising from the germinal disc, or the portion of a partially segmenting egg which undergoes division; see EMBRYOLOGY.

Blastoids. See ECHINODERMATA.

Blastophaga. See CAPRIFICATION.

Blatchford, ROBERT, born at Maidstone in 1851 of actor parents, was bred a brushmaker, and served in the army and as a clerk. After being on the staff of *Bell's Life* and the *Sunday Chronicle*, he founded and edited the *Clarion* in the interests of socialism and free thought. Among his works are *Merrie England*, *Tommy Atkins*, *A Son of the Forge*, *A Bohemian Girl*, *God and my Neighbour*, *Not Guilty*, *Sorcery Shop*.

Blauwbok, a large South African antelope, now extinct; see ANTELOPES.

Blavatsky, MADAME. See THEOSOPHY.

Blaydon, a manufacturing town of Durham, 5 miles W. by S. of Newcastle; pop. 33,000.

Blaye, a river-port on the Gironde, 20 miles NNW. of Bordeaux, at the base of an eminence crowned with Vauban's citadel (1652); pop. 5000.

Blaze de Bury, HENRI (1813-88), born at Avignon, translated *Faust* and wrote on Goethe and the German poets, on society under Augustus, and on the great musicians.—His wife (1814-94), named Stewart, born at Oban, and bred in France, wrote much both in French and English.

Bleaching (A.S. *blæcan*, from *blæc*, *blac*, 'pale,' 'bleak') is the whitening of textile materials or fabrics by the removal of coloured substances natu-

rally present or adhering to them in the course of their manufacture. It is also used to signify the decolourising of beeswax, castor-oil, and similar fatty materials by exposure to sunlight, sometimes in presence of water. From time immemorial open-air bleaching, with sun exposure, has been applied to linen and cotton fabrics, and is still for the most part the method adopted for domestic purposes. The strong bleaching power of direct sunlight is strikingly seen in the case of a wax or paraffin candle coloured with some of the aniline or vegetable dyes, an hour or two sometimes sufficing to discharge the colour. In diffuse daylight they also bleach, but much more slowly. Many dyes on textile fabrics, as is well known, soon fade if much exposed to the sun's rays.

It was formerly the custom to send linen goods manufactured in Scotland to be bleached in Holland, and the name *Holland* is still retained for a kind of unbleached linen. Another variety, which, from its fineness, was generally spread on the better grass-fields or lawns, received the name of *lawn*, still in use for a fine white linen. In those days large areas of grass land, and several months' exposure to air, light, and moisture, were required to bleach linen white. The first bleachfield in Scotland was established by the Fletchers at Salton in East Lothian about 1730; others were started soon after at Ormiston and Perth. Near Perth, and in Fife, there is still a good deal of open-air bleaching combined with chemical treatment. Bleach-works were also early set agoing about Glasgow and Aberdeen.

Andrew Yarranton, writing in 1677, mentions that a bleachfield then existed in Southwark by the side of the Thames, but there does not appear to be much known about early bleachfields in England.

In the old Dutch process the linen was immersed for some days in an alkaline lye of crude potashes, which removed a large quantity of the natural colouring matter and stains. It was afterwards treated with sour milk before it was spread on the grass. The process, including the field bleaching, took from six to eight months. Dr Home of Edinburgh discovered about 1756 that dilute sulphuric acid did better for the 'souring' operation than sour-milk, an improvement which shortened the time occupied in bleaching by one-half.

The modern process of bleaching calico, linen, and other fabrics of vegetable fibre, may be said to date from 1785, when Berthollet read to the French Academy an account of his investigations on the power of Chlorine (q. v.) to destroy colouring matters. A knowledge of the use of chlorine as a bleaching agent appears to have been first brought to this country by the Duke of Gordon and Professor Copland of Aberdeen, who communicated it to a firm of bleachers in that town. James Watt, who knew Berthollet, made the process successful at a bleachfield near Glasgow, and along with Dr Henry of Manchester, explained it to the Lancashire manufacturers of cotton cloth, a branch of industry then rapidly rising in importance. Mr Charles Tennant of Glasgow took out, in 1798, a patent for making a solution of the chloride of lime, and afterwards in 1799 made this substance in the solid state by exposing dry slaked lime to chlorine gas, which it readily absorbs in large quantity. This was a discovery of great importance. Under the name of *Bleaching Powder* this solid chloride of lime continues to be the chief material used as a bleaching agent. This substance is commonly called chloride of lime, but as explained under BLEACHING POWDER its exact nature is still uncertain.

Bleaching of Cotton.—The cotton fibre as removed from the seed consists essentially of cellulose, but also contains various impurities, which

must usually be removed to a greater or less extent in order to render the fibre suitable for dyeing, &c. These impurities consist mainly of fatty and waxy matters, pectic substances, and small quantities of mineral matter, and on the average do not exceed in amount 5 per cent. on the weight of the raw cotton. Manufactured cotton fabrics also contain a considerable amount of other impurities—e.g. starches, fats, soaps, oils, &c.—which are added to assist the manufacturing operations.

The principles underlying the usual bleaching process are as follows: (1) the removal of the fatty, waxy, and pectic matters by means of alkalis; (2) the removal of mineral matter by acids; (3) the destruction of the residual colour by oxidising substances. The details given below refer to the bleaching of cotton-cloth or calico, which is by far the most important branch.

For convenience in handling, the pieces are usually sewn together end to end so as to make a long band of cloth. In most cases they first undergo the 'singeing' operation in order to remove the loose fluff from the surface of the cloth. This is carried out by passing the pieces very rapidly in the open width over copper cylinders or plates heated to redness, or else over a row of Bunsen-gas flames. For the remaining operations the cloth is not kept in the open condition, but the long band is allowed to twist up into a rope-like form, and is run over winches from one machine to the next in that condition.

The exact process employed varies greatly, but the following is an example of a 'full bleach,' which consists of the following operations: (1) the gray wash or steep; (2) the lime boil or bowk; (3) the lime or gray sour; (4) the lye boils; (5) the chemick; (6) the white sour. A thorough wash with water is given between each of the above operations. For the *gray wash* the pieces are steeped for some time in water to which a little malt extract or other chemical substances are sometimes added. This operation converts a portion of the starchy impurities into soluble substances by a process of fermentation, so that they can be removed by a wash with water. For the *lime boil* the pieces are impregnated with milk of lime in a 'liming-machine,' so as to take up about 4 to 5 per cent. of their weight of lime, and are then run into a 'kier' (see below) and boiled for several hours with lime-water either without, but usually with, pressure. The usual explanation of this process is that the lime decomposes the fatty and waxy impurities, forming insoluble lime-soaps, which remain adhering to the goods, but are removed by later operations. After the lime boil the cloth is well washed with water, first in the kier and afterwards in a washing-machine (see below). The *gray sour* consists in passing the washed pieces through a solution of hydrochloric or sulphuric acid of about $\frac{1}{2}$ to 1 degree Twaddle in strength. This decomposes the lime-soaps, liberating the fatty acids which remain adhering to the cloth, and removing the lime and other mineral matter in the form of soluble salts. A good wash follows. The next operation, the *lye boil*, consists in boiling the cloth in a kier with soda ash or other alkali. This is frequently carried out in two stages, the pieces being first boiled with a solution of soda ash, caustic soda, and resin-soap, and then with soda ash alone, followed by the usual good wash. This operation removes the fatty acids and other impurities, and leaves the goods almost white except for a slight yellowish tinge, which is removed by the next operation—that of *chemicking*. For this the pieces are run through a very dilute solution of bleaching-powder of about $\frac{1}{2}$ to 1 degree Twaddle, left to lie for some time, and then (sometimes after washing) run through the

white sour (like the gray) to complete the decomposition of the bleaching-powder and to remove the lime, and finally well washed with water, opened out again to the full width, and dried, which completes the process.

Bowling Kiers.—The kiers employed for the lime and lye boils are of various kinds, but usually have the form of vertical iron cylinders which hold from one to five tons of cloth. In order to get satisfactory results a good circulation of the liquors used is most important. This is usually effected by steam-injectors, pumps, or vacuum arrangements, or by a combination of these. When injectors are employed they effect the heating of the liquor at the same time, but for the others a special heating installation must be provided, which usually consists of a tubular heater placed outside the kier. In some cases the boiling is done in open vessels, but much better results are obtained by boiling under pressure, and there is a considerable saving of time.

An example of a high-pressure injector kier (Sir James Farmer & Sons, Limited) is shown in the annexed diagram. It consists of a large, vertical, cylindrical vessel made of steel or other suitable metal, and holding about three tons of cloth. The pieces are packed as evenly as possible in the kier after liming, and rest on a perforated

the pressure has risen sufficiently it ejects some of the liquor out of the open top of the pipe against a baffle-plate or spreader, A, which distributes it over the top of the goods, through which it gradually sinks until the steam pressure has risen again so as to eject another lot of liquor in a similar manner to the first. By this arrangement the liquor is thrown up in an intermittent or 'vomiting' manner. This kier is fitted with a safety-valve, J, and also with an inlet-valve, C, through which steam or water can be passed into the kier as required.

Another form of kier in large use is the 'Mather kier.' In this the cloth is packed into perforated iron wagons holding about two tons each, and two of these are then run on rails into the kier, which consists of a horizontal iron cylinder or boiler. The kier is then closed, and the necessary liquids are showered over the cloth in the trucks by means of pumps. After the cloth has been washed with water in the kier the door is opened and the wagons are run out, and two more which have been already filled with cloth are run in, and the same process carried out. By this method there is a considerable saving in the time required for filling and emptying the kiers.

Of recent years the process of bleaching in the open width has found considerable favour. In

this process the pieces are passed continuously in the open width through closed rectangular vessels which are fitted with rollers to carry the cloth and have water-seals at the inlet and outlet places. In these kiers the cloth is subjected to alternate treatments with boiling alkaline liquids, and to a steaming process which takes place above the surface of the liquor in the closed kiers. The chemicking and souring follow as usual in other machines. Caustic soda and soda ash are the chief chemicals used in the Mather and open-width kiers.

Of recent years the lime boil has been much less employed than formerly, and the cotton is often simply given one or more lye boils, washed, chemicked, soured and washed. This is the process usually employed for loose cotton and yarn. For cotton which is to be dyed in dark shades a simple boiling out with soda is frequently sufficient.

Washing-machines.—For the repeated washings, the old dash-wheel is still to some extent used, and is a very efficient machine, but the operation can be got through in much less time by some more recent machines. One of these consists of a pair of squeezing rollers

with suitable framework placed over a cistern, through which there is a continuous flow of clean water. The pieces of calico, joined at the ends, pass in a rope-like form between these rollers, descend into the water, pass round a submerged roller, and return to the pressure rollers, from which they again descend to the cistern. In this way, guided by a rail with pegs, the calico travels round in a spiral direction, descending and ascending till the operation is finished.

Electric Bleaching.—Of recent years the use of sodium hypochlorite prepared by the electrolysis of solutions of common salt has attained some prominence. Omitting numerous side reactions, the main effect of passing a current of electricity through a solution of common salt is expressed by the following equations: $\text{NaCl} = \text{Na} + \text{Cl}$; $\text{Na} + \text{H}_2\text{O} = \text{NaOH} + \text{H}$; $\text{Cl}_2 + 2\text{NaOH} = \text{NaOCl} + \text{NaCl} + \text{H}_2\text{O}$; the final result being a solution

High-pressure Injector Kier.

plate placed near the bottom of the kier. The top of the pile of cloth is covered with a sheet, and prevented from rising too high in the kier during the boiling process by means of weights or chains. Water is then run in so as to cover the goods, the lid is closed, and steam is blown in to remove the air, which escapes by the air-valve, F, after which the latter is closed. The circulation is effected as follows: Steam enters by the valve B, passes down the descending-pipe, and enters the bottom of the kier in the form of a jet. This jet is placed beneath the conical end, D, of the puffer-pipe, G, which runs up the centre of the kier and projects above the surface of the liquor. The liquor in the goods sinks through the perforated plate, and enters this pipe through openings in the conical portion, and rises to a certain height in the puffer-pipe. When steam is turned on, the rush of steam up the pipe carries the liquid up with it, and when

containing sodium hypochlorite and chloride, together with smaller quantities of other substances produced by the side reactions referred to above. The solutions thus obtained have the advantage over bleaching powder solutions that they contain no lime, so that the souring process can be omitted, a simple washing with water being sufficient to remove the easily soluble soda salts. However, the plant employed in its manufacture is expensive, and unless electric-power can be obtained at a very low price the process is more expensive than the use of bleaching powder in the ordinary way.

Bleaching of Linen.—Flax fibre from which linen is made contains a much larger amount of impurities than cotton. On an average they amount to about 30 per cent., as compared with 5 per cent. in the case of cotton. The process of water-steeping or 'retting,' which is the first stage in the preparation of the fibre, also causes a darkening of the fibre. The impurities consist largely of pectic and mucilaginous bodies. The process of bleaching linen is very similar to that employed for cotton. Owing, however, to the structure of the fibre, which consists of bundles of filaments adhering together, the separation of which must be avoided as much as possible, very dilute chemical solutions must be employed; and owing to the large amount of impurities the various operations must be repeated one or more times in order to get a good bleach. One operation which is peculiar to linen-bleaching is the 'crofting' or 'grassing,' which consists in spreading the material on the fields and exposing it to the action of the weather at different stages of the bleaching process.

Bleaching of other Vegetable Fibres.—Jute can be bleached by means of bleaching powder, but it is better to use sodium hypochlorite in place of the lime compound. Jute is easily injured by chemicals, so that the solutions should be used weaker than is the custom with cotton.

Hemp, coconut fibre, and other less important vegetable fibres are usually bleached by first treating them with hot soda solutions and then with solutions of bleaching powder.

Bleaching of Paper.—Rags, esparto grass, straw, wood, jute, and other materials are used for making paper, and these are usually bleached in the state of half stuff—i.e. after they have been so far reduced in the beating-engine. White papers are largely made of esparto mixed less or more with rags. The half stuff is bleached with chloride of lime, which is subsequently washed out. Afterwards the paper material is generally treated with an 'antichlore,' consisting either of hyposulphite of soda or of hyposulphite of lime, to remove the last of the chlorine, which, if left, would rot the paper. Straw is easily bleached, but this is not the case with wood. When straw is used for making bonnets, it is bleached with sulphurous acid.

Bleaching of Wood.—Trials made in 1887 in the bleaching of wood for ornamental purposes by means of peroxide of hydrogen have proved very successful. The wood is cut up to the required thickness, which may be from one twenty-fifth to one-fifth of an inch, and immersed in a bath of this liquid kept alkaline by the occasional addition of ammonia. In a few days this thin boarding appears almost white and transparent. It dries without shrinking or losing strength. The grain and veining, it is said, lose nothing of their distinctness from being subjected to the process; only the colouring disappears.

For the bleaching action of charcoal, and especially animal charcoal, on organic colouring matters in solution—such as the watery extracts of barks for medical purposes, brown sugar, paraffin, and a few other bodies—see CHARCOAL.

Bleaching of Wool.—Animal fibres such as wool and silk cannot be bleached by the methods employed for vegetable fibres, as they are easily injured by alkaline liquids and bleaching solutions. Raw wool as it comes from the sheep is contaminated with a considerable quantity of impurities, consisting chiefly of the following: (1) fatty and waxy substances forming the 'wool fat'; (2) the wool perspiration, chiefly the potash salts of various fatty acids; (3) dirt of various kinds—earth, vegetable matter, &c.; (4) colouring matter.

The first step in the purification is the removal of the impurities of the first three classes by the operation known as 'scouring.' This usually consists of a treatment with lukewarm soap solutions to which small amounts of soda, ammonia, or other mild alkali are sometimes added. The process is carried out in a series of long, shallow, rectangular tanks which contain the scouring liquor. The wool is entered at one end and gradually moved through the liquor to the other end by means of an arrangement of automatic rakes which give it a very gentle motion. All rapid movement must be avoided, as the wool very readily felts or knots together, and so causes losses in the subsequent manufacturing operations. The wool is passed through two or more of these machines, each of which contains a cleaner soap solution than the preceding one, and is then rinsed in water and dried. The wool fat, although insoluble in water, forms an emulsion with the soap solution, and is thus removed.

There are several methods for removing the actual colour from wool, the most important being that known as 'stoving' or 'sulphuring.' The well-scoured wool is placed in a closed chamber, the fumes of burning sulphur are then passed in, and the wool left exposed to them for several hours. The reaction is $S + O_2 = SO_2$. In some cases the sulphur dioxide is applied in the form of its solution in water. The SO_2 reduces the colouring matter to colourless substances. A better but more expensive method consists in the use of hydrogen peroxide. The wool is soaked for several hours in a solution of this substance, which is gradually heated to about 120° F., then lifted and rinsed. The colour is destroyed by oxidation, $2H_2O_2 = 2H_2O + O_2$.

Hydrogen peroxide is a very unstable body, and its solution is very bulky, so for convenience it is usually prepared as wanted from peroxide of soda. On dissolving this in water and adding acid, hydrogen peroxide is formed, thus:

Silk Bleaching.—Raw silk consists essentially of two substances: the true silk fibre or 'fibroin,' and the surrounding layer of silk-gum or 'sericin.' There are also traces of other substances. In order to develop the full beauty of the fibre the silk-gum must be removed more or less completely. This process, which is called the 'de-gumming,' is carried out by treating the silk (tied up in bags) in two or more hot soap-baths, which dissolve away the gum. The bleaching proper is carried out either by sulphuring or else by treatment with hydrogen peroxide as for wool. In order to save the great loss of weight caused by the total removal of the silk-gum (20-30 per cent.), other methods are frequently employed which leave a considerable proportion on the fibre and yet develop the valuable properties of the fibre to some extent.

Consult Duerr, *Bleaching and Calico Printing* (1896); Knecht, Rawson, and Loewenthal, *A Manual of Dyeing* (1910); *The Dyer and Calico Printer*; *The Journal of the Society of Dyers and Colourists*.

Bleaching Powder, a compound formed by the action of chlorine on dry slaked lime (see BLEACHING), was first manufactured on a large scale in Glasgow by Messrs Tennant & Co. The

use of chlorine for bleaching was introduced into Glasgow in 1789 by Watt, the engineer. At first it was used in the form of solution; but soon the addition of an alkali to the liquid was found to be beneficial, and the 'Eau de Javelle,' as this compound was called, was generally used. The next improvement was the substitution of lime for the alkalies, when Mr Charles Tennant in 1798 patented his *bleaching liquor*. In 1799 his partner proposed the use of dry slaked lime, and from that time to this the bleaching powder has remained unaltered in its nature. The manufacture of bleaching powder is one of the leading chemical industries of Great Britain, and at the present time it is looked on as the prop which supports many other industries, more especially the Leblanc soda manufacture. At one time the large quantities of hydrochloric acid gas produced in the manufacture of washing soda were allowed to escape into the air, destroying all vegetation for miles around. Restrictive acts of parliament, limiting the amount of gas which might be allowed to escape, resulted in the production of liquid hydrochloric acid, which was allowed, in many cases, to run into the streams. The manufacture of Chlorine (q.v.) and of bleaching powder utilised the by-product and became the nucleus of a very important industry; and on the introduction of the Brunner-Mond process for making soda, bleaching powder enabled old soda-works to make the bleaching powder pay for the loss on the soda they manufactured. For the decomposition of salt into sodium and chlorine, see SODA; see also HYDROCHLORIC ACID. An electrolytic or electro-chemical method of producing caustic soda and chlorine—i.e. from the decomposition of salt in water by means of strong electric currents—was begun on a commercial scale in 1894, and large quantities are produced thus at Niagara Falls. In the manufacture of 'bleach' the chlorine is passed into large stone or leaden chambers (60 feet long by 30 wide, and 5 high), on the floor of which a layer of dry slaked lime, about 6 inches deep, is placed, and this is allowed to remain in contact with the chlorine for some hours, during which time the temperature rises considerably. The greater part of the unabsorbed chlorine having been drawn into another chamber, the door is opened, and the lime stirred up with rakes to ensure uniformity, the strongest bleaching powder being found on the surface. Care is taken to transfer it to casks without exposure to wet or sunshine, as either of these is sufficient to induce decomposition and render it worthless. A more expeditious method of manufacture is now used, which originated in Germany, where the bleaching powder is made from electrolytic chlorine.

In either case, the resulting product consists of hypochlorite of calcium, CaCl_2O_2 , along with a variable proportion of chloride of calcium, CaCl_2 , and uncombined lime. Its value is judged (see CHLORIMETRY) by the amount of chlorine which it can give up for bleaching purposes, the present market strength varying from 33 to 39 per cent. of chlorine, or 'available chlorine,' as it is called. Bleaching powder is a grayish-white powder, with a powerful odour resembling chlorine. It rapidly absorbs moisture in a damp atmosphere, at the same time losing its bleaching properties. Rubbed with water in small quantity, it forms a thin cream; but on the addition of more water, thickens to a paste, which again becomes thin when more water is added. It is principally used in the bleaching of paper and linen; but as a disinfectant it is extensively applied in the purification of sewage or other obnoxious matter, its virtues from this as from every other point of view depending

on the freedom with which it liberates chlorine. In the manufacture of chloroform large quantities of bleaching powder are required, and no practical process for producing this substance has as yet been devised which can dispense with bleaching powder.

Bleak (*Alburnus lucidus*), a little fresh-water fish belonging to the great Carp family (Cyprinidae), in the Physostomi division of bony fishes, in which the air-bladder (if present) opens into the gullet. Roach, dace, and minnow are familiar allies. The body is elongated and compressed, and measures 6 or 7 inches; the mouth is directed upwards; the chin projects; the nature of fins and tail is shown in the figure. The upper surface is bluish green, the sides and under surface silvery, the fins white or transparent. The bleak is common in European

Bleak (*Alburnus lucidus*).

rivers north of the Alps, and especially frequents quiet flowing water. Its active motions on the top of the water are familiar to anglers on English rivers. These fish form a large part of the food of pike, trout, and such fishes. Cooked like sprats, they are a satisfactory dish. As in related forms, the scales are coated internally with a silvery substance, which has for many ages been used for producing artificial Pearls (q.v.) and the like.

Blebs (allied to *blow*, *bubble*), same as *Bulla* (q.v.).

Bled, VELDES, or GRAD, a Slovenian village of Yugoslavia, 30 miles NW. of Laibach, on a beautiful lake, has a castle, a pilgrimage church on an island, and lake and sun baths.

Bleeding, or HEMORRHAGE, is one of the most serious accidents which can happen to an animal, and constitutes the most anxious complication in surgical operations. As there is but a limited quantity of blood in the body (corresponding to about one-tenth of its weight), and as the sudden escape of a large portion of it is sufficient to cause death, every one should be instructed as to the measures which experience has shown to be the most efficient for preventing a dangerous loss of blood.

Bleeding may be from a wounded artery or vein, or from a capillary (minute vessel); and it may be in the form of a general oozing from the surface of a sore or a mucous membrane. We shall consider these varieties separately.

Arterial bleeding is recognised by the florid redness of the blood, and by its issuing from the cut vessel *per saltum* or by jerks. There are exceptions to this, however. When an artery has been tied, and bleeding occurs from below the ligature, the flow of blood is continuous, and of a dark colour.

If a large artery be severed, the first gush of blood may prove fatal, but more usually the patient faints, which implies a great diminution in the force of the circulation; and nature takes advantage of this respite to place the cut artery in circumstances as favourable as possible to the preservation of life—viz. the artery draws up within its sheath (see ARTERY); the blood, no longer impelled so vigorously by the heart, clots between the cut end of the vessel and the cellular tissue surrounding it; the inner and middle coats not only retract but contract, and another clot forms

within the arterial tube. These clots—which, with the faintness and the contraction and retraction of the artery, are termed natural *hæmostatics* ('blood-stoppers')—are sufficient in many cases to prevent a recurrence of the bleeding; but such a happy concurrence of circumstances is not to be depended on, and we must be prepared to adopt some of the many surgical or artificial means for restraining the flow of blood till Adhesion (q.v.) can occur between the cut surfaces of the coats of the artery. The principal surgical means are:

Immediate pressure, which may be applied by pressing the finger-tip on the place whence the blood is seen to flow. This may be kept up by pads of lint, or a coin of convenient size wrapped in cloth, and secured with a bandage to the part.

Pressure on the artery above, or as it comes to the cut part. This requires some knowledge of anatomy, but not more than any intelligent person may easily acquire. Thus, pressure on the inside of the upper arm, about midway between its front and back, will press the Brachial Artery (q.v.) against the bone, and arrest any bleeding from wounds of the forearm and hand. Pressure on the middle of the groin with a thumb placed crosswise will control the stream of blood in the femoral artery, so that none can escape from any wound of the lower limb below where the pressure is made. This pressure with the finger or thumb is very difficult to maintain with an adequate amount of firmness and continuity: hence it is well to substitute the handle of a door-key wrapped in cloth, for the direct pressure of the finger-tip, which rapidly becomes relaxed by fatigue.

Pressure on the course of the vessel may be very efficiently effected by tying a handkerchief (see *BANDAGE*) round the limb above where it is injured, and then inserting a stick next the skin and twisting. This is the principle of the original tourniquet, invented by Morel, a French surgeon, at the siege of Besançon in 1674. He got the idea from seeing how carriers tightened the ropes which secured bales of goods on their carts. It has been modified from time to time. At present it consists of a strong cylindrical strand of india-rubber long enough to encircle the limb four times; a chain attached at one end, a hook at the other. It is wound round the limb tightly, and the hook catches the link supplying most suitable pressure.

Pressure on the main vessel leading to a limb is only a temporary method of stopping bleeding, since it is not only very painful, but fraught with danger to the limb, which may mortify if it be too long continued. In a healthy man such pressure may be continued for five or six hours with impunity in case of urgent necessity, but a longer suppression of the circulation would almost certainly be followed by partial or complete death of the limb.

'Actual' cautery, or hot iron, is occasionally useful in bleeding from a bone, or at some points where pressure cannot be efficiently applied. It is the oldest method of stopping bleeding, and until the 18th century was much in use; but its abuse has almost banished it from the list of surgical hæmostatics.

Thermo-cautery is a hollow blunt platinum knife which cuts by burning through soft tissues (e.g. piles, tongue), stopping the bleeding as it progresses by sealing up the vessels. It is heated to cherry redness by pumping benzolene through its interior. Convenient and cleanly, it cuts soft parts speedily, and stops all three forms of hemorrhage.

Ligature, or tying the artery, is a very old method of arresting hemorrhage, and certainly the best. It was not used generally, however, in operations until improved anatomical knowledge and more efficient tourniquets allowed surgeons the time necessary for its application.

Another method was introduced by the late Sir James Y. Simpson of Edinburgh, and was termed by him *Acupressure* (q.v.), or pressure from a long needle or pin inserted from without, so as to press the artery between it and the tissues. The pins are removed after twenty-four or forty-eight hours. This plan promised to supersede the older kinds of ligature, especially in amputations, where the vessels can be easily secured, and where occasionally they are found so brittle from disease (see *ATHEROMA*) as to break under the pressure of a thread, but, since the introduction of the absorbable ligature, it has been entirely discarded in surgical practice. This ligature, consisting of catgut, prepared tendon, or silkworm gut, has the peculiarity that when placed around an artery and imbedded in the surrounding textures, it gradually becomes absorbed by the tissues around it, and does not require removal from the wound as was the case with the older silk or thread ligature.

Venous bleeding is recognised by the dark colour of the blood, and its continuous flow. Pressure is generally found sufficient to arrest it, and it should be applied *directly* over the wounded part. In this case, pressure higher up the limb only does harm, by retarding the return flow of the Circulation (q.v.), and thereby increasing the bleeding from the injured vein. It is hence very important to distinguish venous bleeding from that which occurs from arteries. In both, direct pressure on the bleeding point is the first imperative indication for treatment; in venous bleeding this suffices for the permanent arrest of the bleeding in most cases; in arterial bleeding it must be supplemented by one of the methods already described.

When a very large vein is divided, its two ends must be ligatured; if it be only partially severed, the surgeon can sew up the wound in its walls in many cases, and its function as an organ of the circulation is thus preserved.

Oozing from cut surfaces partakes more of the characters of venous than of arterial bleeding, and is called *capillary*—arising from the severance of vessels fine as a hair—as there is no vessel sufficiently large to demand the application of a ligature. The actual cautery or cold may be used, or one of the many styptics—e.g. perchloride of iron—may be specially recommended; it may be applied on lint or a sponge; or local astringents, such as alum and tannin. There are also puff-ball, felt, &c., which act mechanically, and owe their reputation chiefly to the pressure used in their application. The best remedy for this type of bleeding is the application of a steady stream of *very hot* water to the injured surface. If continuously applied at as high a temperature as the patient can possibly endure, rapid cessation of the oozing takes place. Some persons have a congenital tendency to bleed (the hemorrhagic diathesis); if such a one have a trifling cut, or have a tooth pulled, he bleeds perhaps to death. A prudent surgeon will not perform cutting operations on one of a hemorrhagic family unless unavoidable.

Bleeding from the free surfaces of mucous membranes occurs when they are much congested. One may have fatal hemorrhage from the stomach, and yet no open vessel may be found after death, even on the most careful examination. In such a case, we must trust to cold and internal remedies, such as acetate of lead combined with opium, gallic and tannic acids, and the extract of Witch Hazel (*Hamamelis Virginica*).

In bleeding, of whatever kind, the posture of the patient is a matter of great importance. The recumbent position is associated with a diminished force of the circulation, and should therefore be adopted in all serious cases. If the bleeding occur in one of the limbs, the raising of the injured part

is in itself often sufficient to cut short the loss of blood, and this postural treatment should in all cases be employed in addition to the special local remedies above described.

Bleeding from internal organs, as the stomach or the lungs, is a very serious symptom, and must be immediately and carefully treated whenever it occurs. In any such case, the patient should be placed in the recumbent position in a cool airy room, the dress loosened to allow of cooling of the surfaces of the body, and the application of cold further effected by placing wet cloths over the chest and renewing them as soon as they become warm from contact with the body. All these remedies have the effect of slowing and reducing the strength of the circulation, and the patient therefore loses blood less rapidly. A table-spoonful of turpentine mixed with a little milk should be administered by the mouth at once, and another table-spoonful should be added to a jugful of boiling water, and the patient caused to inhale the vapour from it. This acts directly on the blood-vessels, tending to close them at the bleeding point. Keep the patient very quiet, and summon medical aid as speedily as possible.

BLOODLETTING (also called Bleeding or Depletion, and including Phlebotomy or Venesection, Arteriotomy, Wet-cupping, Leeching, and Scarification) is a method of relieving the human system in states of general or local plethora by the abstraction of blood. General plethora is best treated, according to this method, by withdrawing a considerable quantity of blood from the arteries (arteriotomy) or veins (venesection). Local engorgement, or *hyperæmia*, of a part is usually treated by abstracting blood from the smallest-sized vessels, or capillaries, present in the skin, by the methods of scarification or leeching. In these cases, the removal of blood from the superficial textures diverts the blood-stream in part from underlying tissues, and thus reduces the tendency to inflammatory action in the deeper structures. In general bloodletting the object is to reduce the strength of the blood-stream throughout the whole system, and thus to diminish the acuteness of feverish conditions. The most usually employed method of accomplishing this is by the opening of one of the superficial veins of the arm, and allowing a sufficient quantity of blood to escape from the blood-vessel thus operated upon. The vein chosen for the operation is generally one of those near the front of the elbow-joint, which can be conveniently reached in this region without disturbing the patient, and which can be closed after the operation by antiseptic dressings with the elbow bent when the operation is completed. In performing the operation, it is first essential to make the vein stand out clearly under the skin, and to do so it is necessary to remember that the veins return the blood from the extremities to the trunk, and therefore that pressure must be applied constricting the arm above the elbow, thus causing the veins to swell from retardation of the blood-flow within their walls. A bandage is thus tied tightly around the middle of the upper-arm, and, as a result of its action, the veins in front of the elbow-joint commence to swell and stand out as blue cords, distinctly to be seen through the delicate skin of this region. Selecting the largest of these swollen veins, the operator places his left thumb upon it immediately below the point where he desires to open it. This prevents any backward flow of the blood in the vein, and renders it yet more distinct at the point where it is to be opened. Now taking a sharp lancet in his right hand, the surgeon pushes its point steadily downwards through the skin into the blue column that marks the position of the vein, taking care, however, only to divide its outer wall and not to

transfix it completely. Having by this means made a slit about half an inch long in its outer wall, he withdraws the instrument and removes his left thumb from the vein. A steady flow of dark blood now takes place from the wound; this is received into a graduated glass vessel, by which the operator may gauge accurately the amount of blood removed. Should the flow of blood tend to diminish, the patient is requested to grasp some hard object tightly with the hand of the side operated upon, and an immediate increase will occur in the blood flowing from the wound. When a sufficiency of blood has been abstracted by this means, the operator places a large and firm pad of lint over the wounded vein, and bending the arm at the elbow to a right angle, bandages it firmly in that position, observing specially that the pad of lint is tightly pressed against the wound in the skin. When the bandaging is complete, and only then, the constricting band around the upper-arm may be removed. There is danger in removing it earlier, since air may enter at the wound in the vein; and, being sucked upwards into the chest, may cause sudden cessation of the heart's action, and a considerable risk of immediate death. On account of this danger, it is not advisable for unskilled persons to attempt the operation. When the bandage and pad are firmly applied, and when the constricting band is removed, the patient's arm is placed in a sling and kept at rest for a week, when the wound in the skin and the vein is generally healed, and the patient may be permitted to use his arm again without incurring any risk. In children the veins in the arm are too small to be operated on satisfactorily, hence the external jugular vein of the neck must be selected in such cases; but the danger of the entrance of air is still greater in this region than in the arm; the operation should therefore be reserved for very urgent cases, and only performed with the utmost caution. The amount of blood actually abstracted in bloodletting must depend on the age of the patient and the nature of the case. The operation would be scarcely necessary if less than a quarter of a pint is to be removed, and it is now rare to remove more than one pint at one operation, however severe the case in which it is employed. For the methods and effects of local bloodletting, see CUPPING and LEECH. For the bleeding of animals, see PHLEBOTOMY.

Bleek, FRIEDRICH, a German biblical critic, born 4th July 1793 at Ahrensböck in Holstein, studied theology first at Kiel, and afterwards under De Wette, Neander, and Schleiermacher, at Berlin, where he was appointed in 1818 a university tutor, and in 1823 an extraordinary professor of Theology. In 1829 he was called to Bonn, and he remained there till his death, 27th February 1859. Bleek's chief work was his commentary on *Hebrews*, which theologians so different as De Wette and Delitzsch have ranked among the first exegetical works of its century. Schleiermacher declared that the '*Charisma* of Biblical Introduction' had been specially given to Bleek; his *Einleitung in das Alte Testament* (1860) and his *Einleitung in das Neue Testament* (1862) were translated into English by Venables and Urwick respectively, and re-edited (1886-93)—the former by Wellhausen and the latter by Mangold. Solid unpretentious learning and clear sober judgment equally distinguish these and his other posthumous works, which include his *Synoptische Erklärung der drei ersten Evangelien* (2 vols. 1862), and lectures on *The Apocalypse* (1862), on *Colossians*, *Philemon*, and *Ephesians* (1865), and on *Hebrews* (1868).

Bleek, WILHELM, philologist, son of the preceding, born in Berlin, 8th March 1827, studied

there and at Bonn, and accompanied Baikie's Niger expedition in 1854, but was compelled by ill health to turn back at Fernando Po. He went with Bishop Colenso to Natal in 1855, and after eighteen months' study of the Kaffirs, settled at Cape Town, where in 1861 he was appointed keeper of the Grey Library. Here he was engaged chiefly in philological investigations until his death, 17th August 1875. His writings on Bushman and Hottentot philology and folklore are important, and the *Handbook of African, Australian, and Polynesian Philology* (3 vols. 1858-63) shows remarkable erudition; but his most valuable work is the unfinished *Comparative Grammar of South African Languages* (1862-69). In 1912 appeared *Specimens of Bushman Folklore*, by Bleek and Lloyd.

Bleiberg, a village in the Austrian land of Carinthia, 8 miles W. of Villach, in the valley of the Drave, near the celebrated Bleiberg (Lead Mountain), has lead and lead-pigment works.

Blekinge is a province in Sweden, also called after Carlskrona (q.v.).

Blende (Ger. *blenden*, 'to dazzle'), a name given to a number of minerals composed chiefly of sulphur and of certain metals, all or almost all of splendid lustre, at least in fractures and the faces of crystals. It is also very often popularly applied more exclusively to one of these minerals, to which alone, perhaps, it originally belonged, Zinc Blende, Garnet Blende, or Sphalerite; also called, according to its chemical composition, Sulphide of Zinc. Among English miners it is known as *Black Jack*. It is abundant both in crystalline and in sedimentary rocks in many parts of the world, and is often associated with Galena (q.v.), or Lead-glance. It contains about 66 parts of zinc and 33 of sulphur, and is used as an ore of Zinc (q.v.); but the reduction of it is attended with difficulty, which much diminishes its value. It is usually brown or black, sometimes red, yellow, or green. It occurs both massive and crystallised in rhomboidal dodecahedrons, octahedrons, and tetrahedrons. Macles, or twin crystals, are remarkably common. It is very brittle; before the blowpipe it decrepitates violently, but only fuses on thin edges.—Manganese Blende is a rare mineral composed of sulphur and manganese.—Antimony Blende, or Red Antimony, is also a rare mineral composed of sulphur and antimony.—Ruby Blende is a name sometimes limited to Pyrargyrite or Red Silver (see SILVER, ORES OF), sometimes extended as a sort of generic term to include a number of other minerals composed of sulphur and metals, among which are Cinnabar, Realgar, and Orpiment.

Bléneau, a village in the French department of Yonne, 29 miles WSW. of Auxerre. Here Turenne gained a victory over the Prince de Condé in 1652.

Blenheim (Ger. *Blindheim*), a village of Bavaria, 23 miles NNW. of Augsburg, memorable in connection with Marlborough's great victory over the French and Bavarians, August 13, 1704. The battle, however, really took place at the neighbouring village of Höchstädt, and is known to the Germans by that name. France and Bavaria on the one hand stood opposed to England and Austria on the other. The French and Bavarian army consisted of 56,000 men, commanded by Tallard, Marsin, and the Elector of Bavaria. Opposed to it was an army of 52,000 men, under the command of Marlborough and Prince Eugene. The French and Bavarian generals had no idea that the allies would act on the offensive, and accordingly, when, about two o'clock in the morning, the line of the allies put itself in motion, they believed that it was about to retreat.

Even at seven o'clock, when the heads of the eight advancing columns became visible, Tallard regarded the whole proceeding as a stratagem to cover the retreat. When the mistake was discovered the army was hastily drawn up in battle-array, and fought with dauntless courage; but at five in the afternoon Marlborough broke through the line of battle, and won a victory most complete and decisive. The French and Bavarians lost between 30,000 and 40,000 in killed and wounded and prisoners, besides 120 pieces of cannon and 300 standards. The loss of the victors amounted to 5000 killed and 8000 wounded.—Near Blenheim the French defeated the Austrians in 1800.

Blenheim, capital of Marlborough district, New Zealand, near the coast, at the junction of two navigable rivers. There are gold-reefs in the neighbourhood, and the alluvial-mining is important. Pop. 4000.

Blenheim Dog, or MARLBOROUGH DOG, a small and very beautiful variety of spaniel, much resembling the King Charles breed in form and general appearance, but differing in the colour, which is white, with orange or flame-coloured markings. In weight it should not exceed 5 lb. The Blenheim spaniel is the *Pyrame* of Buffon. It derives its English name from Blenheim Park, in Oxfordshire, where the breed was a favourite one from the beginning of the 18th century.

Blenheim Park, near Woodstock, Oxfordshire, the seat of the Duke of Marlborough, erected at the public expense in the reign of Queen Anne as a testimony of gratitude to the victor of Blenheim. The sum, £500,000, that was voted for the purpose did not suffice for the completion of the work. The royal estate of Woodstock, in which it stands, was granted at the same time. The building was designed by Sir John Vanbrugh, and is a grand though heavy monument of his powers as an architect. The length of the principal front from wing to wing is 348 feet. The interior is proportionally magnificent, but its priceless collections of gems and paintings, and its library, were wholly or largely dispersed by auction between 1875 and 1886. Eleven of the pictures were offered to the nation for £350,000; amongst those acquired for the National Gallery was the *Ansidei Madonna* by Raphael, at a cost of £70,000. Among the objects of interest in the grounds are a triumphal arch, and a column 130 feet high, surmounted by a statue of Marlborough. An inscription on the pedestal, written by Bolingbroke, recites the public services of the hero. The park, 2700 acres in area and 12 miles in circuit, was laid out by 'Capability' Brown. Its trees are said to have been planted as the troops were ranged at Marlborough's victory; and a mighty bridge spans the rivulet Glyme, which then widens out into an artificial lake. See Marshall's *History of Woodstock* (Oxford, 1873).

Blennorrhœa (*blenna*, 'mucus,' *rheō*, 'I flow') is a medical term for an unusually copious discharge from any mucous membrane; but as it has been rather vaguely and inconsistently employed, most modern writers do not often make use of it. It has been used chiefly of discharges from the genito-urinary mucous membrane (see GONORRHOEA), from the conjunctiva, and the lachrymal sac (see EYE, DISEASES OF).

Blenny (*Blennius*), a genus of bony fishes, belonging to a large family (Blenniidae), in the division with spinous rays (Acanthopterygii). The family is characterised by Günther as follows: Body long, low, more or less cylindrical; naked, or with small scales; usually slimy. Dorsal fins extend along most of the back, often with prominent spinous rays. The hind fins are on the

throat, with few rays, and may be rudimentary or absent. The family includes 32 genera, with more than 200 species, widely distributed on the coasts of temperate and tropical seas, though some are found in brackish or even fresh water. The Sea-wolf or Cat-fish (*Anarrhichas*), with its formidable teeth; the slimy Butter-fish (*Centronotus*); the Viviparous Blenny (*Zoarces viviparus*), which brings forth its numerous young alive, and is popularly credited with being the parent of eels (*Ger. aal-mutter*); the brightly coloured Salaris; and many other interesting forms, belong to this family. They are carnivorous, and somewhat indiscriminate in their diet. There are but few British representatives.

The blennies themselves have moderately elongated, short-tailed, naked bodies. There is usually a tentacle over each eye. There are about 40 species, which are usually marine, though several live temporarily or constantly in more or less fresh water. They swim in small shoals, and can live on the wet shore for a much longer time than the absence of a tide. They are said to use their ventral fins in clambering among the seaweed. They are all greedy flesh-eaters. *B. gattorugine* is rare on British coasts, but abundant farther south. The Butterfly Blenny (*B. ocellaris*) is a quaintly

The Butterfly Blenny (*Blennius ocellaris*).

pretty little fish about 3 inches long, with flowing spines, and with an eye-like spot on its dorsal fin. It is most frequent towards the Mediterranean. The Smooth Blenny or Shanny (*B. pholis*), with similar distribution, has the spinous portion of the dorsal fin separate from the soft portion, and is of an olive-green colour irregularly marked with black spots. Like some of the others, it has in both jaws a long curved tooth, which it is said to use in detaching molluscs. There is no eye-tentacle. This organ is best developed in *B. tentacularis*, a Mediterranean form. *B. vulgaris* is found in fresh water in Italy, and also in the Rhone. The blennies are but rarely used as food, but their activity and hardness make them favourite inmates of aquaria. See Günther's *Introduction to the Study of Fishes*.

Blessing. See BENEDICTION.

Blessington, MARGUERITE, COUNTESS OF, was born September 1, 1789, at Knockbit, near Clonmel, Tipperary, where her father, Edmund Power, owned a small property. At the early age of fourteen she was forced into marrying a worthless Captain Farmer. She quitted him in three months' time, and in 1818, shortly after his death, married Charles Gardiner, Earl of Blessington. With him in 1822 she set out on a long tour on the Continent, where, as well as in London, she gathered around her all the most distinguished men of the time. In Genoa she formed an intellectual friendship with Lord Byron; afterwards she resided in

Paris, until the death of her husband in 1829. He left her a large fortune; and she held a little court of her own at her Kensington mansion, Gore House, Kensington, her celebrated soirées being frequented by many of her distinguished contemporaries. Her connection with Count d'Orsay (q.v.), which dated from 1822, placed her in an equivocal position as regards society, and her lavish expenditure overwhelmed her in debt, though for nearly twenty years she was making an extra income of more than £2000 per annum as author of a dozen most trashy novels. She was the authoress of *The Idler in France*, *The Idler in Italy*, and *Conversations with Lord Byron* (1834; new ed. 1894), which placed the poet in a more favourable light before his countrymen. At length in April 1849 she and D'Orsay had to flee from their creditors to Paris, and there on 4th June she died of apoplexy. See her *Life* by Madden (3 vols. 1855), and by Molloy (1896).

Bletchingley, an ancient town of Surrey, 5 miles NE. of Reigate, which till 1832 returned two members to parliament, though now a mere village. In the neighbourhood fuller's-earth is got.

Bletchley, a railway junction in Buckinghamshire, 47 miles NW. of London, 31 NE. of Oxford, and 45 SW. of Cambridge.

Blets, rotten spots in apples, pears, medlars, and other fruits.—*Bletting* is the first stage in the rotting of such fruits when the consistency of the fruit has altered, and the colour changed to brown, but before actual putrefaction has set in. The medlar is eaten in this state. See FRUIT.

Blewfields, BLUEFIELDS, ESCONDIDA, or RIO DEL DESASTRE, a river of the former Mosquito Territory, in Nicaragua, which, after a course of several hundred miles to the east, enters the Caribbean Sea in 12° N. lat. and 83° W. long. At its mouth is a good harbour, with a town—all named from a buccaneer captain, Blewfields.

Blicher, STEEN STEENSEN, Danish poet and novelist, born 11th October 1782, at Vium, a village of Viborg; studied at Copenhagen, became in 1819 pastor at Thorning, and in 1826 at Spendrup, in Jutland. Here he died, 26th March 1848. He was long known only as the successful translator of Ossian (1807-9), but his *Sneeklokken* (1826) and his *Jydske Romanzer* soon became widely popular, and were eclipsed by his *Nationalnoveller*. His poems are thoughtful, tender, and eminently national; and he left a humorous autobiography.

Blickling Homilies, Anglo-Saxon sermons (containing much legend) edited by Dr Richard Morris for the Early English Text Society in 1874, from the MS. at Blickling Hall near Aylsham in N. Norfolk.

Blida, a thriving town of Algeria, 32 miles SW. of Algiers by rail, which was ceded to France in 1837. The orange orchards produce 50 million fruits a year, which are mostly exported to France; and there is some trade in cotton, raisins, grain, tobacco, copper, and cork-wood. It suffered from earthquake in 1825 and 1867. Pop. (commune) 36,000.

Bligh, WILLIAM, an English admiral, born of an old Cornish family in 1753 or 1754, and celebrated in connection with the mutiny of the *Bounty*. He sailed under Captain Cook in his second voyage round the world, and earned early a high reputation as a skilful seaman. In December 1787 he was sent by the British government, as commander of the ship *Bounty*, to Tahiti, which he reached about ten months later, to collect plants of the bread-fruit tree with a view to their acclimatisation in the West India colonies. During their six months' stay on the island, his men had become

completely demoralised, and in a few weeks mutilated under the overbearing temper and harsh treatment of their commander. On 28th April 1789, Bligh, with eighteen men, was cast adrift in an open boat but 23 feet long, with a small stock of provisions, and without a chart; while the mutineers turned their own course back to Tahiti, and ultimately settled on Pitcairn's Island. After almost incredible hardship, Bligh arrived at the island of Timor, near Java, on 14th June, having with infinite skill and courage sailed his frail craft for 3618 miles. 'Bread-fruit Bligh' was again sent to collect bread-fruit plants, but though he was more successful, little came of the scheme. In 1806 he became governor of New South Wales, it being thought that his stern discipline might put an end to the unruliness of the New South Wales Corps, which had been a thorn in the side of previous governors. But he allowed personal dislikes to influence his conduct, and the corps mutinied against him early in 1808. He was kept under arrest in Sydney for a year, and then sent to England by way of Tasmania; at the end of 1809, however, he was by order of the British government reinstated for a day, and all official acts since the mutiny were cancelled. The officer who arrested him was tried in England and cashiered. Bligh, an admiral from 1811, died in London 7th December 1817. See Ida Lee, *Second Voyage of W. Bligh* (1920).

Blight, a diseased state of cultivated plants, especially cereals and grasses. The term has been very vaguely and variously used, having, in fact, been applied by agriculturists to almost every disease of plants in turn, however caused, especially when the plant dies before reaching maturity. See PLANTS (DISEASES OF), AMERICAN BLIGHT.

Blimbing, or **BILIMBI** (*Averrhoa Bilimbi*), an East Indian tree belonging to the Oxalidaceæ, cultivated in the Antilles for the sake of its wholesome and palatable fruit.

Blind. Blindness may arise from any cause intercepting the rays of light on their way to the optic nerve, or from disease of the optic nerve, or of that part of the brain connected with it. Blindness may vary in degree; it may exist from birth, or be the result of disease at any period of life. It may only be present during the day or the night, or a few weeks of the year, or it may be permanent. Only a few are born blind, although many lose their sight in infancy from preventable causes. One of the most frequent causes is ophthalmia neonatorum or the inflammation of the eyes of new-born babies, a disease which generally can be prevented, and always cured (see EYE). In almost all blind schools in England and the Continent, a third, and even more, of the pupils' blindness is caused by the neglect and unsuitable treatment of this disease. Eminent oculists state that half the blindness in Europe is due to this inflammation of the eyes of new-born babies. In 1914 ophthalmia neonatorum was made compulsorily notifiable in every sanitary district in England and Wales. Many become blind by accidents, smallpox, scarlet fever, measles, whooping-cough, or the various diseases of the Eye (q.v.).

The man who loses his sight after having had full use of it for years is profoundly to be pitied. Not merely has he lost that great gateway of knowledge, but it frequently happens that the loss of sight, for a time at least, shatters and enfeebles mental energy, and weakens the remaining senses and powers. Milton, blind himself, makes Samson say:

Now blind, disheartened, shamed, dishonoured, quelled,
To what can I be useful? wherein serve
My nation, and the work from heaven imposed?
But to sit idle on the household hearth,
A burdensome drone, to visitants a gaze,
Or pitted object.

The man born blind is in many ways still worse off: he cannot in the least imagine to himself what it is to be able to see; colour and visual form are unknown to him (see VISION). Locke's blind man who imagined that 'scarlet was like the sound of a trumpet,' made but a very random shot. Nor is it true that the blind man's other senses are preternaturally acute, and that blind people are always good musicians. A blind boy, under proper training, can indeed have his senses of touch and hearing developed to a state of exceeding acuteness, though they can never make up for the lost faculty. A blind boy who can read with the first finger of each hand, will be as unable as the seeing to use the other fingers for reading, unless he has practised with them. Without careful training and persevering industry, the blind cannot attain even creditable proficiency in music. Amongst blind men and women, some of them blind from infancy, who have more or less completely triumphed over their disadvantages or been otherwise famous may be named Homer (possibly); Blind Harry; John Milton; the Cambridge professor, Nicholas Saunderson (q.v.); Dr Blacklock; Leonard Euler; John Metcalf of Knaresborough, road surveyor (blind from six years of age); Holman, the blind traveller; Huber, the naturalist; Prescott, the historian; Rev. George Matheson, D.D.; Rev. W. H. Milburn, chaplain of the United States Senate; John Stanley, Mus. Doc. Oxon; Edward Rushton; Maria Thérèse von Paradis; Elizabeth Gilbert; Louis Braille; Sir George Macfarren; Dr Wm. Moon; Dr T. R. Armitage; Sir Francis J. Campbell; Professor Fawcett; and Sir Arthur Pearson. The blind have at various times suffered under special legal disabilities—for example, as to acting as witnesses and as to succession to fiefs and thrones; by the canon law a blind man was disqualified for holy orders.

At successive censuses the number of totally blind persons in the United Kingdom was:

	1851.	1861.	1871.	1881.	1891.	1901.	1911.
England and Wales.....	18,806	19,352	21,500	22,882	23,467	25,317	26,886
Scotland.....	3,010	2,820	3,019	3,158	2,797	3,258	3,817
Ireland.....	7,587	6,879	6,847	6,111	5,841	4,253	4,812

At the same dates the number of the general population to each blind person was:

	1851.	1861.	1871.	1881.	1891.	1901.	1911.
England and Wales.....	979	1037	1052	1138	1236	1255	1370
Scotland.....	1065	1090	1112	1182	1439	1875	1435
Ireland.....	864	843	852	847	881	1048	1018

The great number of aged blind in Ireland is doubtless due to an ophthalmic epidemic during the Irish famine.

The decrease may be fairly attributed to the progressive improvement in surgical treatment of affections of the eyes, to the diminished prevalence of such diseases as smallpox, to which a considerable amount of blindness was formerly due, and the lesser prevalence or more efficient treatment of purulent ophthalmia, and other infantile maladies which result in blindness. Another cause of decrease is probably the improvement of the health of the community due to better sanitation.

In the United States in 1910 the enumerators reported approximately 61,500 as blind, but from registers compiled in the different states it is estimated that 100,000 is a nearer approximation.

Institutions.—The first institution for the blind of which we have any record was a hospital merely—namely, that founded by St Louis at Paris in 1260 for 300 blind persons. The common legend is that

he founded it as an asylum for his soldiers returning from the crusades, but the statutes of the founder are preserved, and no mention is made of crusaders. There have been many such hospitals, where no attempt at education was made. The first book calling attention to the condition of the blind was published in Italy in 1646, and from that time there was increasing interest in the subject. Jacques Bernouilli (q.v.), in 1676, taught a blind girl several branches of science, and also how to write; and this led him to publish *A Method of Teaching Mathematics to the Blind*. But it was Valentin Haüy of Paris who, in 1784, made the first successful attempt to educate the blind. To him is due the honour of instituting a movement which has resulted in the establishment of institutions for education, and workshops for the training and employment of the blind in all civilised countries. Before the end of the century the following institutions were opened in this country: School for the Indigent Blind, Liverpool, 1791; Royal Blind Asylum and School, Edinburgh, 1793; School for the Blind, Bristol, 1793; School for the Indigent Blind, London, 1799. Since the beginning of the 19th century many institutions for the blind have been opened in the United Kingdom.

School Boards and Local Education Authorities.—The School Board of Glasgow was the first to take up this work, but London subsequently took the lead, and adopted a comprehensive and systematic plan. The blind children attended board schools, but received special instruction at thirty centres. The Report of the Royal Commission on the Blind (1889) led to the passing in 1893 of an Elementary Education (Blind and Deaf Children) Act, under which their education became compulsory between the ages of five and sixteen. The Local Education Authorities were made responsible for the provision of instruction up to the age of sixteen, and annual grants were contributed by the Board of Education. Similar provision is made for Scotland. This act led to an increase in the number of residential schools, and the establishment of day schools for blind children in some of the large towns. Separate classes for children suffering from a high degree of myopia have also been formed. The Blind Persons Act of 1920 requires education authorities to provide for the technical training of the blind.

Schools, Workshops, and Homes.—When the institutions for the blind were first established in the United Kingdom, they were often a combination of school, workshop, and asylum. This association of the youthful and adult blind is most undesirable, and a notable change has been their separation. In some instances the schools have been removed from crowded city quarters to the country. Under the Blind Persons Act local authorities must make arrangements for the welfare of the blind, and may provide workshops, hostels, &c.

Home-teaching Societies.—There are home-teaching societies in all the large towns in the United Kingdom; and the blind, even in country districts, are visited. Most of these societies assist in other ways. The Indigent Blind Visiting Society, founded in 1834, visits, educates, and relieves the blind at their own homes, independently of asylums. It is the great missionary society to the blind of London.

Pensions.—In the United Kingdom the principal societies that help the blind by granting pensions are Hetherington's, Day's, the Clothworkers', the Cordwainers', Royal Blind Pension Society, and Indigent Blind Visiting Society. The Gardner Trust administers the income of £300,000 left by Mr Henry Gardner in 1879. It is used for instruction in music, for pensions, and for grants for special purposes. By the Act of 1920 Old Age Pensions begin for the blind at fifty.

Unions of Institutions, Societies, and Agencies

for the Blind.—Unions covering the whole of England and Wales have been formed to organise, co-ordinate, and extend work on behalf of the blind; to stimulate the prevention of blindness; to encourage the after-care of pupils leaving institutions; and to promote employment. A 'union of unions,' consisting of elected representatives from each union, promotes unity of action. In Scotland the work of the unions is covered by home-teaching societies and outdoor missions.

National Institute for the Blind.—In 1868 Dr T. R. Armitage, aware of the great improvements which had been made on the Continent and in America, founded the British and Foreign Blind Association to promote the education and employment of the blind, by ascertaining what had been done in this and other countries, and by attempting to bring about harmony of action between existing schools and institutions. The association soon gained information through its corresponding members of what was being done abroad, and published a report. The executive council of the association endeavoured to induce the various institutions to adopt the best methods and systems of education, and was indefatigable in its efforts to improve and cheapen the apparatus, books, maps, &c. used by the blind. Under Mr Henry Stainsby, secretary-general from 1908, many important improvements have been introduced, notably in the method of embossing and printing books in the Braille type. Mr H. M. Taylor established a fund for the production of scientific books. In 1914 the Armitage Hall, part of a new commodious building, was opened. At that time the name of the association was changed to the National Institute for the Blind. Sir C. Arthur Pearson, president and treasurer, raised a large endowment fund for printing books in embossed type.

Departmental Committee.—In 1914 a Departmental Committee was appointed to consider the condition of the blind in the United Kingdom, the means available for their industrial and professional training, and their assistance. The Great War had greatly augmented the number of the blind when the committee reported in 1917. It recommended more active intervention of the state, by means of a special department under the Ministry of Health, to secure central control, organisation, and assistance for existing voluntary agencies, and additional assistance for the blind. It drew attention to the very adequate provision for blinded soldiers and sailors at St Dunstan's Hostel, and to the National Institute's care for the future welfare of the inmates. In conclusion, it referred to 'the extremely hopeful nature of the problem,' and the probability of gradual and permanent reduction in the number of the blind. Advisory committees were set up, which co-operated with the National Institute and government departments. The Blind Persons Act of 1920 was the outcome of this policy.

United States.—In the United States every blind child has a right to be educated at the expense of the state. Some of the best institutions are, however, founded and partly maintained by private benevolence. In a number of the states permanent commissions on the blind have been appointed, whose efforts have been chiefly directed to registering the adult blind, and as far as possible providing employment for them. They have started an active propaganda for the prevention of blindness, and a national association for the 'Conservation of Eyesight' has been formed. Its aims are: (1) the prevention of infantile blindness; (2) the prevention of blindness from industrial and other accidents; (3) the conservation of vision through improved hygiene during school-life and in industrial occupations. The Russell Sage Foundation has made an appropriation for this field of work.

The following table furnishes statistics of other countries :

	Number of Blind
Australia (1901).....	2,784
Belgium (1910).....	3,228
Bulgaria (1905).....	5,319
Canada (1910).....	3,283
Chile (1901).....	2,601
Denmark (1911).....	1,595
Egypt (1907).....	148,280
In one eye.....	368,702
France (approx.).....	82,000
Finland (1900).....	3,229

South Africa (1910).....	6,550
Europeans.....	976
Sweden (1900).....	3,413
Switzerland.....	2,107
United States (1910), totally blind (approx.).....	61,500

In 1784 Valentin Haüy commenced the first printing in raised characters for the blind, and founded the Institution Nationale des Jeunes Aveugles, which was the first, and still holds its place among the best-managed schools for the blind in the Old and New Worlds. The character he chose was the Italic, or written form of the Roman letter. Founts of types were cast and books printed; and having been approved by the Academy of Sciences, and exhibited before the royal family at Versailles, the art created at the time a great sensation.

Gall's Type.—James Gall of Edinburgh saw specimens of Parisian books in 1826, and was deeply impressed with the importance of putting the Bible into the hands of the blind to employ their vacant hours. Being himself a printer and publisher, he resolved to improve the alphabet so as to make it more tangible. In 1827, after much study and many experiments, Gall printed his 'first book' for teaching the blind to read, in a triangular modification of the common alphabet, of which the following is a specimen :

BEKOLD THE LAMB OF GOD

This was followed by other little volumes, including a series of Scripture statements and a condensed epitome of Old Testament history. These were received with so much favour that in 1829 he issued a prospectus for the publication of the Gospel of St John, at one guinea, which was to pay not only for the copies, but preliminary expenses. This work was printed in 1832, but was not published until 1834. In 1832 the Scottish Society of Arts offered a gold medal, value £20, for the best alphabet for the blind. The award was not made till 1837. Sixteen arbitrary alphabets had been sent in, all of which were rejected, and the prize was awarded to a Dr Fry of London, who had suggested the use of Roman capitals, which were introduced in America in 1834. Great interest began to be excited throughout Britain, and extended even to foreign countries. Abbé Carton was sent by the Belgian government to visit Gall's establishment, and returned to set up a printing-press in Brussels. Gall was anxious to improve the printing and lessen the cost; the most important improvement consisted in the use of serrated types, by which the letters were formed of dots instead of lines, thus :

BEKOLD THE LAMB OF GOD

In 1836 he offered to print in the improved type as an ordinary business transaction, without subscriptions or donations. Of this offer the London Sunday School Union, the Religious Tract Society, and the British and Foreign Bible Society availed themselves in 1837; and in 1838 he printed for the last mentioned the Gospel of St Luke and the Acts of the Apostles.

As the institutions for the blind in those days 'had not hitherto,' as they expressed it, 'patronised any device of this kind,' Gall had to contend with all the apathy and incredulity which every new thing has to encounter. But now the tide had turned; readers were multiplying over the country, schools for the blind were beginning to be formed, the institutions abroad had all 'patronised the device,' and printing-presses were busy both in America and on the Continent; so that when the Sunday School Union, the London Tract Society, and the British and Foreign Bible Society began to publish class-books, tracts, and Bibles for the blind, they all became convinced of its importance.

Howe's or Boston.—Dr Howe, from Boston, visited Scotland, and having received from Gall all the information which he could supply, established on his return to America a printing-press in the Perkins Institution. In 1834 he published the Acts of the Apostles, and completed the New Testament in 1836. About the same time Friedlander of Philadelphia published the Gospel of St Mark. Friedlander unfortunately adopted the capital alphabet. Dr Howe, on the contrary, had adopted an angular modification of the common alphabet, similar to, but much smaller than, Gall's, and with that printed the whole Bible, besides an ever-increasing number of other volumes in all departments. The following is a specimen :

BEHOLD THE LAMB OF GOD

For many years Howe supplied books for all the institutions in the United States.

Alston's.—John Alston of Glasgow, who established a printing-press in the Blind Asylum, of which he was treasurer, printed in 1837 the Gospel of St Mark in the same type in which (unknown to him) it had been printed in 1834 by Friedlander. Through his influence it was at once adopted in the other institutions throughout the kingdom; and, having thrown himself with much enthusiasm into the work, he very soon raised funds by which he completed the New Testament in 1838, and the whole Bible in 1840. To him, therefore, belongs the honour of having printed the first complete Bible for the blind in any language, because Howe, although he commenced the work earlier, did not finish it till 1842. The effect was immediate and decisive; rivalry was extinguished, hundreds of the blind were brought under instruction, and reading was thenceforth acknowledged to be a necessary department of the education of the blind. Alston, encouraged by the decision of the Scottish Society of Arts, which he himself helped to influence, made a fatal error in adopting Roman capitals. Reaction very soon took place, the blind themselves being the first to rebel. The want of sufficient legibility was, in their judgment, a fatal objection, and outweighed all other considerations. Even the large amount of money that had been expended, and the extensive libraries that had been formed through Alston's energetic labours, they were prepared to sacrifice, in order to obtain books which they could read with ease.

Lucas's.—In 1838 Lucas of Bristol introduced an ingenious shorthand, and for many years it was used by the London Society for Teaching the Blind

to Read. The characters are arbitrary, consisting mainly of lines with or without a dot at one end.

Frere's.—Frere also introduced his shorthand system about 1838. The embossed characters were only an application of his phonetic system for the seeing, which he hoped would become general. His characters consist of straight lines, half-circles, hooked lines, and angles of 45 degrees, together with a hollow and solid circle. Frere employed 'return' lines; that is to say, the lines read 'boustrophedon,' the letters themselves being reversed in the return lines. He devised a cheap and very ingenious method of setting up and stereotyping his books. The letters, formed of copper wire, are laid on a tin plate, previously washed over with a solution of zinc; when heat is applied to the under-surface, the letter becomes soldered on to the plate, and such plates produce extremely good printing. Both Moon and Lucas adopted this system of stereotyping.

Moon's.—Dr Moon of Brighton, whose system is used more than any other by the older blind throughout the country, adopted an arbitrary alphabet, some of the characters resembling or suggesting the letters which they represent. He also adopted Frere's return lines, but did not reverse the letters.

Braille.—Towards the middle of the 19th century the intelligent blind in all parts of the world began a very earnest protest against the various line-types, which had been arranged with as much regard to the seeing as the blind. In a short time the question became one of dots *versus* lines. It was then that the great invention of Louis Braille was recognised. He had published a system in 1829, and fully developed it in 1834. His blind friends and co-workers immediately recognised its superiority over the Roman letter, but the school authorities of the Institution Nationale des Jeunes Aveugles would not change the old system. It was not officially adopted in Paris until 1854, two years after the death of its inventor.

Louis Braille (1809-52) was born at Coupvray, about 23 miles from Paris. He became blind through an accident at the age of three. In 1819

too long vertically to be covered with the finger. Braille worked upon it until he devised the simple and beautiful system which bears his name. His signs are arbitrary, and consist of varying combinations of six points placed in an oblong. There are sixty-three distinguishable combinations of these, so that after providing an alphabet there remain signs for punctuation, contractions, &c.

The group of six dots, which is the largest number of points that any letter can consist of, is divided into upper, middle, and lower pairs. The first ten letters, from *a* to *j*, exhaust all possible combinations of the upper and middle points. The next ten, from *k* to *t*, are formed from the first by adding a lower back point to each. Thus, *a* becomes *k*, *b* becomes *l*, &c. The third row is similarly formed by adding two lower points. Thus, *a* becomes *u*, *b* becomes *v*, &c.

The fourth row of letters is formed from the first by adding a lower front point to each of the first row. The only letter of the ordinary alphabet in this row is *w*, which is derived from *j* by adding a lower front point. This is a consequence of the French origin of the system.

In Egypt the Koran has been printed in Braille type, and a blind person can earn a good livelihood by reading it at funerals and on other occasions. Mr Murray, a Scottish missionary, ingeniously adapted the Braille system for printing Chinese.

Braille Writing-frame.—For writing, a frame is used consisting of a grooved metal bed, containing ten grooves to the inch; over this is fitted a brass guide, punched with oblong holes, whose vertical diameter is $\frac{3}{4}$ ths of an inch, while the horizontal diameter is $\frac{1}{2}$ ths. This perforated guide is fixed into a light wooden frame, like the frame of a slate, which is attached to the grooved metal bed by hinges. The paper is introduced between the frame and the grooved bed. The instrument for writing is a blunt awl, which carries a little cap of paper before it into the grooves of the bed, thereby producing a series of little pits on the side next the writer. When the paper is taken out and turned over, little prominences are felt corresponding to the pits on the other side. The reading is performed from left to right, consequently the writing is from right to left; but this reversal presents no practical difficulty as soon as the pupil has caught the idea that in reading and writing alike he has to go forwards. The brass guide has a double row of openings, which enables the writer to write two lines; when these are written he shifts his guide downwards until two little pins, which project from the under surface at its ends, drop into corresponding holes of the frame, when the writer writes two more lines; and this operation is repeated until he arrives at the bottom of the page. This description applies to the writing-frame used in France and most parts of the continent of Europe.

The English frame is somewhat different. In it the bed is not grooved, but is marked by groups of little pits, each group consisting of six. These are arranged in two parallel lines, and the guide is hinged on this bed in such a way that when the two are locked the openings in the guide correspond exactly to the pits in the bed. When the first two lines have been written, the guide and bed travel as one piece down the board, which is so arranged as to give the right distances between the lines. Each line is separated from the next by a wide interval, which greatly facilitates reading; when the first page has been written the paper is reversed, and the lines of the second page are written in the intervals between those of the first. A simple mechanical arrangement enables a blind person to do this with ease and certainty. This interlined writing not only makes the writing far more legible than that produced in the original

THE BRAILLE ALPHABET, WITH CONTRACTIONS.

The large dots represent the raised points of the Braille letter; the small simply serve to indicate their position in the group of six.
The signs of the 2d, 3d, and 4th lines are formed from those of the 1st by the addition of lower dots

he became a pupil of the Institution Nationale des Jeunes Aveugles at Paris. In 1826 he was elected a teacher at the institution, where he had distinguished himself as a pupil. As pupil and as teacher he laboured to invent a system which the blind could not only read, but write in relief. He had been trained as a boy to read the line-type; after examining all systems, including arbitrary characters, he became convinced that the one best adapted to reading and writing was Barbier's. Barbier's letter contained six points, but was

French frame, but also effects a saving of space amounting to about 20 per cent.

Soon after the founding of the British and Foreign Blind Association, Dr Armitage, the indefatigable honorary secretary, said: 'After the most determined opposition, the Braille system, which is the foundation of all real education for the blind, has been pretty generally adopted by the schools of the United Kingdom, and the work of the association

has, to a great extent, contributed to produce the same result in Germany.'

New York Point.—A modification of the Braille, known as New York Point, has been adopted in the United States. The long diameter of the full letter of six points is horizontal instead of vertical (: :), the letters recurring most frequently being represented by the smallest number of points

American or Modified Braille.—A modification

ALPHABETS USED BY THE BLIND.

of English Braille is used also in nearly half the schools for the blind of the United States. In this system also the signs are rearranged so that the letters of the alphabet recurring most frequently are represented by characters containing the fewest dots, and different contractions have been adopted.

Braille Musical Notation.—Braille furnishes a musical notation as easy to learn as the ordinary staff notation. Any music whatever can be written. In instrumental music a serious disadvantage arises from the fact that the blind performer has both to read and play with his hands; the usual plan is to read with one hand and play with the other, until the music is committed to memory. As care is taken not to reproduce what is already in print in other countries, blind musicians have now a very large and varied library, which is daily extending.

A Uniform Type.—At a conference of the America Association of Workers for the Blind held at Saginaw, Michigan, in 1905, it was felt the time had come when a determined effort should be made by the blind themselves to settle this vexed question of types, and save the waste of money which arises from embossing the same book in several different systems. A committee of representative blind men was appointed to examine the different systems of dotted type, and try to determine what are the fundamental principles which must underlie an embossed system in order that it may best accomplish its mission, to devise a code based upon them, and to secure its general adoption. It is confidently believed that a system devised in accordance with the finding of the committee will be adopted in all the schools for the blind in America. By consultation with workers for the blind in Great Britain, it is hoped to secure their co-operation in the adoption of one uniform system for the English-speaking blind of the world.

Printing.—The printing for the English-speaking

blind is done principally by the American Printing House for the Blind, Louisville, Kentucky, U.S.A.; the Howe Memorial Press, Perkins Institution for the Blind, Boston, U.S.A.; Dr Moon's Printing Establishment, Brighton; and the National Institute for the Blind. The American Printing House has a subsidy from the American government, and the institutions in the United States have the right to order books in any type. Embossed books are produced in various ways, in France generally from movable type. In America the printing was formerly done from electro-plates or stereotype-plates, made from forms of movable type set up by hand. For many years the British and Foreign Blind Association printed from brass plates. A sheet of brass folded upon itself was placed in a strong frame and embossed by means of a punch and hammer, in a similar way to that in which a style would be used in writing a single sheet of paper. The first complete copy of the English Bible in Braille, requiring 39 large foolscap volumes, was produced between 1877 and 1890, and every dot of the 6000 sheets, punched by hand, was the labour of one man. The invention of the stereotype-maker in 1893, by Mr Frank Hall, late superintendent of the School for the Blind, Illinois, U.S.A., has revolutionised the method of preparing embossed plates. This machine, which punches at a stroke characters composed of several dots, can be driven by electric power, and thus produces quickly embossed plates ready for printing. It has led to a greatly increased supply of books, as all the large schools in Great Britain and America print books and music for their own use. At the National Institute improved printing-presses driven by electric power have been set up, on which the embossed plates open and shut automatically to receive the paper; by the new method 6000 single pages can be printed in an hour, against 320 by the old press.

Formerly each sheet of paper was damped before printing, and the drying process was cumbersome and lengthy. The books are now printed on specially made sulphite paper, which softens as it comes in contact with electrically-heated plates, and as quickly hardens when it leaves them.

Libraries, &c.—Embossed books are now placed on shelves of the public libraries in many large cities of Great Britain and the United States. The public library at Oxford has many volumes of classical and standard works for the use of the university students. The Incorporated National Lending Library, London, was founded in 1882. Books are forwarded to all parts of the United Kingdom at a reduced rate of postage. In the United States, Canada, and Australia such books are carried free of charge.

Apparatus.—By means of the optophone the blind can read ordinary type by ear. Writing-frames are of many patterns. Paper with raised lines and corrugated cardboard are used for correspondence, but any of the typewriters constructed for the seeing can be used with equal facility by the blind. A Braille code of shorthand was elaborated at the Birmingham institution, and a machine for writing it was invented by Messrs. Stainsly & Wayne of that city. A knowledge of this code and the use of this machine enable blind persons to secure positions as shorthand typists. There are a number of machines for writing Braille. For working arithmetical sums many ciphering-boards have been constructed, but the best is the octagonal board introduced by the Rev. William Taylor of Worcester. For school purposes good and very cheap maps are produced by the National Institute, and by Herr Kunz at Illzach, Alsace. Mr Frank Hall also invented a machine for map-making, which is used in some schools for the blind.

Trades.—The handicrafts which are usually pursued in the principal workshops of the United Kingdom are the making of baskets, brushes, brooms, bedding, upholstery, wire-work, boot and shoe repairing, making of mats, ship-fenders, ropes, sacks, chair-caning, wood-chopping, &c.; for girls, typewriting, massage, the making of fancy baskets, brushes, chair-caning, hand and machine sewing, knitting, netting, crocheting, &c. Of all trades, pianoforte-tuning is the best; but the blind can only succeed as pianoforte-tuners when they are first-class workmen.

In the United States broom-making, under favourable conditions, proves very remunerative. The Germans have not adopted our workshop system for the blind, but the best institutions, especially of Saxony, continue to keep a methodical supervision over their pupils, even in the country districts, after they have left the institutions. It is claimed that by this system a much larger proportion of the blind become independent members of society. Active friends of the blind in all countries would do well to acquaint themselves with the details of the Saxony system.

Professions.—A considerable number of blind persons have passed through the leading universities of Britain and other countries, and have won by their talents and energy honourable positions in the church, medicine, law, politics, and commerce. There is a Fawcett Memorial Scholarship tenable by blind persons for four years at any of the universities of the United Kingdom, including women's colleges. Four university scholarships are granted by the Gardner Trust. In some parts of the United States a government grant is made to defray the expense of a sighted reader for blind students at the university.

Music.—Music in its various branches offers the best and most lucrative employment for those among the blind who, from an early age, can have

suitable educational privileges. The Royal Normal College and Academy of Music for the Blind has shown by practical results what is possible in the profession of music. The education in the college is not limited to music: to a casual observer it would seem that music occupied almost a secondary place. The first aim is mainly character, healthy bodies, well-cultivated and active minds, and prompt, business-like habits, which qualify its pupils for practical life. The pupils are taught swimming, skating, rowing, cycling, gymnastics, military drill, and in the season a great variety of outdoor sports. The college embraces a preparatory school with classes in Kindergarten and modelling, a secondary school, a training-college, a technical school, and an academy of music.

Blind, KARL (1826-1907), author and revolutionist, was born at Mannheim, and studied law at Heidelberg. For his share in the risings in South Germany in 1848 he was sentenced to eight years' imprisonment, but liberated by the populace, found an asylum first in Belgium, and afterwards in England, where he took an active part in democratic propaganda. An enthusiastic advocate of German freedom and unity, he promoted the Sleswick-Holstein movement. As an author he wrote on politics, history, and mythology, including lives of Ledru-Rollin, Deák, Freiligrath; also volumes and magazine articles on such subjects as Fire Burial, Yggdrasil, Water Tales, Shetlandic and Welsh Folklore, The Siegfried Tale, and The New Conflict in Germany.—**MATHILDE BLIND** (1847-96), born the daughter of a banker at Mannheim, adopted her new name when Karl Blind married her mother, and became a champion of woman's rights and an accomplished and remarkable English poetess, amongst whose works *The Prophecy of St Oram*, *The Heather on Fire*, and *The Ascent of Man* were specially noteworthy.

Blind Fish. In the darkness of caves and of the great oceanic depths there are sometimes blind fishes. The eye may be visible but very small, or it may be quite hidden. There is usually a compensatory development of tactile organs. It has been shown by experiment on the goldfish that prolonged imprisonment in darkness is followed by deterioration of the eyes, but it is probable that the blindness of the cave-fishes and some deep-sea fishes has come about much more indirectly through germinal variations of a retrogressive kind. The American blind cave-fishes, such as *Amblyopsis*, have near relatives in exposed fresh-water streams; the Cuban blind cave-fishes, *Lucifuga* and *Stygicola*, are of marine origin. In the sea the eyes of

fish are large in proportion to the depth inhabited, down to 200 fathoms; big eyes are needed to make the most of the scanty light. Below the light-limit large-eyed forms occur, probably utilising the gleams of phosphorescence, or small-eyed forms with greatly developed tactile organs. In the greatest depths, however, as the result of the *Challenger* Expedition demonstrated (see Gunther's *Challenger Report on Fishes*), fishes with rudimentary eyes occur, as one would indeed expect. See CAVE ANIMALS, ENVIRONMENT, FISHES.

Blind-gut. See CÆCUM.

Blind Harry. See HARRY.

Blindheim. See BLENHEIM.

Blindness. See BLIND, COLOUR BLINDNESS.

Blindstory, another name for the Triforium (q.v.), so called as opposed to the Clearstory or Clerestory (q.v.) of a church.

Blind-worm, or SLOW-WORM (*Anguis fragilis*), a limbless lizard, in the Skink family. The form is worm-like, tapering slightly in the tail; only internal traces of limbs are present; the tail occupies about half the total length; the nostril is situated in a shield; the eyes are small but quite serviceable; the eyelids are scaly and movable; the earhole very small and hidden; the teeth borne on the jaws are long, pointed, and directed backwards; the tongue is scaly in front, with slender warts behind; the scales are smooth, and those of the head very distinctive. The colour varies considerably with age; the young are whitish above with

Blind-worm.

a median black stripe, but black on the sides and below; the adults are brownish above and black below, often relieved by longitudinal lines. The full size is about a foot, about half of which goes to the tail, but large specimens may measure a foot and a half or more. The blind-worms are shy animals, living among bushes, and coming out at night in search of earth-worms and white slugs. They give a feeble bite, but are perfectly harmless. So timid are they that they become rigid when caught, and in this state an attempt to bend the greatly contracted muscles results in a breakage. The body divides in two, as the specific title *fragilis* implies. The young are born alive in midsummer to the number of 8 to 26. In winter they hibernate in holes in the ground, not alone, however, but in companies of two dozen or so. The blind-worms are found all over Europe, except in Sardinia and the northern regions, and are also known in North Africa and Western Asia. They appear to be hardy animals, and have been found more than 3000 feet up the Alps. They occur, though not abundantly, in Britain. Brehm's *Tierleben* (new edition) gives an interesting account of them. It need hardly be said that they have no special connection with serpents, though similarity of habit has come to be associated with a superficial external resemblance. As true lizards they must also be distinguished from the much rarer amphibian *Cæcilia* (q.v.), to

which—also neither worms nor blind—the name blind-worm is also sometimes applied.

Blister-beetle, a popular name for a number of beetles in a family of Coleoptera known as Vescicantia, or in two distinct families, Meloidæ and Cantharidæ. The name refers to the vesicating or blister-raising properties of their body-juice. The Spanish-fly and the Oil-beetle are familiar illustrations. As to the zoological characters of the family, the antennæ are usually 11-jointed, the head depressed with a narrow neck, the front shield narrower than the flexible wing-covers, the claws split into two usually unequal portions, the abdomen with 6 to 7 free rings. They are usually brightly coloured, especially at home in warm countries, include about 800 species, and almost always possess the blistering property above noticed. The life-history is often very remarkable. The larvæ live parasitically on bees, on grass-hopper or locust eggs, &c., and seem to pass through an unusual number of changes, to which the name 'hyper-metamorphosis' has been applied. It is not merely that the larvæ begin life lean, horny, and 6-footed, and soon become fat, soft, and footless, but that before passing into the pupa stage, they pass through a series of preparatory changes. The important genera are: (1) *Lytta* or *Cantharis*, (2) *Mylabris*, (3) *Cercocoma*, (4) *Meloe*. In regard to some of these, a few notes are requisite. (1) The genus *Lytta* or *Cantharis* has wings, long, thread-like, 11-jointed feelers, and kidney-shaped eyes. It includes over 250 species, of which only 8 are European. The common blister-beetle or Spanish-fly, *Lytta* or *Cantharis vesicatoria*, is a splendid golden-coloured or bluish-green beetle (occasionally seen in England, as in Essex in 1901), common on many European trees, and devours their leaves. The females lay a large number of eggs in a hole in the ground, whence, after 3 to 4 weeks, the larvæ pass in all probability into certain bees. For medicinal purposes, the beetles are dried and rubbed into powder. The irritant substance is found throughout the body, but especially in the ovaries. (2) *Mylabris* is a rarer European genus, but includes even more tropical forms than *Lytta*, restricted, however, to the Old World. (3) *Cercocoma*, with 9-jointed feelers, is commoner in Europe; *C. schafferi* is indeed frequent. (4) *Meloe* is a large wingless genus, with about 70 species, represented everywhere except in Australia. The females have a very broad abdomen. They live in grass. On irritation, they allow an oily, yellow, blistering fluid to ooze out from between the joints. The common Oil-beetle (*M. pro-scarabæus*) and another beautiful species (*M. variegatus*) are striking illustrations of romantic life-histories. For this and other particulars in regard to *Meloe*, see article under that head. Apart from their medicinal use, the physiology and life-history of these blister-beetles invest them with very considerable biological interest. The common blister-beetle, Spanish-fly or *Cantharis*, will be further treated at CANTHARIS; and see below.

Blisters are medicinal agents which, when applied to the skin, raise the cuticle into vesicles filled with serous fluid. They are applied either in the form of plasters or in a fluid state, as suits the convenience of the person or part, and have for their object the establishing of a counter-irritation or diversion of inflammatory action from a part in which it cannot be reached by remedies, or from some organ where it may do permanent mischief, to some more superficial part of the body.

The most common blister in use is made of *Cantharides* or Spanish fly (*Cantharis vesicatoria*). *Cantharides*, mixed with a convenient proportion of lard and wax, form the blistering ointment in

ordinary use; the only objection to this preparation being, that if applied too freely, it produces much irritation of the kidneys and urinary bladder. A more convenient application is found in blisteing fluid, which is simply painted on the part; or in the prepared plaster, which is cut to the desired shape and size and fixed to the part with a bandage. But under no circumstances should a blister be left long upon children, as it may produce sores which are difficult to heal.

Mustard (*Sinaps nigra*) is frequently used to redden the skin, but seldom left on sufficiently long to produce blistering. Tincture of cantharides, croton-oil, strong liquor ammoniæ, tartar emetic ointment, and many other drugs are used in practice.

If the occasion for the blister passes off, the vesicles should be pricked, and their fluid contents allowed to trickle away, the vesicated surface being then dressed with oil or vaseline. But if it should appear desirable to promote a discharge from the skin, the raised cuticle may be snipped off, and some stimulating application such as savine ointment (*Juniperus sabina*) used to dress the raw surface. Great cleanliness should be observed in dressing the part.

Blisters are used for the relief of acute inflammation in internal organs—e.g. the pleura, lungs, membranes of the brain; for the dispersion of the products left by inflammation—e.g. in indolent ulcers of the skin, enlarged lymphatic glands, pleural effusions, ovarian inflammation, and chronically inflamed joints; and for the relief of pain, even where no inflammation is present—e.g. in many forms of neuralgia. To name all the conditions where blisters may be of use would mean a very long list of diseases.

Blister is also one of the names applied to a bleb on the skin filled with fluid, by whatever cause produced—friction, disease, &c., as well as by vesicants, or other medicinal agents. See BULLÆ.

Blizzard is a fierce storm of bitter frosty wind with fine blinding snow, in which, especially in the western states of the American union, man and beast often perish. In one which visited Dakota and the states of Montana, Minnesota, Nebraska, Kansas, and Texas, in January 1888, the thermometer fell within twenty-four hours from 74° above zero to 28° below it in some places, and in Dakota went down to 40° below zero. In fine clear weather, with little or no warning the sky darkened and was filled by snow or ice-dust as fine as flour, driven before a wind so furious and roaring, that men's voices were inaudible at a distance of 6 feet. Objects became invisible a few yards off. Farmers died in the fields ere they could reach their houses, and children on their way from school; some of those who died having been not frozen but suffocated, from the impossibility of breathing the blizzard. Some 235 persons lost their lives. This was the worst since 1864; the Colorado River in Texas was frozen with ice a foot thick for the first time in the memory of man. In some districts blizzards are looked for three or four times in a winter; but really disastrous ones are rare, those of 1836, of December 1863, January 1866, January 1873 being, till that of 1888, the severest on record. The word, which seems to be akin to *blast*, *bluster*, first became usual throughout the United States during the severe winter of 1880-81, but was in colloquial use in the West early in the century. See WIND and STORMS.

Bloch, MARCUS ELIESER, a celebrated ichthyologist, born of poor Jewish parents at Anspach, in Bavaria, in 1723. He settled in medical practice at Berlin, where his life was uneventful, and where

he died, August 6, 1799. He is chiefly remembered for his great work, the *Allgemeine Naturgeschichte der Fische* (12 vols. Berlin, 1782-95, with 432 coloured plates), long the most comprehensive work on ichthyology, and still valuable, especially for its illustrations.

Block, in the rigging of a ship, is an important part of the apparatus necessary for raising sails and yards, tightening ropes, &c. The block comprises both the frame or shell, and the pulley or pulleys—usually termed 'sheaves'—contained within it. In nautical and mechanical language a *tackle* includes the rope as well as the block through which it works. Ships' blocks vary greatly in size, shape, power, designation, and use, but nearly every block comprises a shell or wooden exterior, a *sheave* or wheel on which the rope runs, a *pin* or axle on which the sheave turns, and a *strap* (of rope or iron) to fasten the block to any particular station.

For very many years, the uniform practice was to bind the shells by straps of rope—hempen or wire—but in more recent times, only the smaller class of blocks are thus bound, and those of a heavy calibre are environed by a band of iron—sometimes inside the shell, and said to be 'inside ironbound,' and sometimes outside, when they are termed 'outside ironbound.' Ironbound blocks have been in use in merchant-ships for a much longer period than in government vessels, on board which modern improvements are often slow of being adopted. A single block contains only one sheave, a double block, two; a treble block, three; and so on;

a, single 'outside ironbound' block;
b, double 'inside ironbound' block
(with swivel hooks).

while the term 'purchase-block' is generally applied to all blocks having more than two sheaves. All the blocks on board ship have distinctive names—e.g. *cat-block*, *cheek-block*, *clew-garnet-block*, *clew-line-block*, *boat-block*, *snatch-block*, &c., according to the kind of service they have to perform, or to their place of fixing, while not a few names are examples of the odd and sometimes unaccountable nomenclature adopted by seamen.

Ships' blocks are usually made of elm, and the sheaves of lignum-vitæ, the hardest kind of wood procurable in any considerable quantity. The pins are of iron or steel, and the bushes or bearing parts of the sheave are usually of brass. Patent roller bushes, which allow the sheave to turn with minimum of friction, have for several years been largely adopted. The figures show examples of the blocks most commonly in use.

Blocks made wholly of iron (see PULLEY) are used to some extent about the decks of ships, but are ill adapted for use in ships' rigging, on account of the chafing and fraying of ropes and sails thereby entailed.

Until near the end of the 18th century blocks were all made by hand, and the trade was of considerable importance. For one of the old seventy-fours of the navy alone, more than 1400 blocks were required, and for vessels of larger or smaller size a proportionate number. The introduction of steam in place of the 'unbought wind' as a propulsive power, has materially reduced the number of blocks required on board ship, and the adoption of specialised labour-saving machinery has rendered

their manufacture at the present time a matter of great ease and simplicity. Two men, comparatively unskilled, with the aid of the machines now in use, can produce as many complete blocks in one day as would have taxed the efforts of the skilled artificers of other days during the best part of a week. In 1781 a Mr Taylor began to make the sheaves and shells of blocks by a process which he had invented. He made all the blocks for the royal navy until the expiration of his patent rights. The Admiralty then commenced the manufacture on their own account. In 1801 Mr (afterwards Sir) Marc Isambard Brunel submitted to the Admiralty plans of a system of machinery for block-making, which was accepted, and the inventor engaged to set up the apparatus at Portsmouth. In 1808 the system was put into effective operation, it being found even then so perfect, that very few additions or improvements have since been needed. The machinery made blocks more accurately than they had ever been made by hand, and with the aid of ordinary workmen only. It could effect £50,000 worth of work in a year, or 140,000 blocks, by the assistance of ten men in attendance. Duplicate machinery was made for Chatham. Brunel received £20,000 for his invention and for his personal superintendence until the machinery was brought into working order; this sum was money well laid out, for the system saved to the country more than £20,000 a year, in the busy warlike period from 1808 to 1815.

Block, MAURICE (1816-1900), born at Beilin of Jewish family, studied at Bonn and Giessen, but settled at Paris, where he held a post in the statistical bureau (1852-62). He published many works on the statistics of France and Europe, including the *Annuaire de l'Économie Politique et de statistique*.

Blockade, in a military sense, is an operation for capturing an enemy's town or fortress, often without a bombardment or regular siege. The attacking party throws up works on the neighbouring heights and roads, so as to guard every exit from the town, and the place is now said to be 'invested.' The rest of the besieging force remains under cover in villages, or in a temporary camp, ready to repel any sortie attempted by the besieged. The whole purpose in view is to prevent the besieged from receiving supplies of any kind, in order that, when the food or the ammunition is exhausted, they may be compelled to surrender. Fortresses situated on steep and rocky eminences, difficult to conquer by bombardment or assault, may often be reduced by blockade; because the roads or paths for the reception of supplies are few, and can be watched by a small number of troops. Towns situated on a plain are less easily invested; but if the inhabitants are numerous and commercial, they will soon be impatient of the restraint produced by a blockade, and compel the governor to surrender. When, therefore, resistance is determined on, the governor sends out of the town as many non-combatants as possible. He then collects all the stores in bomb-proofs, places the inhabitants on an allowance of food and under military rule, and endeavours, by frequent sorties, to prevent the besiegers from completing the investment of the place. A blockade should be the first step in a regular siege, and its effects may often be made more quickly felt by a bombardment. The blockade of Paris by the Germans in 1870-71 is the most notable example of such an operation that has ever been known. It was of itself completely successful in four months. In this case a large civil population was blockaded together with a numerous army; but at Metz, in the same campaign, a large and well-appointed army, compara-

tively unhampered by the civil population, was compelled to surrender by a blockade without bombardment in less than three months (see also SIEGE). In 1877 Plevna was reduced by blockade, after Russia and Rumania had assaulted unsuccessfully three times. In the Great War there was no blockade proper on land.

Blockading, in a naval sense, is the prevention of the entrance or exit of the enemy's ships at a particular port, or at all the ports on a stretch of coast, so as to bring pressure to bear upon the inhabitants by obstructing their trade; and it renders intercourse with the enemy's ports unlawful on the part of neutrals. It is also sometimes an auxiliary to the military blockade by land. For a valid blockade it is necessary that a state of war should exist; that the blockade be really effective, that is to say, it must be maintained by a force sufficient to prevent access to the enemy's port, or at least to render approach hazardous; and neutral nations must be informed by the blockading power, either by official notification to all those powers, or by warning given to neutral vessels which approach the line of blockade. But when a blockade has become notorious, the knowledge will be presumed against any merchant-vessel which attempts to enter the blockaded port. Effective blockade is the principle laid down in the Declaration of Paris (1856), but this is construed more rigidly by continental nations than by England or the United States. Riga was effectively blockaded during the Crimean war at a distance of 120 miles. The French insist more than we do on formal notice. The blockading force may seize any vessel with its cargo trying to trade with the port, and send it home for condemnation; and if the vessel succeed in breaking the blockade, it may be pursued and captured by a belligerent, until it has reached its port of destination. That breach of blockade involves confiscation of the ship is admitted by all civilised nations. The cargo is not forfeited unless its owner is the owner of the ship, or was cognisant of the intended violation.

Napoleon's Berlin decree of 1806 declared the British Islands in a state of blockade (see CONTINENTAL SYSTEM).

A memorable blockade was that of the ports of the Southern States by the Federal government during the American civil war. The blockade was begun in April 1861, and, extending as it did to the whole of the southern coast and ports, was at first somewhat ineffective. Ultimately it was more rigorous and systematic; but to the last a considerable trade was carried on by swift steamers. During the Great War, 1914-18, Germany was blockaded, and the effectiveness of the blockade contributed largely to the winning of the war by the Allies. The approaches to Germany were blockaded by the Dover Patrol and 10th Cruiser Squadron of 24 armed mercantile cruisers, with 18 trawlers operating between Iceland and the Shetlands and Hebrides. In two years this squadron intercepted and examined 15,000 vessels, and only 4 per cent. of the vessels attempting to get through were not examined, in spite of blizzards, fog, dark nights, &c. The Grand Fleet, stationed partly at Rosyth and partly at Scapa, prevented the blockading vessels from being molested excepting by submarines.

See CHARLESTON, NEUTRALITY, PRIZE; and as to the law, books by Twiss, Hall, Phillimore, Hazlitt, Roche, T. Laurence, Halleck for England; Wheaton for the United States; Hautefeuille, Heffter, Gessner, and Bluntschli for the continent of Europe; the collections of treaties; and the proceedings of the *Alabama* Commission. Lord Stowell's decisions in the prize court during

the French wars may be said to form the substance of English law on this subject.

Blockhouse is a bullet-proof building of any material, roofed in and loopholed, often made with the floor sunk 4 or 5 feet. If timber alone is used, it must be 3 feet thick to resist modern rifle-bullets. Better material is sheeting of wood or corrugated iron, with 6 inches of stones or 12 of earth between. The buildings are not proof against artillery attack, and it is difficult, but not impossible, to render them inconspicuous. They are particularly useful in savage warfare, in mountain and forest country, as well as for the use of posts guarding bridges on a line of communications from raids, and as keeps on the rear faces of redoubts for a final stand. In this case they must be very solidly roofed, and kept low and inconspicuous. In the Great War they were often made of very solid reinforced concrete, proof against all but the heaviest shells; the concussion, however, of a direct hit would sometimes kill the whole garrison, without a break-through. A blockhouse may be of any size and shape, and forms a barrack for its garrison. If large it is generally cruciform in plan, so as to gain flank defence, or the upper story may project over the lower to enable men to fire through loopholes in the floor. The same object is sometimes attained by placing the upper story diagonally across the lower one. A ditch is excavated round the blockhouse to prevent the enemy getting close enough to set it on fire or to use the loopholes. Stakes are planted in the ditch to make it difficult for the enemy to collect in it, and there rally for the final assault. In the later guerilla stages of the Transvaal (q.v.) war (1901-2) extensive use was made of a series of blockhouses by Lord Kitchener. Nearly 5000 of them were built, from 2000 to 3000 yards apart, totally enclosing a very large extent of country. They were constructed of sheets of corrugated iron 4 inches apart, filled in with stone ballast, and surrounded and connected by barbed wire.

Block Island, 9 miles S. of Rhode Island, U.S., is 8 miles long, and contains the township of New Shoreham, a summer-resort.

Block-printing, the method of printing, or producing *Block-books*, from wooden blocks. See BIBLIA PAUPERUM, WOOD-ENGRAVING, PRINTING.

Block-system. See RAILWAYS.

Bloemfontein, the capital of the Orange Free State, in the South African Union as in the days of the republic, stands in a high (4450 feet) and healthy district, between the rivers Modder and Riet, 200 miles W. by N. of Durban. It is connected by railway with the Cape and, since 1890, with Johannesburg and Natal. It is the seat of the South African Supreme Court, of an Anglican bishopric, and of Grey University College and other colleges, and has a good deal of trade, mainly in wool. Bloemfontein was occupied by Roberts (May 1900), and here the Orange Free State was proclaimed a British colony. Pop. 36,000, nearly one-half white.

Blois, the capital of the French department Loir-et-Cher, has a remarkably fine situation on a steep acclivity, and is built chiefly on the right bank of the Loire. The old town, with its crooked, narrow streets, is mainly on the hill, crowned by the historic castle; the new business town, with fine quays, is near the river. An eleven-arch bridge (1717), 1000 feet long, unites the town with its suburb of Vienne on the left bank. It is 36 miles SW. of Orleans. Blois has a cathedral; but its chief glory is its old castle, which has been the scene of many interesting historical events. Louis XII. was born in it; and under its roof Charles, Duc d'Alençon, and Margaret of Anjou were married. Here also the Duc de Guise and his brother, the

cardinal, were murdered, by order of Henri III., 23d December 1588. Isabella, queen of Charles VI., here found a retreat; it served as a prison for Mary de' Medici; Catherine de' Medici died within its walls; and Maria Louisa here held her court in 1814, after Paris had capitulated. The castle was then neglected and used as a barrack; since 1845, but especially in 1880-87, a great part of it has been finely restored at great cost. Blois is a place of great antiquity. Stephen, who usurped the crown of England on the death of Henry I., was a son of one of the counts of Blois, by Adela, the daughter of William the Conqueror. Other celebrated natives have been Peter of Blois, subsequently archdeacon of London, and author, who died in 1200; and Denis Papin (q.v.), to whom a statue has been erected. Blois is an archbishop's see, and has manufactures of porcelain and gloves, with a trade in brandy, wine, and wood. Pop. 24,000.

Blomefield, FRANCIS, the topographer of Norfolk, rector of Hargham and Fersfield, and afterwards of Brockdish, was born at Fersfield, 23d July 1705, and died 16th January 1752. The great achievement of his life was his *History of Norfolk*, which, though abounding in errors, is a vast storehouse of information on the subject. In 1735, while collecting materials for it, he discovered the 'Paston Letters.' The first volume appeared in folio in 1739, the second in folio and quarto in 1745; Blomefield died ere the completion of the third volume, which, with a fourth and fifth, by the Rev. C. Parkin, appeared at Lynn (1769-73; new ed. 11 vols. London, 1805-10; index, 1862).

Blomfield, CHARLES JAMES, Bishop of London, was born in 1786 at Bury St Edmunds, in Suffolk, where his father was schoolmaster. Thence he passed to Trinity College, Cambridge, of which he was elected a fellow; and taking orders in 1810, he became incumbent of St Botolph, London (1819), Archdeacon of Colchester (1822), and Bishop of Chester (1824), whence in 1828 he was translated to London. Blomfield's reputation for classical scholarship rests on his editions of Æschylus, Callimachus, Euripides, &c. He was exceedingly active in the superintendence of his diocese, and was an originator of the movement for the erection of new churches, setting about the building of fifty at once. He died 5th August 1857. See the Life by his son (2 vols. 1863).

Blommaert, PHILIP, a Flemish author, with Conscience a reviver of the Flemish tongue, born at Ghent in 1809. In 1834 he published a volume of verse; but he rendered better service to literature and to the patriotic cause by his editions of *Theophilus* (1836), an old Flemish poem of the 14th century, and of the *Oudvlaemsche Gedachten* (3 vols. 1838-51) of the 12th, 13th, and 14th centuries. His most important work is a history of the Belgians (1849), in which he shows that the Low Countries, spite of political separation, have a unity of culture, and that the political welfare of Belgium is opposed to a French alliance. He died at Ghent, August 14, 1871.

Blondel, a celebrated French minstrel of the 12th century, born at Nesle, in Picardy, was a favourite of King Richard the Lion-heart, and accompanied him to Palestine. When, in 1193, Richard on his homeward journey was seized and imprisoned by Leopold, Duke of Austria, the minstrel wandered through Germany in disguise seeking his master, and at length came to the castle of Dürrenstein, in Austria, in which he heard that there was some illustrious captive. He placed himself under the tower and commenced singing a love-song which Richard and he had composed together. Hardly had he finished the first stanza,

when a well-known voice from the tower took up the second, and carried it on to the end. So the minstrel discovered his monarch, and, returning with all speed to England, was the means of his being ransomed by his subjects. Unfortunately, this story rests solely on the French Chronicle of Rheims, belonging to the latter half of the 13th century; its popularity dates only from Grétry's opera (1784). The poems that have come down to us under Blondel's name are poor and uninteresting; they were published by Tarbé in the *Collection des Poètes Champenois* (vol. xix. Rheims, 1862).

Blondin, CHARLES, rope-dancer, born 24th February 1824, at St Omer near Calais, his real name being Jean François Gravelet. In 1859-60 he four times crossed the Niagara Falls on a tight-rope, once blindfolded, once trundling a wheelbarrow, once carrying a man on his back. He also performed in London, and he died in Ealing in 1897.

Blondlot Rays, thought by Professor Blondlot of Nancy (1903) to be given off by almost all substances (human nerve and muscle as well as steel bars) when in a state of strain, and by him called N-rays, were never verified by English or German experimenters, and by 1907 were given up by everybody. Becquerel had verified Blondlot's observations, the discoverer received a gold medal from the Academy, and in 1903-6 no less than 176 papers were published on the (non-existent) rays.

Blood is the red-coloured fluid found in the heart and blood-vessels. Its amount is from $\frac{1}{4}$ to $\frac{1}{2}$ of the body by weight. It is an opaque, sticky fluid with a specific gravity of about 1055, an alkaline reaction, an aromatic odour, and a saline taste. Its colour varies with its condition as regards oxidation. Blood which has come from an artery or been exposed to the air is bright red, while venous blood is much darker and almost purple in colour. When a drop of blood is looked at under the microscope it is seen to consist of a number of formed elements floating in a clear straw-coloured fluid, the *plasma* or *liquor sanguinis*.

The formed elements are the red blood corpuscles or erythrocytes, the white cells or leucocytes, the blood plates, and granular material known as *haemocoina* or blood dust.

The *red corpuscles* in the mammals, with the exception of the camelidae which have elliptical corpuscles, are bi-concave discs. They have an interesting life-history. In the young embryo all the red corpuscles are much larger than those found in post-natal life. They have a large nucleus showing an open chromatin network, and are known as megaloblasts. In later fetal life these cells are replaced by others not so large with a nucleus which is much denser. These are known as normoblasts. In mammalia, except in early embryonic life, the nucleus undergoes a process of digestion and absorption before the corpuscle is passed into the circulating blood, and it is only in conditions of disease that nucleated red cells are found in the blood-vessels. They remain numerous, however, in the red bone-marrow found in the flat bones and at the ends of the long bones, as it is in these situations that the red corpuscles of the blood are developed. In the lower vertebrates—birds, reptiles, amphibians, and fishes—the red cells are oval and the nucleus persists throughout the life of the corpuscle. The size of the blood corpuscle varies considerably in different animals. In man its diameter is .0075 millimetre or $\frac{1}{3200}$ inch. The corpuscles when seen singly are pale yellow. It is only when they are massed together that they appear red. When blood is shed the red corpuscles tend to run together and adhere in long columns like piles of coins or *rouleaux*. The erythrocytes are very easily affected by changes in the salt con-

tent of their surroundings. If the fluid surrounding them becomes concentrated by evaporation or by the addition of salt the corpuscles become jagged and irregular in outline, and are then said to be *crenated*. If, on the other hand, the plasma be diluted with water the corpuscles swell up, and if the dilution passes a certain point they rupture and the greater part of their contents passes into solution. The blood then becomes transparent, and is said to be *laked*. The corpuscles are soft and elastic, and are surrounded by a fine elastic membrane. Inside this membrane is a loose delicate stroma which supports a red pigment known as haemoglobin. The base most abundantly present is potassium. Lecithin and cholesterol appear to enter largely into the composition of the membrane and stroma. The haemoglobin constitutes 90 per cent. of the solid matter of the corpuscles. It is closely allied to the proteins, but contains .42 per cent. of iron. It is readily oxidised, and in combination with gases gives characteristic absorption bands when examined with the spectroscope. The red corpuscles number 5,000,000 per c.mm. in the adult male, and 4,500,000 per c.mm. in the female. Their numbers may be greatly diminished in disease, and in the severe anæmias nucleated red corpuscles may escape from the bone-marrow into the circulating blood.

The *leucocytes* or white cells are spherical in shape. Several varieties have to be distinguished. The most numerous is the *neutrophil* leucocyte, which has a lobulated nucleus and shows granules with a special affinity for a mixture of acid and basic dyes in its protoplasm. This cell is considerably larger than the red corpuscle. It constitutes about 70 per cent. of the white cells. Its numbers are increased in the circulation in most of the ordinary infectious diseases. The *eosinophil* leucocyte has larger granules which have a special affinity for the aniline dye known as eosine. It should not exceed 4 per cent. of the leucocytes in health, but in many infections with animal parasites and some other conditions its numbers are much greater. The *lymphocyte* has a rounded nucleus. It varies in size from that of the red corpuscles to three times their size. It tends to increase in chronic infections such as tuberculosis. In health its percentage of the white cells is about 25. All varieties have the power of throwing out processes and changing their shape and position. This is known as amoeboid movement, since it is similar to that seen in the simple organism, *Amoeba* (q.v.). They have also the power of ingesting micro-organisms or other foreign particles with which they may come in contact (see PHAGOCYTES). The leucocytes number about 7000 per c.mm. Their numbers are increased in the blood during digestion, in pregnancy, and in a great variety of pathological conditions as indicated above. The granular leucocytes are developed from cells in the red bone-marrow, known as myelocytes. The lymphocytes are also derived from bone-marrow as well as from various lymphoid tissues throughout the body.

a, Large nucleated red cell of the early embryo; b, nucleated red cell of bone-marrow; c, ordinary red blood corpuscle; d, the same in profile; e, neutrophil; f, eosinophil; leucocyte; g, large, h, small, lymphocyte. From human blood magnified 1000 times.

The *blood plates* are colourless refractile discoid bodies less than half the size of a red corpuscle. They seem to play an important part in connection with the process of clotting of the blood. Otherwise their origin and significance are unknown.

Hæmocœnia consist of small colourless granules. The term 'blood dust' probably suggests their significance.

The *blood plasma* is usually clear and transparent, but after a fatty diet it may appear milky. It contains serum albumen and serum globulin. A globulin of special importance is known as fibrinogen. It also contains sugar, fats, and waste products, such as urea derived from the tissues. The most abundant of the inorganic constituents are salts of soda, but there are also small amounts of calcium, potassium, and magnesium. The yellow colour is due to the presence of a fatty pigment or lipochrome.

Coagulation of the Blood.—After blood has been withdrawn from the vessels it forms a jelly-like mass. This change occurs in about ten minutes. If this clot is now left undisturbed a clear yellow fluid begins to exude from it and the clot diminishes in size, so that after a few hours it will be found to have retracted from the walls of the containing-vessel and to be surrounded by the fluid which has exuded. This fluid is known as *serum*. Serum on analysis is found to be the same as plasma, except that it contains no fibrinogen. If a portion of the clot be washed in running water, it is found to consist of stringy elastic whitish threads which have entangled the blood corpuscles. The stringy material is called fibrin. Coagulation therefore consists of the transformation of the soluble globulin, fibrinogen, into the insoluble fibrin. If blood as it is shed be beaten up with a stick the fibrin adheres to the stick, and the corpuscles, instead of becoming entangled in the fibrin, remain in the serum. The resulting serum and corpuscles is called defibrinated blood. Clotting is hastened by heating the blood. It is delayed by cooling the blood and by the addition of strong solutions of salts. When clotting is prevented and blood allowed to stand, a sediment of corpuscles falls to the bottom, leaving above a clear layer of plasma. The heavier red corpuscles fall to the foot; the lighter white cells form a layer above. The chemistry of coagulation is very elaborate. It appears to be due to the action of a ferment, the fibrin ferment or thrombin. This ferment seems to be evolved by the union of an antecedent substance, prothrombin, which is present in the leucocytes, with salts of lime. But the union does not appear to take place spontaneously, but only after the addition of a tissue extract, such as may come from the edges of a wound.

Functions of the Blood.—The blood plays an essential part in connection with the nutrition of the body. The plasma carries the nutrient material absorbed from the food to the tissues, and conveys the waste products of tissue activity to the excretory organs. The carbon dioxide formed by the tissues combines with the soda, and when the lungs are reached it leaves the soda and passes into the atmosphere. The red corpuscles are the carriers of oxygen from the lungs to the tissues. The leucocytes act as distributors of food, and play an important part in the defence of the body against infectious disease. Coagulation of the blood is a provision to protect the body from hæmorrhage. The blood is also the carrier of chemical messengers or hormones which are produced by one organ and effect the activity of another organ at a distance. See RESPIRATION, ARTERIES, CIRCULATION, VEINS; also ANTISEPTIC SURGERY, BACTERIA, BLEEDING, BLOOD-STAINS, GERM (for the germ theory of disease), INOCULATION, MALARIA, PHAGOCYTES,

PYÆMIA, TRANSFUSION, WOUNDS; further, ANIMAL HEAT, TEMPERATURE.

Of old it was reckoned the duty of the next of kin to avenge a murdered relative; but among some primitive peoples, as the modern Bedawins, the right is annulled by compensation. The Mosac law prohibited the commutation of the penalty of death for money, and appointed *cities of refuge* for the involuntary manslayer. See CITY OF REFUGE, SANCTUARY, BLOOD-WITE, WERGILD. For the blood-fend, see VENDETTA. The eating of blood was prohibited by the Old Testament. Christians have generally regarded the prohibition as having ceased with the reason for it, and consider the exhortation of the apostolic council of Jerusalem to the Gentile converts, to abstain 'from things strangled and from blood,' to have been merely an application of the great law of Christian charity to the circumstances of a transition period, with reference to the prejudices of Jewish converts. Jews still always kill their own butcher-meat, and Mahomedans observe similar rules. Among some primitive peoples the bond of blood-brotherhood is established between friends by ceremonial mixing and drinking of their blood. See also SACRIFICE, LORD'S SUPPER, TRANSUBSTANTIATION.

Blood, THOMAS, adventurer, was born in Ireland about 1618, and in the Great Rebellion sided with the parliament. Deprived of his estate at the Restoration, he put himself in 1663 at the head of a plot to seize Dublin Castle and Ormonde, the lord-lieutenant. On its discovery his chief accomplices were seized, and executed; but he himself escaped to Holland, and was there received with high consideration. He soon found his way back to England to try what mischief might be brewed among the Fifth-Monarchy men; and thence proceeding to Scotland was present at the battle of Rullion Green (1666). On the night of 6th December 1670, the Duke of Ormonde was seized in his coach in St James's Street by a gang of braves, tied on horseback behind one of them, and hurried away towards Tyburn. The timely approach of his attendants at the moment when, in struggling with his riding-companion, he had succeeded in bringing him to the ground, probably saved the duke from hanging. Blood was the leader in this daring villainy. His next enterprise was still wilder and more dangerous. On 9th May 1671, disguised as a clergyman, with three accomplices he entered the Tower, determined to carry off the regalia. After nearly murdering the keeper of the jewels, he actually succeeded in getting off with the crown under his cloak, while one of his associates bore away the orb. They were pursued, however, seized, and committed to the Tower. Now came a singular turn of fortune. At the instigation of Buckingham, who was accused of having hired Blood to attack the Duke of Ormonde, King Charles visited the dauntless miscreant in prison, and, dreading the threat that there were hundreds of Blood's associates banded together by oath to avenge the death of any of the fraternity, pardoned him, took him to court, restored him his estate of £500 a year, and raised him so high in favour that for several years Colonel Blood was an influential medium of royal patronage. He quarrelled, however, with Buckingham, and was committed by the King's Bench on a charge of slander against him; he was bailed out, but died on 24th August 1680. See T. Seccombe's *Lives of Twelve Bad Men* (1896).

Blood-bird of New South Wales (*Myzomela sanguinolenta*), a species of Honey-eater (q.v.) (Meliphagidæ), so named from the rich scarlet colour of the head, neck, breast, and back of the male. A very similar species is found in Bengal.

Blood-flower (*Hæmanthus*), a genus of *Amarylhidaceæ* (q.v.), mostly natives of South Africa, some of which are common in greenhouses. They take their name from the usual colour of their flowers, which form a fine head or crowded umbel. The bulbs are sometimes propagated by cutting them across above the middle, so as to stop the single growing point; new axillary bulbs then form around the outer edge. The species seem generally to possess poisonous properties. The inspissated juice of *H. toxicarius* is used in South Africa for poisoning arrows.

Bloodhound, a variety of Hound (q.v.), remarkable for its exquisite powers of scent, and for the eagerness with which it tracks a bleeding animal; it is able to select a freshly-wounded deer from among a herd, and follow its trail; and from this faculty it derives its name. It was also formerly called, both in England and Scotland, *s'cut-hound* or *slenth-hound*, from the Middle-English *slenth*, 'a slot or track' (Icel. *sloth*). The bloodhound was formerly common and much in use in Britain, as well as on the continent of Europe for hunting purposes, being in the possession of most noble families, who vied with one another in the purity and excellence of their different strains,

Bloodhound.

but is now rare, though Lord Wolverton, who died in 1887, at one time hunted a pack of bloodhounds in Dorsetshire. Bloodhounds were also much used to track escaped prisoners, and are mentioned in the poetical histories of Bruce and Wallace as being used by their enemies to discover them; and in later days they were resorted to by slave-owners in America in the pursuit of fugitive slaves. The bloodhound is a large tan-coloured dog, with an exceedingly handsome and noble head expressing dignity and strength. The head should be long and narrow, with a dome-shaped skull, the occipital bone forming a peculiar peak on the back of the skull; the eyes distinctly showing the third eyelid or 'haw,' which gives the eye a bloodshot and rather fierce look; the ears long enough to meet in front of the nose, but falling down close on either side of the face; colour, a rich tan with a dark saddle, showing no white if possible. The bloodhound is rather unmanageable when thoroughly roused, on account of his courage and strength, but when properly treated is generally docile, and makes a capital watch-dog. Many interesting anecdotes are recorded of the perseverance and success of bloodhounds in following a track upon which they have been set, even when it has led them through much frequented roads. As recently as 1898-1908 attempts have been made in England to track murderers by means of a bloodhound.—The CUBAN BLOODHOUND, notorious as having been employed

in the pursuit of felons and of fugitive slaves in Cuba and the slave-holding states of the American Union, differs largely from the true bloodhound, and is really the descendant of mastiffs with a bulldog cross, inferior to the real bloodhound in scent and all but ferocity; it is also called the Cuban mastiff. According to Powell (*The American Siberia*, 1892), foxhounds, specially bred and trained, are used for man-hunting in nearly all the convict-camps of Florida, &c. For the true bloodhound's kin, see TALBOT.

Blood-poisoning is a name loosely used of *Pyæmia* (q.v.) and allied diseases (see POISON, WOUNDS). It is also used popularly in a wider sense for the results on the human system of poison germs from malaria, bad drains, &c.; or for the condition of the blood caused by such ailments as Bright's disease of the kidneys. See GERM, HYGIENE, MALARIA, PTOMAINES, TYPHOID FEVER, &c.

Blood-rain, which doubtless has its origin in the up-rushing currents of waterspouts and whirlwinds, has frequently fallen in Italy and southern Europe, and has been repeatedly traced, through the microscope and chemical test, to the sandy deserts of northern Africa adjoining. Similar rains have fallen in the Canaries, and they may be likewise ascribed to the African desert to the eastward. In these cases the origin is the rainless whirlwinds of these arid deserts, which are locally called 'devils.'

Blood-root. See GEUM, HÆMODORACEÆ, and SANGUINARIA.

Blood-stains are often an important means of establishing the guilt of prisoners, especially in murder trials. The methods for distinguishing the kind of blood that gave rise to the stain fall into three groups, of which the newest is the *Serological* or *precipitin* test, which distinguishes human from other mammalian blood. The oldest method was the *Visual*—aided by *a*, ordinary lens; *b*, microscope; *c*, spectroscope; *d*, artificial light. A third method is *Chemical*—*a*, heat—*positive* (1, change of colour; 2, coagulation); *b*, ammonia—*negative*; *c*, hæmatin test; *d*, guaiacum test.

Blood when liquid stains all articles with which it comes in contact. It sinks into woven textures and such material as soft wood, but on metallic surfaces and on hard woods it forms a film of greater or less thickness, and quickly dries. At first it is of a reddish-brown colour, but in the course of a few weeks this deepens and becomes almost black.

Looked at with a lens of low power—say 10 or 20 diameters—the blood, if in any quantity, and coagulated, and if it has not sunk into the texture of the cloth, is observed to present an irregular surface, and entangled in it have frequently been detected foreign materials which have afforded a clue to the culprit, and to the manner in which the crime has been committed. Thus hairs, fragments of cotton, epithelial scales from the throat, and minute fragments of birds' feathers have often been noted. This preliminary investigation concluded, the attempt is now made to discover the peculiar corpuscles of the blood (see BLOOD). This is a matter of great difficulty when the blood has stained such articles as linen or cotton stuffs and become dry, but when spilt on hard surfaces, or when it is in such quantity as to form a distinct coagulum, the corpuscles are generally easily determined by the following process. The object is, by breaking up the coagulum, to dissolve out the corpuscles in some medium as nearly as possible of the same density as the *liquor sanguinis* of the circulation. Numerous media have from time to time been proposed, such as solutions of sugar, phosphate of soda, iodide of potassium, &c., but the one generally employed is a solution of glycerine in

water of specific gravity 1.028. If this solution be applied, for example, to the stained blade of a knife, or if a minute portion of dried blood-clot be gently dissolved in it, a reddish fluid is obtained which under a high power of the microscope (300 diameters) rarely fails to exhibit numerous corpuscles which by their peculiar appearance (see BLOOD) are at once recognised to be mammalian blood-discs. In the case of stained linen, &c., there is greater difficulty. The stained portion must be thoroughly moistened with the solution, and then squeezed over a glass rod. When the reddish fluid reaches the surface, it must be removed with the blade of a knife, placed on glass, and submitted to the microscope. By this simple process, unless the stain be of great age, its character is determined. Human blood in these circumstances, however, cannot be distinguished from the blood of the other members of the great class of the mammalia, with the solitary exception of the camel tribe, which present an oval blood-corpuscle (see CAMEL).

Of late years, the interesting fact has been discovered that blood possesses a distinct spectrum, so that it is possible to determine that a reddish fluid is really blood, although the corpuscles may not have been discovered owing to their accidental destruction. The stained portion of cloth or a portion of blood-clot is digested in distilled water, and as the result a liquid of a reddish colour is obtained. This should be placed in a deep narrow cell and examined by a spectroscopic eye-piece with a low power of the microscope. Two dark bands make their appearance, one in the middle of the green rays, and the other at their junction with the yellow. These are highly characteristic of the presence of the blood of some red-blooded animal. See SPECTRUM, and SPECTROSCOPE.

Lastly, under this head of the visual detection of blood, the presence of blood-stains may unexpectedly be discovered with artificial light, by examining the furniture and especially the walls of an apartment on which blood has fallen. During the day the spots of blood remain undetected, but at night, and with artificial light, they are clearly visible. It is especially on papers with dark-blue figuring that this interesting fact has been observed.

The chemical relations of blood are very definite. All stains due to blood are soluble, and this fact enables us at once to distinguish them from insoluble stains which closely resemble them, and which have frequently been mistaken for them, such as paint and ironmould. The stain to be examined is cut out and suspended by means of thread in a glass tube filled with distilled water. Should the stain be at all recent, it immediately dissolves, and long filmy streaks of colouring matter are discharged and descend in wavy lines to the bottom of the tube, where ultimately a stratum of reddish fluid of greater or less intensity is collected. The clear supernatant fluid is poured off, and the coloured portion is divided into two parts. One part is boiled, and if the fluid contain blood, the following peculiar changes take place. The colour is discharged, the redness disappears and gives way to a grayish green, and in addition a distinct coagulum is formed. Both these changes are highly characteristic of blood. Should some liquor potassæ be now added, the coagulum is redissolved, and shows a green colour by reflected light. This may be described as a positive test of the presence of blood. The action of ammonia supplies us with a valuable negative one. If this volatile alkali be added to a solution of blood, no change of colour is produced. All other soluble stains are more or less altered in colour, such as those from the juices of fruits, &c., which have frequently been mistaken

for blood, and thus have given rise to grave suspicions. If a particle of dried blood can be removed from a weapon or any surface, an attempt may be made to prove that it is blood by the formation of blood or hæmatin crystals. And where it was suspected that articles of clothing had been washed in order to obliterate the traces of blood, its presence has been determined by its reaction with the resin of guaiacum. On the suspected site of the blood-stain are placed a few drops of a spurious solution of guaiacum freshly prepared. The resin is at once observed to separate on the surface of the cloth; if to this is now added a small quantity of peroxide of hydrogen, a beautiful sapphire-blue colour is struck.

The corpuscles of human blood cannot thus be distinguished from those of other mammals (save the camel, which has oval corpuscles). But if human blood is injected several times into any animal (rabbit, dog, sheep, horse), and if afterwards the animal is bled, a clear serum may be prepared, free of corpuscles. If to this serum a drop of human serum is added, it forms a precipitate which falls to the bottom. Even dried human blood can be recognised by this method; if it be dissolved in normal salt solution and placed in a tube containing the serum above described, and if then a precipitate forms, the stain being tested is the stain of human blood (there may be some risk of confounding the blood of apes with human blood). The serological or precipitin test has been made indispensable in Prussia in certain medico-legal inquiries.

See A. S. Taylor, *Principles and Practice of Medical Jurisprudence* (5th ed. 1905); and the manuals of Glaister, Poore, Giffen, McCallin, Husband.

Bloodstone, a dark-green stone spotted with red; see HELIOTROPE. Also a name for red hematite.

Blood-vessels. See AORTA, ARTERIES, BRACHIAL ARTERY, CAPILLARIES, CIRCULATION, VEINS; also such articles as ARTERIOTOMY, THROMBOSIS, VARICOSE VEINS.

Blood-wite (O.E. *blōd-wite*, 'blood-punishment'), in Old English law, a fine paid to the king or ealdorman for the shedding of blood as an offence against the state, as distinguished from the *Weegild* (q.v.), or compensation to the slain man's kin.

Blood-worm, a name given by anglers and others to the very abundant aquatic larva of a gnat-like Dipterous insect known as *Chironomus plumosus*. This is the commonest of a large number (195) of British species, and the larva is very frequent in stagnant water. It has a worm-like appearance, a blood-red colour, and is used for bait. The development of *Chironomus* is of great biological interest on account of the very early isolation of those elements which are to form the future reproductive organs of the insect. Before the cells of the dividing egg have had time to change at all, these future reproductive rudiments are set apart, and as they do not share in the future changes of development, they must obviously preserve intact the constitution of the parent, and hand it on to the next offspring. See HEREDITY.

Bloomer Costume, a ladies' dress partly resembling male attire, which arose out of what is termed the 'Woman's Rights Movement' that began to be agitated in the United States about the year 1848. About the same time, and in close connection with this movement, arose an agitation for the reform of female attire. In 1849 Mrs Bloomer (who died 31st December 1894) adopted the costume to which she has given her name, and lectured on its advantages. The Bloomer dress consisted of a jacket with close sleeves, a skirt falling a little below the knee, and a pair of Turkish trousers. Though a few ladies followed

the example of Mrs Bloomer, the dress was extremely unpopular, and exposed its adherents to a degree of social martyrdom which the more prudent, timid, or amiable declined to brave. Dress reformation societies and private persons have from time to time advocated changes in the costume of women less radical than Mrs Bloomer's, especially a knickerbocker dress for bicycling.

Bloomery, the first forge through which iron passes after it has been melted from the ore, and where it is made into blooms. See IRON AND STEEL.

Bloomfield, ROBERT, the author of *The Farmer's Boy* and other pastoral pieces, born 3d December 1766, at Honington, near Bury St Edmunds, was the son of a poor tailor, who died when Robert was a year old, leaving his wife to struggle with a school, where the future poet learned to read. At the age of eleven he was hired to a farmer, but ultimately became a shoemaker in London, where he wrote his *Farmer's Boy* in a poor garret. Through the efforts of Capel Loftt it was published in 1800, had extraordinary popularity, and was translated into a number of languages. He subsequently published *Rural Tales*, *Wild Flowers*, and other pieces. The Duke of Grafton interested himself in his behalf and gave him a small allowance. He made Æolian harps, wrote poetry, and embarked in the book-trade, but failed. Latterly his health broke down, he became hypochondriac and half blind, and he died in poverty at Sheffield, in Beds, 19th August 1823. A complete edition of his works appeared in 1824, and there were editions in 1864 and 1883. See Darlington's introduction to *The Farmer's Boy* (1898).

Bloomington, capital of M'Lean county, Illinois, 126 miles SSW. of Chicago, is an important railway centre, and has a busk trade and large railway-works, with foundries, furnaces, and coal-mines. There is a Wesleyan university in the town; and near it (at Normal) is the Illinois Normal University, in connection with which there is a state laboratory of natural history. Bloomington has a court-house built of Illinois marble, a Roman Catholic academy, and the Major College for women. Pop. (1860) 7075; (1920) 28,725.—There is another Bloomington, a city lying between the branches of the White River, 60 miles SSW of Indianapolis, in Indiana, seat of the Indiana University. Pop. 11,600.

Blonet, PAUL, better known as 'Max O'Rell,' satirist and lecturer, was born in Brittany 8th March 1848, and educated in Paris. As a cavalry officer he was wounded in the Franco-German war (1870), and coming to England as a newspaper correspondent in 1872, he taught French at St Paul's School, 1876-84, and was editor of the *Paris Figaro* from 1901 till his death, 25th May 1903. Among his witty and satirical books are *John Bull and his Island* (1883); *John Bull's Womankind* (1884); *The Dear Neighbours* (1885); *Friend Macdonald* (1887); *Jonathan and his Continent* (1889); *Jacques Bonhomme* (1890); *Her Royal Highness Woman* (1901).

Blount, CHARLES (1654-93), a London deist, wrote *Anima Mundi*, a translation of *Apollonius Tymanus*, *Great is Diana of the Ephesians*, *Janus Scientiarum*, and a *Vindication of Learning*.

Blount, THOMAS (1618-79), a Herefordshire county gentleman and zealous Catholic, wrote over a dozen works, the best known being *Ancient Tenures of Land and Jocular Customs of some Manors* (1679; new ed. 1815).

Blouse, the French name for a loose, sacklike over-garment somewhat answering to the English smock-frock. France is pre-eminently the country of blouses, ordinarily blue, worn not only by the country-people, but by workmen in towns.

Blow, JOHN, composer, born about 1648, became organist of Westminster Abbey in 1669, and of the Chapel Royal in 1676. For the stage he wrote a masque, *Venus and Adonis*, in which Mary Davis sang the part of Venus before Charles II.; and he was author of many birthday, New Year, and St Cecilia odes, about one hundred anthems, and fourteen services. His contemporaries thought him the 'greatest master in the world' in organ playing, and unprejudiced critics now consider his music in many respects in advance of his age, and as displaying great power and individuality. He died 1st October 1708.

Blow-fly, or FLESH-FLY (*Sarcophaga carnaria*), an insect of the order Diptera ('two-winged'), (q.v.), and of the large family Muscidae, of which the common House-fly, Blue-bottle (q.v.), &c. are familiar examples. It is very similar to these in general appearance; the body is hairy, the expanse of its wings about one inch, the face silky and yellow, the palps black, the thorax gray with three black stripes, the abdomen of a shining blackish brown, which, in

Blow-fly.

certain points of view, assumes a bluish tint, chequered with glittering yellowish spots. One of the distinguishing characters of the genus is, that the eyes are widely separate in both sexes, but in colour, hairiness, and shape of abdomen the males and females differ slightly. The multiplication is as usual rapid (one female may produce 20,000 larvae); some species produce their young alive (viviparously); the larvae feed (as the generic name suggests—Gr. *sarx*, 'flesh,' *phagō*, 'I eat') on the flesh of living or dead animals; the insect passes the winter in the pupa stage. The adults are common in Britain on heaths, in gardens, copses, &c.; and the larvae are to be found feeding upon meat, the carcasses of animals, sometimes upon living earthworms, and too frequently upon sheep, of which it is one of the most grievous pests, requiring the constant attention of the shepherd during most of the summer and autumn. Some districts are more infested with it than others; it is particularly troublesome in the fenlands of England. Unless the maggots are removed, they eat into the skin, the sheep suffer great torment, and soon die. At first they may be removed by shaking them out of the wool, into which dry sand is then abundantly sprinkled; but if they are very numerous, a mercurial ointment or wash of corrosive sublimate is applied; and when the skin is much broken, the wool is clipped away, an ointment of tar and grease is used, and a cloth sewed over the part.

Another of the numerous species of this genus, common in Britain, is *S. mortuorum*, so named from its frequenting burial-vaults and laying its ova on corpses. It is very similar to the blow-fly, but the abdomen is of a shining steel blue, and the palps, feelers, and head are reddish brown. There

are altogether about 50 European species of *Sarcophaga*.

Blowing-machines. The earliest blowing-machine was, doubtless, some form of the common bellows, the idea of which is supposed to have been derived from the lungs. A very primitive form of this instrument is still in use in some Eastern countries, consisting simply of the skin of some animal sewed into a rude bag with a valve and nozzle.

Bellows.—The domestic bellows are worked by drawing the boards apart, when air is sucked in by the valve, to replace the vacuum which would otherwise be formed; and then, when the boards are being closed, the valve, which only opens inwards, is shut by the compressing of the air; so that the latter, having no other escape, is forced out at the nozzle.

The great fault of the common bellows is, that it gives a succession of puffs, and not a continuous blast. One remedy for this was to use two bellows, so that one was blowing while the other was filling; but it was afterwards found that the double-bellows secured a still more uniform blast. This machine, shown in fig. 1, is merely the common bellows with

Fig. 1.—Section of Double-bellows for a Portable Forge.

a third board of the same shape as the other two placed between them, so as to form two chambers instead of one. The middle board is fixed, and both it and the lower one have valves placed in them opening inward. A weight on the lower board keeps the under chamber filled with air; and when this board is raised by a lever or otherwise, the air which it contains is forced into the upper chamber. The exit-pipe is attached to the latter, and a weight is placed on the upper board sufficiently heavy to press the air out in a continuous stream, the continuity being maintained by the large quantity of air always present in the upper chamber, and the uniform pressure of the weight. Even with the double-bellows, however, the blast is not quite regular.

Bellows made entirely of wood except the nozzle, first made in Germany in the 16th century, are in use in some continental countries, but they are only a modification of the common bellows.

The Chinese have a very simple form of bellows, shown in fig. 2, which is not only interesting in

Fig. 2.—Chinese Bellows.

itself, but also because its action is almost the same as the blowing-engine. It is merely a square chamber of wood, with a close-fitting piston, which, when drawn from the nozzle, opens the valves, *v, v*, to admit air, and when pushed in

the opposite direction, shuts these valves, and forces the air out by the nozzle.

Blowing-engines.—For blast-furnaces and for Bessemer steel converters, blowing-engines of large capacity are required. In the United States, where it is customary to work the blast-furnaces so as to produce a greater output of molten iron per diem than in Great Britain, the quantity of air needed for a full-sized blast-furnace varies from 40,000 to 50,000 cubic feet per minute, and the blowing-engines must be capable of delivering this volume of air against a resistance-pressure as great as 25 lb. per square inch, though in the normal working of the plant the pressure will not exceed 15 lb. per square inch. In Great Britain the air-supply required for a full-sized blast-furnace is about 25,000 cubic feet per minute, and the delivery-pressure is about 8 or 9 lb. per square inch. For Bessemer converters the quantity of air needed per minute is very much less, but a pressure as great as 2½ atmospheres is often necessary.

Originally all blowing-engines were of the reciprocating type and steam driven, but in 1899 large gas-engines began to be built, using blast-furnace and coke oven waste gases for their motive-power, for driving blowing-machines and dynamos for generating electric energy (see *Journal of the Iron and Steel Institute*, 1906); and about 1910 the turbo-blower, driven direct by steam-turbines, was brought into use.

The reciprocating type, in addition to the steam or gas engine cylinders, consists in its simplest form

Fig. 3.—Section of a Blowing-cylinder.

(fig. 3) of an air-cylinder, with suction and delivery valves on each of the two cylinder-covers, and an air-tight piston which reciprocates to and fro in the cylinder, the piston-rod in general being direct coupled to the piston-rod of the steam or gas engine; as a result of the to-and-fro motion of the piston, air is alternately inhaled and expelled at each end. The inlet-valves on the top cover are lettered in the fig. A and B (three sides only of this box), those on the lower cover, D, E, and F, while the outlet-valves on the upper cover are on the fourth side of the box, marked C, and on the lower cover, G. The

valves consist of numerous openings, with leather flaps, which normally lie against the openings, but can be forced off the openings when the air-pressure on the outer face exceeds that on the inner face in the case of the inlet-valves; in the case of the delivery-valves, when the pressure on the cylinder becomes greater than that in the air-main, *M*. If, for example, the piston, *P*, were at the top of its stroke, and began to descend, it tends to cause a vacuum above it, and the inlet-valves *A* and *B* at once open inwards, admitting air from the atmosphere to fill up the space above the piston. Simultaneously the air in the cylinder below the piston is gradually compressed until its pressure rises to that in the blast-main, *M*, whereupon the outlet-valves *G* open, and all the air which originally filled the cylinder below the piston is forced out at the blast-pressure into the main, *M*. The reverse action takes place as the piston, *P*, returns from the bottom to the top of the cylinder, the inlet-valves *D*, *E*, *F* now opening, while the outlet-valves *G* and the inlet valves *A* and *B* at once close, and when the pressure above the piston again reaches that in the main the outlet-valves *C* open. These air-cylinders are of large diameter, and the pistons have a long stroke; for example, to supply four blast-furnaces in recently reconstructed works in the Midlands five Galloway vertical steam-engines were installed, having 90-inch diameter blowing-cylinders and each capable of delivering 20,000–25,000 cubic feet of free air per minute against a pressure of 8 to 9 lb. per square inch. In another recent plant two blowing-engines were installed, each capable of delivering 25,000 cubic feet of free air per minute against a pressure of 8 lb. per square inch, these blowing-engines being operated by three double-acting Korting gas-engines deriving their motive-power from blast-furnace waste gases; in this case a steam-driven blowing-engine was installed as a stand-by in case of temporary failure of any of the rest of the plant.

Turbo-blowers, since their introduction in 1910, have been extensively employed both for blast-furnaces and for Bessemer plant. They have certain distinct advantages over reciprocating blowing-machines: they are simpler in design, and for the same unit of capacity they are lighter in weight, take up less floor-space, and require less massive foundations; they in addition involve less original capital outlay, and are cheaper in maintenance. They deliver the air free from the pulsations, almost inseparable with reciprocating blowers, and their one defect, which proved troublesome when they were first introduced, that the volume of air delivered varied not only with the number of revolutions of the engine, as is the case with the reciprocating type, but also with variations in the pressure on the delivery side, has been got rid of by the employment of a blast-gate (butterfly-valve) in the suction-pipe between the air-governor and the air-compressor. They are usually driven direct by steam-turbines, and can, therefore, run at a very high speed up to nearly 3000 revolutions per minute.

The turbo-blowers built by the British Thomson-Houston Co. can deliver 40,000 cubic feet of free air per minute at a delivery-pressure of 25 lb. per square inch when running at 2740 revolutions per minute; they are coupled direct, through a flexible coupler, to a high-pressure multi-stage Curtis steam-turbine. In another case the three turbo-blowers, each driven by a high-pressure steam-turbine, were capable, when running at 2800 revolutions per minute, of delivering 30,000 cubic feet of free air per minute against a pressure of 8 lb.; the B.H.P. of the steam-turbine being

1280, and the steam consumption 13.9 lb. per B.H.P. hour. It is possible to use a combined set of turbo-blower and turbo-compressor to deliver air at a pressure of 12 lb. per square inch for blast-furnace work, and also air at a pressure of 30 lb. per square inch for Bessemer converters. The blower works when required to deliver air at the higher pressure as a two-stage compressor, and when a lower air-pressure is needed the two stages run parallel, delivering into the same air-main.

As far back as 1904 Gayley showed that considerable economy in coke consumption could be obtained by desiccating the air before it was delivered to the furnace; many plants of various types have been put into operation for this purpose, and though they have in some cases been given up on the ground that the economy obtained was not commensurate with the expense of erecting and running the plant, they have on the whole justified their use, especially since they allow the temperature of the hot blast to the furnace to be raised from the limiting temperature of about 1450° F., possible with natural air, to as high as 1600° F., without causing irregularities in the working of the furnace.

All blowing plant for blast-furnace work should have powerful and efficient governing devices, and the driving mechanism should have a good reserve of working-power to allow for possible drop in steam-pressure in the case of steam-plant, or in the heating value of the waste gases when gas-engines are used.

Fans.—The centrifugal fan is another machine for producing blasts of air. It is employed for such purposes as the melting of cast iron in cupolas in foundries, and for smiths' forge fires, and for forced draught for steam boilers. It is also used for extracting foul air from mines, public buildings, and ships. In the case of coal-mines they are often of very considerable size (see VENTILATION).

A common type of blast fan is shown in fig. 4. It consists of a central drum, *A B*, which is fitted with a series of curved blades revolving within a casing; air enters through holes in the centre of

Fig. 4.—Blast Fan.

each of the sides of the drum, and is finally discharged through the outlet, *C*. A fan with a few simple blades will in ordinary practice prove most efficient, provided that the design of the shape of blades and dimensions of the casing have been properly arranged for the class of work the fan has to do. The number of blades varies in different types of fans, which run at speeds varying from 700 to 1800 revolutions per minute. They are often, especially in the case of fans for ventilating buildings, driven direct by electric motors. Such fans are small in diameter, seldom exceeding 3 feet, and the pressure of the fan-blast is small, only a few inches of water; this compression alone enables the fan to do useful work in overcoming resistance,

but the velocity energy of the stream of air is equally important in ventilation work.

(For experimental investigations as to efficiency of various types of fans, see *Minutes Proc. Inst. C. E.*, vol. cxxiii. p. 272; *Proceedings of Inst. Mech. Eng.*, 1897, p. 439, &c.)

Rotary Pressure Blowers.—These are machines introduced in comparatively recent years. They act by regular displacement of the air at each revolution, since their pistons or drums closely fit their cases. In this respect they differ from fans, because, although there were no outlet for the blast, a fan could be kept revolving, but in such a case a pressure blower would stop. The rotary blower by Roots of Connersville, Indiana (fig. 5),

Fig. 5.—Roots's Rotary Blower.

is one of the best known, and is now very largely used for producing blasts in metallurgical operations, as well as for other purposes, in America and Europe. A pair of horizontal shafts traverse a case of the form of two semi-cylinders, separated by a rectangle equal in depth to the diameter of the semi-cylinders, and in width to the distance between the centres of the shafts. These shafts carry a pair of solid arms or pistons, the relative positions of which are maintained by external gearing at both ends provided with safety coverings. Each has a section somewhat resembling a figure of eight, and their action, as they revolve, takes the air in by an aperture at the bottom of the machine, and expels it with considerable pressure, if required, at the top. It gives a much greater pressure of blast than is attainable by the fan.

The determination of the true shapes of the two solid arms or pistons is a similar problem to that of determining the profiles of the teeth of two toothed wheels which have to mesh with one another, and to transmit a constant velocity ratio; the solid arms must, in fact, while sliding over one another, transmit the same velocity ratio as would be transmitted by their corresponding pitch circles. The object of the pistons is to preserve contact, the external gears transmitting the necessary forces from the one to the other.

Blowitz, HENRI GEORGES DE (1825-1903), a Bohemian Jew, *Times* correspondent in Paris.

Blowpipe, a small instrument used in the arts for glass-blowing and soldering metals, and in analytical chemistry and mineralogy, for determining the nature of substances by the action of an intense and continuous heat. Its utility depends on the fact, that when a jet of air or oxygen is thrown into a flame, the rapidity of combustion is increased, while the effects are concentrated by diminishing the extent or space originally occupied by the flame.

The blowpipe generally consists of a conical tube of metal, about 8 inches long (see fig.), closed at the wider or lower end, but open at the narrow or upper end, which latter constitutes the mouthpiece, and

is turned over to admit of the lips closing perfectly round it. Near the lower end, a small tube, fitted with a finely perforated nozzle, *a*, is inserted in the large tube—the space below being intended as a chamber for condensing the moisture of the breath, and through this nozzle, a fine current of air can be projected against the flame experimented with.

Blowpipe.

The use of the mouth blowpipe, so as to sustain a prolonged steady blast, requires some skill, and is at first very fatiguing to the learner. In breathing, the manipulator involuntarily closes the back of the mouth, retaining in the expanded cheeks sufficient air to last till the lungs have been replenished through the nose. Where high temperatures are required mechanical blowpipes are resorted to.

When a current of air from the blowpipe is directed against a candle or gas-jet, the flame almost entirely loses its luminosity, owing to the perfect combustion of the gases evolved from the source of heat, and is projected in a lateral direction, as a long pointed cone, consisting of three distinct parts. The first or central cone is of a dark-blue colour, and there the combustion is complete from the excess of air thrown in from the small nozzle. The second cone, or that immediately surrounding the first, is somewhat luminous; and here the oxygen being insufficient for the combustion of the carbon, any metallic oxide subjected to the action of this portion of the flame is deprived of its oxygen, and reduced to the condition of metal; for this reason the luminous cone is generally termed the *reducing flame* of the blowpipe. Beyond the second cone, or where the flame comes freely in contact with the atmosphere, and abundance of oxygen is present to effect complete combustion of the gases, is a third, or pale yellow envelope, containing excess of atmospheric air at a very high temperature, so that a portion of metal, such as lead or copper, placed at this point, becomes rapidly converted into its oxide; this outer part of the flame is on this account called the *oxidising flame* of the blowpipe.

Substances under examination before the blowpipe are generally supported either on wood-charcoal or platinum—the latter in the condition of wire or foil. In applying the blowpipe test, the body to be examined is either heated alone, or along with some flux or fusible substance; this being added, in some cases, for the purpose of assisting in the reduction of metals from their ores and other compounds: in others, for the production of a transparent glassy bead, in which different colours can be readily observed. When heated alone, a loop of platinum wire, or a piece of charcoal, is generally employed as a support; the former when the colour of the flame is to be regarded as the characteristic reaction, the latter when such effects as the oxidation or reduction of metallic substances are to be observed.

The following are examples of the difference in colour communicated to the flame by different

substances: Salts of potash colour the flame *violet*; soda, *yellow*; lithia, *purplish red*; baryta, *yellowish green*; strontia, *carmine*; lime, *brick red*; compounds of phosphoric acid, boracic acid, and copper, *green*. The commonly occurring metallic oxides reducible by heating on charcoal alone in the inner flame of the blowpipe are the oxides of zinc, silver, lead, copper, bismuth, and antimony; the principal ores not so reducible are the alkalies and alkaline earths, as also the oxides of iron, manganese, and chromium. The fluxes generally used in blowpipe experiments are either carbonate of soda, borax (biborate of soda), or the ammoniaphosphate of soda, otherwise called *Microcosmic Salt* (q.v.). The carbonate of soda, when heated on platinum-wire in the oxidising flame, forms with silica a *colourless glass*; with oxide of antimony, a *white bead*, &c. The following metals are reduced from their compounds when heated with carbonate of soda on charcoal in the inner flame of the blowpipe: viz. nickel, cobalt, iron, molybdenum, tungsten, copper, tin, silver, gold, and platinum. When compounds of zinc, lead, bismuth, arsenic, antimony, tellurium, and cadmium are similarly treated, these metals are also formed, but being volatile, pass off in vapour at the high temperature to which they are exposed.

Borax, as a flux, is generally mixed with the substance under examination, and placed on platinum-wire. When thus heated in either of the flames, baryta, strontia, lime, magnesia, alumina, and silica, yield *colourless beads*; cobalt gives a *fine blue colour*; copper, a *green*, &c. With microcosmic salt, the results obtained are generally similar to those with borax, and need not be specially mentioned, as the test is applied in the same way. The blowpipe has been long used by goldsmiths and jewellers for soldering metals, by glass-blowers in fusing and sealing glass-tubes, &c., by chemists in qualitative, and even quantitative, analysis—the advantages being the small quantities required, and rapidity of working.

The *oxyhydrogen blowpipe* is an arrangement by which a jet of oxygen and hydrogen, in the proportions to form water, is ignited and directed against any object. The most intense heat is produced, most of the metals being volatilised when placed in it, and even the diamond changes into ordinary carbon and is burned when exposed to its flame. When a cylinder of quicklime is heated by it, a most dazzling light is produced, rivaling the electric light in brilliancy, and known as the *Drummond Light* (q.v.).

The *oxyacetylene blowpipe* has been more recently introduced, and gives a more intense heat than the oxyhydrogen. A special type of burner is used, fed from a cylinder of acetylene gas dissolved in acetone. This blowpipe is of great use in welding steel, and making repairs in steel machinery.

Blowpipe, a kind of weapon much used by some of the Indian tribes of South America, both in war and for killing game. It consists of a long straight tube, in which a small poisoned arrow is placed, and forcibly expelled by the breath. The tube or blowpipe, called *gravatína*, *pucuna*, &c., is 8 to 12 feet long, the bore not generally large enough to admit the little-finger. It is made of reed or of the stem of a small palm. Near Pará, it is in general very ingeniously and nicely made of two stems of a palm (*Iriartea setigera*) of different diameters, the one fitted into the other. In some places the inner tube is formed of the thin stem of a reed, protected by an outer one of this palm. A *sight* is affixed to it near the end. The arrows used in that district are 15 to 18 inches long, made of the spines of another palm, sharply pointed, notched so as to break off in the wound, and their points covered with *Curari* (q.v.) poison. A little soft

down of the silk-cotton tree is twisted round each arrow, so as exactly to fit the tube. In Peru, arrows of only 1½ to 2 inches long are used, and a different kind of poison seems to be employed. An accidental wound from one of these poisoned arrows not infrequently proves fatal. In the hand of a practised Indian, the blowpipe is a very deadly weapon, and particularly when directed against birds sitting in the tops of high trees. As his weapon makes no noise, the hunter often empties his quiver before he gathers up the game, and does more execution than an English sportsman could with his double-barrelled fowling-piece. In Borneo, the Dyaks have a similar blowpipe called a *sumputan*. It, however, has an iron spear-head tied on the end so that it can be used as a spear. It is employed both in war and in hunting. Small arrows, which have on their end a piece of pith adapted to the bore of the tube, are used. These are pointed with sharp fish-teeth and poisoned with upas. They are blown with great accuracy; and if the upas-juice is fresh, a wound from an arrow, fired at a distance of 40 yards, proves fatal to man. See POISON.

Blubber. See WHALE.

Blücher, GEBHARD LEBERECHEIT VON, Prince of Wahlstadt, Field-marshal of Prussia, was born at Rostock, in Mecklenburg-Schwerin, December 16, 1742. In 1757, shortly after the commencement of the Seven Years' War, he joined a regiment of Swedish hussars, and in his first action was taken prisoner by the Prussian hussars, whose colonel persuaded him to exchange out of the service of Sweden into that of Prussia, and gave him a lieutenancy. He attained the rank of captain, but his dissipated habits lost him the favour of his colonel, who promoted a younger officer over his head, and Blücher, in 1772, left the service in disgust. He retired to his estate of Grossradow, in Pomerania, and for fifteen years devoted himself to farming. In 1793, having returned to the army, he fought, as colonel of hussars, against the French on the Rhine, evincing great genius as a leader of cavalry. The breaking out of the war of 1806 led him, as lieutenant-general, to the battle of Auerstadt. He, with the greater part of the cavalry, occupied the left flank of the Prince of Hohenlohe's army in the retreat to Pomerania. Blücher himself marched into the territory of the free town of Lübeck, and hastily fortified the city; but the French took it by storm, and he was forced to surrender at Ratkau, whither he had escaped with a few troops. A fortnight after, he was exchanged for the French general Victor, and was sent, at the head of a corps, to assist in the defence of Stralsund. After the peace of Tilsit, he was employed at Königsberg and Berlin, and subsequently became commander in Pomerania. When the Prussians at last rose in opposition to France, Blücher was appointed to the chief command in Silesia, and at the battles of Lutzen, Bautzen, and Haynau, he displayed heroic courage. At the Katzbach, he defeated Marshal Macdonald, and cleared Silesia of the enemy. In vain did Napoleon himself attempt to stop the 'old captain of hussars,' as he called him, in his victorious career.

In the battle of Leipzig he won great advantage over Marshal Marmont at Möckern, October 16, 1813; and on the 18th, in conjunction with the crown prince of Sweden, he had a great share in the defeat of the French, his troops being the first to enter Leipzig, the next day. In January 1814 he crossed the Rhine, and after winning the battle of La Rothière, pressed forward to Paris; but his scattered corps were routed by Napoleon, and he fought his way back to Châlons with great loss. On the 9th March, however, he defeated Napoleon at Laon; and at the end of the month he again

advanced towards Paris, although sickness compelled him to make the journey in a wagon. The day at Montmartre crowned the brilliant deeds of this campaign, and, on the 31st March, Blücher entered the French capital. Frederick-William III. created him Prince of Wahlstadt, in remembrance of the victory at the Katzbach, and gave him an estate in Silesia. In England, whither he followed the Allied Sovereigns, he received the freedom of the city of London, and the university of Oxford conferred on him the degree of Doctor of Laws. After Napoleon's return in 1815, Blücher once more assumed the general command, and promptly led the army into the Netherlands. On June 16, 1815, he suffered a severe defeat at Ligny, but he personally rallied his scattered troops, and Wellington's victory at the battle of Waterloo was completed by his timely appearance on the field. Blücher despatched his Prussians after the fleeing enemy, and the pursuit lasted all through the night. Declining the offered truce, he marched again against Paris, and on the second taking of that city manifested a strong desire to retaliate on Paris the spoliation that other capitals had suffered; but he was held in check by the Duke of Wellington. In order to reward Blücher's services, Frederick-William III. created a new order, the badge of which consisted of an iron cross surrounded by golden rays. In 1819 a colossal bronze statue was erected in his honour in his native town, and others were afterwards raised in Breslau and Berlin. He died September 12, 1819, after a short illness, at his estate of Kriebowitz, in Silesia. 'Marshal Forwards' was not a great tactician, his victories being due mainly to his dash and energy. In speech and behaviour he was rough and uncultivated; his character was a noble compound of frankness, valour, integrity, and loyalty, and he remains a German hero. His statue at Breslau is Rauch's masterpiece.

See *Lives* by Forster (new ed. 1887), Scherr (new ed. 1887), and E. F. Henderson (1911), and books about the Waterloo campaign. The story that, looking at London, Blücher exclaimed, 'What a place to plunder!' seems to rest on a mistake. What he said was, 'Was für Plunder!' ('What rubbish!'), with reference to the mean streets he saw about him.

Blue. The blue pigments in common use by artists are few in number, and consist of native and Artificial Ultramarine, Cobalt, Indigo, and Prussian Blue (q.v.). Genuine ultramarine, prepared from the mineral lapis lazuli, and ordinary cobalt blue, sold for artists' work, are permanent colours. They are used either alone, or mixed with other pigments, chiefly for skies and distances in landscape; and by themselves, or to make up grays and other mixed tints in figure-painting. Owing to the exceptionally high price of real ultramarine, the artificial colour, which is of doubtful permanency, is usually substituted for it. Prussian blue and indigo are highly useful colours, since it is only these that yield dark blues, and only from them, mixed with yellows or browns, that strong greens can be obtained. It is unfortunate accordingly that both are more or less fugitive. All the blues above named are used both in oil and water-colour painting, but indigo less than the others in oil, since it is most apt to fade in that medium.

A number of different names are used in commerce for what is essentially the same pigment, or for pigments closely resembling one another. The following statement gives some explanation of these.

Cobalt blues are mixtures of cobalt with earthy or metallic bases, which have been subjected to the action of heat, and have received the following names: Cobalt blue, cerulean blue, royal blue,

Dumont's blue, Saxon blue, Thenard's blue, Leithner's blue, Hungary blue, Zaffre or enamel blue, Vienna blue, azure blue, and Paris blue. The last name is also applied to a Prussian blue, and azure is also given to a variety of ultramarine blue.—*Smalt* is a powdered cobalt glass used in illumination and flower-painting.—*Artificial ultramarine* is also called French ultramarine, French blue, new blue, and permanent blue. Coarse qualities of this colour are largely used by house-painters.—*Intense blue* is a refined indigo.—*Prussian blue* (sesquiferrocyanide of iron) is otherwise named Berlin blue, Paris blue, and ferrocyanide of iron. The name Paris blue is also given to a cobalt colour.—*Antwerp blue* is a variety of Prussian blue made lighter by the addition of an aluminous base, and not so permanent.—*Blue ochre* (hydrated phosphate of iron) is a subdued permanent blue, but not much employed.—*Blue verditer* is a hydrated oxide of copper which changes and ultimately blackens by time. It is used in distemper work and paper-staining.

Blue was worn as a distinctive colour by the Scottish covenanters, and is in some places used by Conservatives. The traditional Whig colour was blue also, or blue and buff. *Navy blue* is a dark blue. Dark blue is the Oxford colour, light blue the Cambridge one.

For Blue Dyes, see DYEING; and for blue colours used in the manufacture of GLASS and POTTERY, see these heads. *Blueing* is a name for indigo or any material used for giving a bluish colour to linen. See also TEMPERING.

Bluebeard, the hero of a well-known nursery tale, so named from the colour of his beard. The story is widely known in Western Europe, but the form in which it has become familiar in England is not an independent version, but a free translation of that given by Perrault in his famous *Contes* (1697). In this story Bluebeard is a seigneur of great wealth, who marries the daughter of a neighbour in the country, and a month after the wedding goes from home on a journey, leaving his wife the keys of his castle, but forbidding her to enter one room. She cannot resist her curiosity, opens the door to find the bodies of all Bluebeard's former wives, and at once sees the fate to which she herself is doomed. Bluebeard on his return discovers, from a spot of blood upon the key, which would not be cleaned off, that his wife had broken his command, and tells her that she must die. She begs for a short respite to commend herself to God, sends her sister Anne to the top of the tower to look round if any help is near, and finally is just on the point of having her head cut off, when her two brothers burst in and despatch Bluebeard.

Nothing is more common in folk-tales than stories of forbidden rooms, the entrance into which is at once followed by severe punishment. In the eastern stories, according to Mr Clouston, the room does not usually contain anything very horrifying, unlike most of the western examples of which the story of Bluebeard is a type. A very close parallel to the classical form of the story is offered by a Swabian tale in Grimm's collection; so close, indeed, that in later editions than the first, Grimm omitted it as probably a direct loan from the French. Greek, Tuscan, Icelandic, Estonian, Gaelic, and Basque versions of the story occur, with varying circumstances of detail, but the main situations identical. Bluebeard is usually a monster or ogre, and lives fittingly in the gloom of forest or cavern—the only really essential detail that has dropped out of the typical story. In one group the monster is the devil, and the forbidden door closes the entrance to hell. In many stories the heroine is the youngest of three or more sisters who have been less lucky, and sometimes, as in one of Camp-

bell's Gaelic variants, she is able to restore them to life. In Campbell's other version, as in the Basque story, it is the heroine herself who cuts off the monster's head.

In the face of such a wide geographical range and self-evident antiquity it is as idle to look for an historical 'Bluebeard' in Gilles de Laval, sire de Rais (see RETZ), as it would be to find him in Henry VIII., who was so unfortunate with his wives.

Use has been made of the story by Tieck in his *Phantasus*, by Anatole France in *Les Sept Femmes de la Barbe Bleue* (1909), by Gtéry, Dukas, Reznicek, Bartók, in operas. See 'The Forbidden Chamber' by Sidney Harland in *The Legend of Perseus* (1894-96), Andrew Lang's edition of Perrault's *Contes* (1887), and Vizetelly's *Comorre the Cursed and Gilles de Rais* (1902).

Blue-bell is the English name of the common wild hyacinth (*Scilla festalis* or *S. nutans*; see SQUILL, HYACINTH). The 'blue-bells' familiar alike in the everyday rural associations and in the poetic literature of Scotland are the flowers of *Campanula rotundifolia*, commonly called Harebell in English (see CAMPANULA, HAREBELL).

Bluebird, **BLUE WARBLER**, **BLUE RED-BREAST**, or **BLUE ROBIN** (*Sylvia or Sialia sialis*), an American bird, which, from the confidence and familiarity it displays in approaching the habitations of men, and from its general manners, is much the same sort of favourite with all classes of people in the United States as the redbreast is in Britain. Except in the southern states, it is chiefly known as a summer bird of passage, appearing early, however, as a harbinger of spring, and visiting again 'the box in the garden, or the hole in the old apple-tree, the cradle of some generations of ancestors.'

Bluebird (*Sylvia sialis*).

Their soft agreeable note strikes one of the hours on the living timepiece of the seasons, and has been beautifully called by Burroughs the 'violet of sound.' They are celebrated in American poetry; thus Lowell speaks of

The bluebird, shifting his light load of song
From post to post along the cheerless fence.

Few American farmers fail to provide a box for their nest. In size the bluebird rather exceeds the redbreast, which, however, it much resembles in general appearance. Its food is also similar. The upper parts of the bird are of a rich sky-blue colour, the throat and breast are reddish chestnut, and the belly white. The female is duller in colours than the male. It lays five or six pale-blue eggs, and has two or three broods in the season. The male is remarkably attentive to his mate, and both exhibit extraordinary courage in driving away intruders from the vicinity of their nest. A hen, with her brood, has been seen to flee from the attacks of an

enraged and pugnacious bluebird. The bluebird is known as an inhabitant of the Bermudas, Mexico, the West Indies, Guiana, and Brazil.—In the western and in the more northern parts of North America its place is taken by nearly allied and very similar species. The name Bluebird is also applied to a number of other birds, as the Indian *Irene puella* (a member of the bulbul family or *Pycnonotidae*), and the sooty albatross (see ALBATROSS). Maeterlinck's Blue Bird is, of course, outside the classification of ornithologists.

Blue Blanket, the banner of the Edinburgh craftsmen, traditionally connected with Pope Urban II., was granted by James III. about 1482, when Edinburgh helped him out of his money difficulties. 'If in anything they be controlled,' says the *Basilicon Doron*, 'up goeth the blue blanket.' See FLAG (*Standard*).

Blue-books, the name popularly applied to the reports and other papers printed by parliament, because they are usually stitched up in blue paper wrappers. Some departments, however, issue their proceedings in diabol, and some in white, covers. The practice of printing, and to some extent publishing, the proceedings of the House of Commons began in the year 1681, when disputes ran high on the question of excluding the Duke of York from the succession to the throne. It was stated that false accounts of the transactions were circulated, and, as a remedy, Sir John Hotham moved that the votes and proceedings of the House be printed. The motion, after considerable discussion, was carried. The documents printed by the House of Commons grew gradually in bulk and variety, until they reached their present extent. In 1836 the House adopted the practice of selling their papers at a cheap rate, and has since that date gradually increased the facilities offered to the public for acquiring parliamentary papers. Since August 1886, under the authority of the President of the Board of Trade, a most useful journal has been issued each month by that department. It contains in addition to its official notices much valuable information from British, colonial, and foreign sources relating to the trade of the world. The publications issued under the superintendence of His Majesty's Stationery Office include Papers and Bills of the House of Lords, Bills of the House of Commons, Reports and Papers of the House of Commons, and Papers by Command. The chief contents of these papers are the votes and proceedings of the House; the bills read in their several stages; the estimates for the public services of each year; the accounts of the expenditure of the moneys voted in the previous year; any correspondence or other documents which the ministry may voluntarily, or at the demand of the House produce, as connected with a question under discussion; reports of committees of inquiry appointed by the House; reports of commissions of inquiry appointed by the crown; and annual reports by the permanent commissions and other departments of the government, stating their proceedings during the year. The blue-books of a session, when collected and bound up, now fill many thick folio volumes. Nothing can seem more hopelessly chaotic than those of a few sessions huddled together unarranged. It deserves to be known, however, that they are all printed according to a peculiar sequence, which enables the whole papers of a session to be bound up in such an order that any paper can be found by consulting an ample index in the last volume. A *précis* of the contents also is now usually given at the beginning of each blue-book. In any library where the blue-books are preserved and properly bound up, the most trifling paper of any session may thus be found with ease; and it need hardly be said that with

much that is useless or unimportant, there is an enormous mass of valuable matter hidden in the blue-books. A treasury minute having reference to copyright in government publications provides that while no restrictions are put on their reproduction generally, the unauthorised publication of charts and ordnance maps is forbidden.

The official books of foreign governments corresponding to our blue-books are designated by the colour of their covers. The principal are: France, yellow; Germany and Portugal, white; Italy, green; and Spain, red. The United States government publishes a most valuable collection of reports on agriculture, manufactures, trade and commerce; the name blue-book is confined to the published lists of government employes and to the manuals of regulations for the navy; the foreign diplomatic correspondence is usually published in red.

Blue-bottle. See CORN-FLOWER.

Blue-bottle Fly (*Musca vomitoria*), an insect of the same genus with the common House-fly (q.v.). It much exceeds the latter in size, but is smaller than the Blow-fly (q.v.). The head is black, with rust-coloured cheeks, the thorax grayish, the abdomen blue, with a whitish shimmer, and with three black bands. It flies with a loud buzz. The expanse of wings is nearly one inch. It is abundant throughout Britain and Europe generally from spring to autumn, and deposits its eggs on flesh, for which purpose it often enters houses, having a remarkably delicate sense of smelling. The maggots are of very frequent occurrence on meat in summer, notwithstanding all care that can be taken.—*M. erythrocephala* is also called Blue-bottle.—A nearly allied species (*M. cesar*), the Green-bottle fly, is distinguished by its golden-green colour, and is also common in Britain, especially on excrement. The maggots develop from the egg in about twenty-four hours; the whole metamorphosis occupies about a month. *M. cornicina* is another common green-bottle. There are many other species. See FLY.

Blue Cardinal. See LOBELIA.

Blue-coat School, a name commonly given to Christ's Hospital (now at Horsham), and to similar schools in Bristol and elsewhere, the dress of whose scholars is a long dark-blue gown with a belt round the waist, and yellow stockings. Such dress is just that of boys in the first half of the 16th century. See CHRIST'S HOSPITAL.

Blue-eye (*Entomya cyanotis*), a beautiful little bird, abundant and very generally dispersed in New South Wales, although not found in Victoria. It is one of the Honey-eaters (q.v.) or Honey-suckers, and is sometimes called the Blue-cheeked Honey-eater. It seeks its food almost exclusively among the blossoms and small leafy branches of gum-trees (Eucalypti), and finds it partly in insects and partly in nectar, though perhaps also in berries. It is a bold and spirited bird, of most elegant and graceful movements. Numbers are often seen together clinging and hanging in every variety of position, frequently at the extreme ends of the small branches.

Bluefields. See BLEWFIELDS.

Bluefish (*Pomatomus saltatrix* or *Temnodon saltator*), a fish of the family Serranidæ, of a genus having no detached finlets, no isolated dorsal spines, and no lateral armature of the tail, two dorsal fins, the first of which is small, and two deeply-hidden spines in front of the anal fin. The only known species is abundant on the east coast of North America. It goes southwards in winter, migrates northwards in spring, and is widely spread in tropical and subtropical seas. The upper parts are of a bluish colour, the lower parts whitish, a

large black spot at the base of the pectoral fins. The mouth is crowded with teeth, the jaws are furnished with large ones. The bluefish preys on other fishes, such as the menhaden, and mackerel, the shoals of which it pursues. It is very swift, strong, and voracious. It sometimes attains a length of 3, or even 5 feet, and a weight of 14 lb. It is much esteemed for the table. It is often caught by trolling, as it bites readily at an object drawn swiftly through the water. It frequently ascends rivers even to fresh water.

Blue-gowns, the name commonly given to a class of privileged mendicants in Scotland. The proper designation of these paupers was the King's Bedesmen, or Beadsmen. In ancient times, a beadsman was a person employed to pray for another (see BEADS). From practices of this kind, there sprang up a custom in Scotland of appointing beadsmen with a small royal bounty, who ultimately degenerated into a class of authorised mendicants. Each of the beadsmen on his majesty's birthday received a gown or cloak of blue cloth, with a loaf of bread, a bottle of ale, and a leathern purse containing a penny for every year of the king's life. Every birthday, another beadsman was added to the number, as a penny was added to each man's purse. The most important part of the privilege was a large pewter badge, attached to the breast of the gown, which, besides the name of the bearer, had the inscription, 'Pass and Repass.' This inferred the privilege of begging, and bespoke the kindly consideration of all to whom the beadsman appealed for an alms or a night's lodging. The fictitious character of Edie Ochiltree, in Sir Walter Scott's tale of the *Antiquary*, is a fair sample of this ancient and picturesque fraternity. The practice of appointing beadsmen was discontinued in 1833, at which time there were sixty on the roll. The whole have since died out. The last beadsman drew from the Exchequer in Edinburgh his last allowance in May 1863.

Blue Grass (*Poa pratensis*) is a permanent grass found in Europe and North America. By reason of its creeping root-stocks it forms a dense turf, but is more valued for pasture than for cropping. The blue grass pastures of Kentucky, where it grows spontaneously, have long been celebrated. It is also called June grass. See GRASSES, PASTURE.

Blue-jay (*Cyanocitta cristata*), a common North American bird of the Crow family, and occupying in the New World the place held by the jays (*Garrulus*) of the Old. In the United States the blue-jay is sometimes persecuted, sometimes protected, becoming as shy and cunning in the one case, as he is familiar and impudent in the other. They are mischievous birds, but devour large numbers of injurious caterpillars. The length of the bird is almost a foot; the colour is 'grayish purple above, black on the neck, lilac-brown to white below.' The common blue-jay has a wide distribution, and there are several other North American species. The long-tailed blue-jays belong to a rarer genus (*Xanthura*) found in Central and in South America. See JAY.

Blue John. See FLUOR-SPAR.

Blue Light. See BENGAL LIGHT.

Blue Mountains, a spur which juts out from the Main Dividing Range in New South Wales, west-north-west of Sydney. It is really the remains of an old sandstone tableland into which the Grose River on the north and the Cox on the south have eaten deeply, edging it with cliffs from 600 to 1000 feet in the sheer. The main road and railway to the inland plains run along the spur by a route discovered in 1813; the 'Zigzags,' by which the railway ascended and descended, are now both

done away with. The principal settlement is at Katoomba, 3300 feet high, but all along the line are scattered summer resorts for the people of Sydney. The Jenolan Caves (q.v.) are sometimes spoken of as in the Blue Mountains, but are thirty miles south-west in the heart of the Main Range. See also JAMAICA.

Blue Peter, a blue flag with a white rectangle in the centre, hoisted when a ship is about to sail.

Blue Pill (*Pihula hydrargyri*) is the most simple form in which mercury can be administered internally. It consists merely of two parts of mercury rubbed up with three parts of conserve of roses, till globules of mercury can no longer be detected; to this is added one part of powdered liquorice-root, so that a pill of three grains contains one grain of mercury. In cases of torpid condition of the liver or inflammation of that organ, blue pill is much used as a purgative, either alone or combined with some other drug, such as rhubarb. When it is given with the view of bringing the system under the influence of mercury (see SALIVA), small doses of opium should be added to counteract its purgative tendency, and the state of the gums watched carefully from day to day, so that the first symptoms of salivation may be noticed, and the medicine omitted. As a purgative, the common dose of blue pill is one or two pills of five grains each, followed by a purgative draught. But sensibility to the action of mercury varies with the individual. When one is taking blue pills, all sudden changes of temperature should be avoided, and neither they nor any other form of mercury should be given without good cause and without the greatest caution.

Blue Ribbon, a term applied to any great prize—as the 'Derby' stakes—from the blue ribbon worn by knights of the Garter.—*Blue Ribbon Army* was the name adopted, from the badge, by the association of total abstainers founded in 1878 by Mr Murphy in America.

Blue Ridge, one of the southern ranges of the Appalachians (q.v.).

Blue Roach. See AZURINE.

Blue Sky Laws, in the various American states, seek to prevent fraud in the selling of stocks.

Blue Slipper. See GAULT.

Blue-stocking, a name given to learned and literary ladies. The name is derived from a literary coterie formed in London about the year 1750, which included both men and women, and *Bas Bleus* is a French translation. But it has been much disputed whether the name came to be given because a male member, Benjamin Stillingfleet, habitually wore blue (or gray) worsted stockings, when black silk were *de rigueur*; or because one or more of the ladies followed the Duchesse de Polignac and the newest Paris fashion. Mrs Montagu was called 'the Queen of the Blue Stockings'; see an article in the *Quarterly Review* for January 1903, and Mrs E. R. Wheeler's *Famous Blue Stockings* (1910), which deals also with Mrs Delany, Mrs Chapone, Mrs Vesey, Elizabeth Carter, Hannah More, Fanny Burney, and Mrs Thrale.

Bluestone, or BLUE VITRIOL. See COPPER.

Bluethner, JULIUS FERDINAND (1824-1910), born at Falkenhain, near Merseburg, set up his famous pianoforte house in Leipzig in 1853.

Bluethroat, or BLUEBREAST (*Cyanecula suecica*), a beautiful and melodious bird, nearly allied to the nightingale. From its power of imitating the notes of other birds the Laplanders give it a name which signifies the bird of a hundred tongues. Another of its many names is *Luscinia suecica*, or Swedish Nightingale. It is

very little larger than a redbreast, and much resembles it, but has the throat and upper part of the neck of a brilliant light-blue, with a spot in the centre, which in some specimens is pure white, and in very old males is red. The females have less blue. Below the blue colour is a black bar, then a line of white, and again a broad band of bright chestnut. The bluethroat is well known as a summer bird of passage in many parts of Europe, from the Mediterranean Sea to the Arctic Ocean, but is very rare in Britain, only a few instances of its occurrence having been recorded. It is supposed to spend the winter in Africa. The bird is one of those known by the names of Becfin and Beccafico (q.v.), and unfortunately falls victim to epicure tastes.

Blue-wing, a kind of duck, either a sub-genus of *Anas*, or a special genus *Cyanopterus*. The latter title and the popular name refer to the conspicuous colour. The best-known species, the Common or Lunate Blue-wing (*Anas* or *Cyanopterus discors*), is generally called the Blue-winged Teal in the United States of America, where it is very abundant. Vast numbers spend the winter in the extensive marshes near the mouths of the Mississippi, to which they congregate both from the north and from the coast regions of the east; but the summer migrations of the species extend as far north as the 57th parallel, and it is plentiful on the Saskatchewan in the breeding-season. It breeds, however, also in the marshes of the south, even in Texas; and is common in Jamaica, where it is supposed to be not a mere bird of passage, but a permanent resident. In size it is rather larger than the common teal; in the summer plumage of the male, the upper part of the head is black, the other parts of the head are of a deep purplish blue, except a half-moon shaped patch of pure white before each eye; the prevalent colour of the rest of the plumage on the upper parts is brown mixed and glossed with green, except that the wings exhibit various shades of blue, the lesser wing-coverts being of a rich ultramarine blue, with an almost metallic lustre; the lower parts are reddish orange spotted with black; the tail is brown, its feathers short and pointed. The flight is extremely rapid and well sustained. The flocks are sometimes so numerous and so closely crowded together on the muddy marshes near New Orleans, that Audubon mentions having seen 84 killed by the simultaneous discharge of the two barrels of a double-barrelled gun. There are other species of blue-wing, also American; but this alone seems to visit the more northern regions. No member of the duck tribe is in higher esteem for the table, and it has therefore been suggested that the blue-wing is particularly worthy of domestication, of which it seems to be very easily susceptible.

Blum, ROBERT, born in very humble circumstances at Cologne in 1807, was secretary and treasurer of a theatre at Cologne, and subsequently at Leipzig, until 1847, when he established himself as bookseller and publisher. His leisure was devoted to literature and politics, and in 1840 he founded at Leipzig the Schiller Society, which celebrated the poet's anniversary, as a festival in honour of political liberty. When the revolutionary movement broke out in 1848, Blum was one of its most energetic leaders. He was elected one of the vice-presidents of the provisional parliament at Frankfurt, and as such ruled that turbulent assembly by presence of mind and a stentorian voice. In the National Assembly he became leader of the Left, and was one of the bearers of a congratulatory address from the Left to the people of Vienna, when they rose in October. At Vienna he joined the insurgents, was arrested, and was shot

on the 9th November. Blum was a man of strong character, great natural intelligence, and stirring eloquence. The news of his execution excited great indignation among the democrats in Germany, who, besides instituting commemorations for the dead, made an ample subscription for his widow and children. See the Life by his son (Leip. 1878).

Blumenbach, JOHANN FRIEDRICH, a very eminent naturalist, whose influence extended to almost all branches of natural science, was born at Gotha, 11th May 1752. He studied at Jena and Göttingen, and at Göttingen he became extraordinary professor in 1776, and ordinary professor in 1778. Here he lectured for nearly 60 years on natural history, comparative anatomy, physiology, and the history of medicine. In 1785, consequently before Cuvier, he made natural history dependent on comparative anatomy, and zoology in his hands first attained full scientific rank, the real relations of animals being definitely ascertained. His doctor's disputation, *De Generis Humani Varietate Nativa* (1775), raised the great question as to the unity of the human race; his *Institutiones Physiologicae* (1787), and other treatises, gave a decided impulse to scientific research. His *Manual of Natural History* (1780) went through 12 editions in 50 years. His *Manual of Comparative Anatomy and Physiology* (1804) was translated into almost all the principal languages of Europe. The natural history of man was always a favourite study; and his *Collectio Craniorum Diversarum Gentium*, commenced in 1790, and completed in 1828, gave to the learned world the result of his observations on the skulls of different races, of which he had an extensive collection (see SKULL, ETHNOLOGY). He published other valuable works on natural history, and many essays and papers. Both as a writer and a lecturer he was eminently successful. In 1788 and 1792 he visited England, where he met with a distinguished reception from the most famous naturalists. On the 19th September 1825, his friends and pupils in all countries celebrated the jubilee of his doctorate. In 1835 the increasing infirmities of age compelled him to resign his academical functions. He died on the 22d January 1840. See Marx's Memoir (1840), and the work *Göttinger Professoren* (1872).

Blumenthal, JACQUES (1829-1908), pianist, born in Hamburg, studied under Herz, and in 1849 went to London, where he was pianist to the queen, taught music, and composed many brilliant, pretty pieces and popular songs.

Blundell's School. See TIVERTON.

Blunden, EDMUND, one of the best of English 20th-century poets, was born in 1896, was educated at Christ's Hospital and Queen's College, Oxford, and fought in the Great War. His *Pastorals* (1916), and some other early volumes, were followed by *The Waggoner* (1920), in which accurate and sympathetic observation of nature was combined with craftsmanship of high accomplishment. *The Shepherd and other Poems of Peace and War* (1922) showed his qualities in greater maturity, and brought more of his own experience into his poetry. *The Bonadventure* (1922), the story of a voyage in a tramp steamer, proved him an accomplished writer of prose. He became professor of English at Tokyo in 1924.

Blunt, JOHN HENRY, D.D. (1823-84), theologian, born at Chelsea, was for some years engaged as a manufacturing chemist, but in 1850 entered the university at Durham. He held several minor preferments, till in 1873 he received the crown living of Beverstone, Gloucestershire.

Blunt, JOHN JAMES (1794-1855), divine, born at Newcastle-under-Lyme, in 1812 entered St John's College, Cambridge, graduated fifteenth

wrangler, and obtained a fellowship. A curate in Shropshire, then rector of Great Oakley, in Essex, he became in 1839 Lady Margaret professor of Divinity at Cambridge. In 1854 he declined the bishopric of Salisbury. His best-known work is *Undesigned Coincidences* (1833). See Selwyn's memoir prefixed to *Two Introductory Lectures* (1856).

Blunt, WILFRID SCAWEN (1840-1922), traveller and poet, was born at Petworth. His mother being a Catholic convert, he was educated at Stoneyhurst and St Mary's, Oscott. He served for some years as attaché to various British embassies in Europe and South America; married in 1869 Anne, daughter of the Earl of Lovelace, and granddaughter of Lord Byron (afterwards Baroness Wentworth); and travelled through Spain, Algeria, Egypt, and the Syrian desert, as recorded in his wife's *Bedouins of the Euphrates*. In 1882 he championed the cause of Arabi Pasha in Egypt. The same sympathy with national aspirations afterwards plunged him into the Nationalist cause in Ireland, and led to his being imprisoned for two months in 1887-88 for taking part in a prohibited meeting in County Galway. Blunt was the author of several volumes of verse, *Sonnets and Songs*, the *Love Sonnets of Proteus* (containing poetry of really striking merit), *Esther. Love Lyrics. The Wind and the Whirlwind* (on Egyptian affairs), *In Vinculis, Satan Absolved* (1899), &c. His complete *Poetical Works* were published in 1914, his very outspoken *Diaries* in 1919-20. He was a breeder of Arab horses.

Bluntschli, JOHANN KASPAR, jurist, was born 7th March 1808, at Zurich, where in 1833 he became professor in the new university. In politics he at first inclined to reform, but after 1839 was Conservative leader. He was a councillor of state, and became a member of the government and of the federal directory, and afterwards worked for the formation of a moderate Liberal-Conservative party in Switzerland. In 1848 he went to Munich as professor of Civil and International Law. There he published his *Allgemeines Staatsrecht* (5th ed. 1876), on which his reputation as a jurisconsult chiefly rests; *Deutsches Privatrecht* (3d ed. 1864); and, in conjunction with Arndts and Pözl, *Kritische Ueberschau der Deutschen Gesetzgebung und Rechtswissenschaft* (6 vols. 1853-58). In 1861 he removed to Heidelberg University, and became a privy-councillor of Baden, actively forwarding all liberal measures in the state. Liberty in ecclesiastical matters he had equally at heart; he acted several times as president of the *Protestantenverein*, and it was after delivering a closing speech at the general synod of Baden that he died suddenly at Karlsruhe, 21st October 1881. He is the author of valuable histories of Zurich and of the Swiss Confederation, and of a number of works on law, being especially an authority in international law. In 1884 his autobiography appeared in three volumes.

Blushing is a sudden reddening of the skin, induced by various mental states, particularly those involving shame or humiliation, shyness or modesty. It usually affects only the face and neck; rarely among civilised peoples the breast and other parts of the body. But 'the men of certain races, who habitually go nearly naked, often blush over their arms and chests, and even down to their waists' (Darwin). It is often accompanied by expressive movements; the face is turned aside, the eyes cast down or restlessly moved. It causes increased heat of the parts affected, with a sensation of heat and tingling, and often a general feeling of discomfort. It does not occur in young children.

Blushing is an excellent illustration of the control exercised over the circulation of the blood by the nervous system. Under ordinary circumstances, the muscular coat of the small arteries throughout

the body is constantly maintained in a state of partial contraction by means of the nerves distributed to it (*vasomotor* nerves; see NERVOUS SYSTEM). The blood propelled into them by the heart is thus prevented from distending them to their full extent, and its passage to the capillaries in connection with them is controlled. When, however, from any cause the action of these nerves is suspended, the arteries under their influence at once dilate, the corresponding capillaries become fuller, and the tissues containing them appear much redder than in their ordinary condition.

Under the influence of shyness, shame, &c. an alteration takes place in the nervous influence proceeding from the brain, which, for the time, lessens or stops the action of the nerves controlling the arteries of the skin of the face and neck, and blushing is the consequence. Why it should result from these and not from other mental states, and why the effect should be confined in general to the face and neck, are much more intricate questions, which cannot be discussed here. For one answer to them, with many interesting facts on the subject, see Darwin, *Expression of the Emotions*, chap. xiii.

Boa, a term popularly applied to the large snakes of the Python and Boa Constrictor families. The former are Old-World, the latter New-World giants, and closely resemble one another both in structure and habit. Both are very large, not poisonous, with great powers of crushing, with an expansible gape, with prehensile tails, with rudimentary traces of the hind-legs beside the anus, and so on. Apart from general difference of habitat, the two families may be distinguished by the facts that in the pythons the premaxillæ (most anterior upper jaw-bones) bear teeth, but not in the boas; that the inferior shields of the tail are in two rows in the former, in one in the latter. Leaving the python family meanwhile, we may resume the characters of Boidæ in the strict sense.

Head of Boa.

The body of these large non-venomous crushing snakes is slightly compressed sideways, and is covered with smooth or keeled scales. The gape, tail, and hind-legs are referred to above. The genus *Boa* itself has smooth scales, a scaly head, lateral nostrils, and characteristic arrangement of shields. The common species (*Boa constrictor*), found in the north and east of South America, is usually about 12, but, according to report, may be over 20 feet in length. The colour of the back is reddish gray, with zigzag, broad, dark longitudinal stripes, including oval grayish-yellow spots; the head exhibits three dark stripes. It frequents dry bushy regions, is shy of man, and

little feared. To a large extent arboreal in its habits, it is aided in climbing by the rudimentary claw-like hind-limbs. From its concealment the boa swoops down on even comparatively large mammals, crushes them in its coils, and swallows them slowly. The bones are broken by the external crushing, a copious flow of saliva within the mouth makes the laborious swallowing of the large mass somewhat easier, but it is at the best a tedious and exhausting process. After a meal comes a period of digestion and quiescence, and in this state of torpid lethargy they may be readily killed. On waking up they are very hungry, and the demands of appetite at this time prompted a boa in the Zoo to swallow its rug, which, after a week or two of unsuccessful digestion, it put up again. Like other Boidæ, the boa is oviparous, but a case of viviparity in captivity has been recorded. Its skin is used for making boots, saddles, covers, &c. The great water-snake Anaconda (*Eunectes murinus*), the Xiphosoma of the Amazon district, the Enygrus of Java, Amboyna, and New Guinea, with keeled scales, are closely allied genera of Boidæ. See ANACONDA, PYTHON, SNAKES.

Boabdil (properly Abu-Abdallah, and nicknamed Ez-Zogoby, 'the unlucky'), the last Moorish king of Granada, dethroned his father, Abu-l-Hasan, in 1481, and two years later was defeated and taken prisoner by the Castilians near Lucena. He was set free on condition of paying tribute, and returned to Granada to struggle with his father and with his heroic uncle, Ez-Zaghal, for the throne. Thus the Moors wasted the strength they sorely needed for the final struggle with the Christians. The fall of Malaga and Baza was but the prelude to the siege of the capital itself, which was finally starved out towards the close of 1491, spite of the reckless courage of the Moors and of Boabdil, whose weak and vacillating nature fell from him in the hour of battle. The unhappy king gave up to Ferdinand the keys of the city, then turned his back on Granada, and rode on towards the mountains. At Padul, on a spur of the Alpujarras, he turned to take a last look at the towers of the fair palace and city he had lost. 'Allahu Akbar' ('God is great'), he exclaimed, as he burst into tears. His mother stood beside him. 'You may well weep like a woman,' she said, 'for what you could not defend like a man.' The spot from which Boabdil looked his last on Granada still bears the name of *el ultimo suspiro del Moro*, 'the last sigh of the Moor.' He soon crossed to Africa and flung away his life in battle.

Boadicea (also spelt *Bodicca*, *Boudicca*, and, in Fletcher's tragedy, *Bonduca*), 'the British warrior-queen,' wife of Prasutagus, king of the Iceni, a tribe in what is now Norfolk and Suffolk. On the death of her husband about 60 A.D., the Romans seized her territory, and treated the inhabitants with the most brutal cruelty. The queen herself was scourged, her daughters were outraged, and the noblest among the Iceni were treated as slaves. Boadicea, roused to fury by her wrongs, gathered round her a large army, destroyed the Roman colony of Camulodunum (Colchester), took Londinium and Verulamium (London and St Albans), and put to death, according to Tacitus, as many as 70,000 Romans. Suetonius Paulinus, the Roman governor of Britain, who had been absent in Mona (Anglesey), now advanced against the queen, and with not more than 10,000 men inflicted an overwhelming defeat on an enemy twenty times as numerous. The British loss is said to have been 80,000, the Roman only 400. Boadicea, overwhelmed with despair, killed herself by poison. Her story is best remembered by the noble poems of Cowper and Tennyson.

Boar, WILD (*Sus scrofa*), a non-ruminant, even-toed hoofed mammal, with conical teeth (Ungulata, Artiodactyla, Bunodontia). The family (Suina) to which the boar belongs, and which also includes the river-hog, the babiroussa, the wart-hog, the peccari, &c., is characterised by the pointed head with familiar pig-snout, large ears and small eyes; by the thin legs, often curled tail, bristly hide; by the four toes on fore and hind feet, of which only the two inner reach the ground; by the prominent canines, especially in the males. They are also notorious for their voracious omnivorous diet, love for damp places, and rapid multiplication.

The wild boar is a large powerful beast, measuring 4 feet or more in length, with very strong and formidable canine teeth in the male. The head is more elongated than that of the domesticated form. The strong bristles are blackish-brown, mingled with yellow, and these, along with the brownish-gray under-hair, give the animal a dark grayish-brown colour, often approaching black.

Wild Boar.

The young ones are yellowish for six months, and have white and brown stripes or spots. The adult males usually live alone, but the female is accompanied by her family, and sometimes by other sows and families. Four to six young are born in a litter. The boars come from their places of concealment at night; they devour all sorts of things, but especially vegetable produce. The sense of smell is acute, and they do not miss much of what they rout up. By their voracity and ruthless grubbing they do great damage to crops and to young trees. On account of this, as well as for the sake of their flesh and bristles (q.v.), they are much hunted in the regions where they occur, and the fury of the enraged male, and the zeal of the sow in protecting its young, add a spice of danger to the chase. In some parts of India 'pig-sticking' is the chief sport. Many species of *Sus* have been distinguished, but four or five alone are certain: *S. vittatus*, 'from Sardinia to New Guinea, from Japan to Damaraland (South-west Africa); *S. verrucosus*, from Java and Celebes; *S. barbatus*, from Borneo; and *S. scrofa*, formerly common throughout temperate Europe and Asia. At Chartley, in Staffordshire, the wild boar was not extinct so late as 1683; and at Sydnope, in Derbyshire, Alpine boars and sows, introduced from the Continent, bred between 1823 and 1837, when the last was shot. The wild boar is still common in woody damp regions in some parts of the Continent.

Fossil species occur in the Miocene and Pliocene strata. Hyotherium is abundant in the upper Eocene and Miocene ages. The oldest representatives are *Eohyus* and *Achanodon* (Parahyus?) from the lower and middle Eocene, the former

'with at least four functional toes, and with certain peculiar carnivore modifications of the skull.'

A boar's head, served up as the most important dish on the baronial table, was the subject of many a carol and poetical allusion connected with Christmas festivities in England. The boar's head (see HERALDRY) is a well-known cognisance. For the wild boar's tooth, see also BABIROUSSA; for swine in domestication, see PIG.

In hunting the boar, any and every large and powerful kind of dog has been used, those with rough coats being preferred, as being less liable to severe injury from the boar's tusks. But the name BOARHOUND is generally given in England to the breed also known as Great Dane, Ulmer Dog, Deutscher Dogge or German Mastiff. It is a strong, handsome dog, which may reach thirty-three inches in height at the shoulder, carrying the head and neck high, with prick ears. It unites the strength of the mastiff with the elegance of the greyhound. It hunts chiefly by sight, but is usually a kindly, companionable dog, and is in Britain rarely employed in the chase. The hair is short, hard, and dense, the colour various shades of gray ('blue'), red, black, or white, with patches of the other colours.

Boarding is the name for an attack by one vessel on another, a company of armed men from the one forcing their way on board the other. In the days of ironclads, boarding of war vessels is less frequent than of old. See TACTICS (NAVAL). A *boarding-net* is a framework of stout rope-netting placed so as to obstruct boarders.

Boarding-out System. See POOR-LAW

Boardman, GEORGE DANA, Burmese missionary, was born in the State of Maine in 1801, and educated at Andover. Ordained in the Baptist Church in 1825, he sailed the same year to the East Indies, and after mastering Burmese, began his labours at Maulmain in May 1827. He had great success, especially in his preaching tours; but the severe strain soon broke down his health, and brought on his death early in 1831. His widow married the more famous Burmese missionary, Judson.

Board of Trade. See TRADE. For other boards, see WORKS (BOARD OF), EDUCATION, POOR-LAW, &c.

Boar-fish (*Capros*), a genus of fishes in the

Boar-fish (*Capros aper*).

Carangidæ or Horse-mackerel family of Acanthopterygii or bony fishes with spinous rays. The protrusible mouth presents a resemblance to a hog's snout as the name suggests. The body has an oval compressed form like that of the related John Dory, from which it differs conspicuously in the absence of spines at the base of dorsal and anal fins, and of long filaments on the dorsal spines. The common Boar-fish (*C. aper*) is a well-known

inhabitant of the Mediterranean, rarely caught on the coasts of England. The eyes are very large, and placed far forward; the body is of a carmine colour, lighter below, and with seven transverse orange bands on the back.

Boarhound. See BOAR.

Boat is the name applied to a small open vessel, used for conveyance on water. Boats differ very considerably at various parts of the coast, and in the different countries of the world, being usually adapted to the nature of the waters and the conditions of the service in which they are employed. They may be lightly or strongly built; flat-bottomed or round; bulky in form for carrying, or long and small-bodied for speed; of little draught where the water is shallow, or of great draught for deep water. Boats are built plainly for commercial purposes, and are highly finished, even ornamental, for pleasure. They are usually propelled by oars or sails, but, since the beginning of this century, motors are gradually displacing manual power.

The earliest boats were very primitive. First, there was a rude *raft*, formed by binding tree-trunks together; then the *dug-out*, made from a tree-log hollowed out and roughly shaped at both ends. These were used in various countries, including our own, and some ancient specimens are still preserved. Both types are still not unknown, and from these the modern boats—flat-bottomed, and round—have gradually been developed. At an early date there was the rudimentary structure, built with wooden laths, covered with skins or canvas, and smeared over with pitch to make the boat watertight. Such was the small *coracle* of the ancient Britons, which could be carried by a man on his back. Or the covering might be the bark of trees sewn together and made watertight with gums, like the Indian *canoe* of North America. Similar types of boats appear to have been produced in countries far apart and between which there was apparently no communication. The only reason to account for this would seem to be that similar wants and conditions had to be contended with, and there was a similar lack of materials and appliances to produce anything better.

Coming to modern times, there are many cases of similarity in types produced in various parts of the world. The *canvas boats* used by the Galway fishermen are long and narrow. Though as much as 20 feet in length, one of these boats can be carried by one man. They have a crew of four men, each man using a pair of short oars. They have many of the characteristics of the *surf-boat*. Then the flat-bottomed *sharpie* (fig. 1) of

Fig. 1.—Sharpie.

Connecticut is of somewhat similar type to the Chinese *sanpan* and the Wexford *cof*. Again, the *sneak-boat* of New Jersey, which has a spoon-shaped bow, bears a resemblance in many ways to the old Irish *canoe* of Kilkee and the Norwegian *pram*.

Before the days of steam power, the largest and strongest boat carried on board a ship was the longboat. And, for a long time, the royal navy set the pattern for the boats in the merchant service, and on the coast these were copied. But the introduction of steam brought about the extinction of the largest boats propelled by oars. The steam-launch then became the largest boat carried by a

warship, and is longer and more nearly flat-bottomed than the longboat was.

Typical boats used in the navy are as follows: *Steam-launch*.—42 feet in length, by 11 feet 6 inches beam, and 4 feet 6 inches depth; carvel built, of double skin teak laid diagonally. *Steam-pinnace*.—36 feet in length, by 10 feet 3 inches beam, and 3 feet 6 inches depth; carvel built similarly to the launch. *Steam-cutter*.—Varying greatly in size, but a lighter boat than a pinnace; carvel built in similar fashion. One of 30 feet length would be 8 feet beam, and 2 feet 8 inches depth.

On battleships, steam-launches burning coal are still preferred, because they are less likely to be set on fire than motor-boats with petrol or paraffin fuel. But on light-cruisers, destroyers, and other small craft, *motor-launches* are used. The motors usually run on paraffin fuel, but start on petrol.

Typical navy boats used for rowing are as follows: *Gig*.—A long, narrow, light boat, with six or eight oars; 30 feet in length, with a beam of 5 feet 6 inches, and 2 feet 2 inches depth; clench built, of elm. *Whaler*.—A sharp-sterned boat, with good sheer, having six oars, also sails; 27 feet in length, by 5 feet 6 inches beam, and 2 feet 2 inches depth; clench built, of elm. *Dinghy*.—The smallest boat, from 12 to 14 feet in length, 4 feet 8 inches beam, and 2 feet 2 inches depth; can be rowed by one man; clench built, of elm. For destroyers, a *light whaler* is built, clench fashion, of yellow pine, 25 feet in length, 5 feet 6 inches beam, and 2 feet depth, and has four oars. A *light dinghy* is also built, clench, of yellow pine, 16 feet long, 4 feet 6 inches beam, and 1 foot 10 inches depth. *Canvas Berthon boats*, which are collapsible, are also supplied for destroyers. All these boats, except the whalers and the Berthon boats, have transom sterns.

The boats around our own shores are infinite in variety, but only a few typical ones can be mentioned here. On the Thames there is the waterman's skiff or wherry (fig. 2). This is a lightly

Fig. 2.—Thames Wherry.

built boat, as the water is sheltered and smooth. At many places somewhat similar boats are used, but of stronger build and modified proportions where there is exposed water, and beaching necessary. At almost every place on the coast a square-sterned boat of this sort is much in use, about 14 feet in length, with three thwart, and the seats in the stern. At Portsmouth the waterman's boat is sharp-sterned like a whale-boat, and is admirably adapted for broken water, the sea there being very short and steep, with an east wind on an ebb tide. These boats are larger—up to 25 feet in length—and also carry a mainsail, mizzen, and jib. The

Fig. 3.—Coble.

fishing-skiff on the west coast of Scotland is also a sharp-sterned boat, for similar reasons, but is

rigged differently, having a lugsail and jib. On the north-east coast of England a peculiar, long, flattish-bottomed boat is in use by the fishermen, called a 'coble' (fig. 3). The particular form is adopted because this boat is beached stern first in surf, and the high, sharp, flaring bow is designed to meet the dangerous seas on that coast. The draught aft is very shallow; and as these boats are sailed, the peculiarly deep rudder and the fore-foot check the tendency to make leeway. This type of boat is reported to be excellent in bad weather, and is built from 15 feet to 40 feet in length. By way of contrast, in some parts of the western isles of Scotland, such as Barra, the boats in favour are almost V-shaped in cross section; so also are the very primitive boats of Fair Isle, between Orkney and Shetland.

On inland waters there are some very light boats used for pleasure. The punt on the upper Thames is a long, flat-bottomed boat, propelled by a pole. Then there is the Thames skiff or randan (fig. 4),

Fig. 4.—Randan.

a very popular rowing-boat, usually built of cedar or mahogany, from 20 to 40 feet in length. These boats are very finely finished. On inland lakes, such as Windermere, a somewhat similar type of boat is found.

Every merchant vessel is required by law to carry a sufficient number of boats to accommodate all

in large yachts there may be one or two launches, but a steam-launch is now seldom seen. They are generally driven by petrol motors, these being much handier than paraffin motors, and, the boats being open, there is little danger, if proper precautions are taken. The most important boat on a large yacht is the lifeboat. This boat is similar to those in the merchant service, though there are often modified arrangements. A very useful yacht's boat is the cutter, lighter than the lifeboat, and without flotation cases. This boat is used by the crew for the general work of the ship. The dinghy is the smallest boat carried, being from 8 to 16 feet in length. Yachts' boats are not under Board of Trade jurisdiction.

Motor-boats.—The introduction of the marine motor early in this century has gradually revolutionised the small boat. The motor is taking the place of manual power in almost every class. A portable motor can even be attached to a small dinghy or other very light boat. Whether it be a shore boat for pleasure, a harbour boat, a fishing boat, or a ship's boat, the motor is found on board, and it seems likely that very soon the great majority of boats will be motor driven. The petrol motor is most generally used, but paraffin fuel motors are adopted in certain classes of boats.

For Racing-boats, see ROWING.

Boat-building.—The design is prepared on paper, and then transferred to the floor of what is termed a 'mould loft,' and made full size. From this full-

Fig. 5.—Lifeboat.

persons on board. These vary considerably in type. Pontoon lifeboats have collapsible bulwarks, and may be stowed one above another; there are also rafts; but the most serviceable lifeboat is the 'open' type (fig. 5). This boat, in large vessels, is usually 28 feet in length, and has flotation cases

size drawing, wood moulds of the cross sections are made, as shown by fig. 7, with a notch to fit over the keel. The stem, stern-post, and keel are cut out to the required shape, and scarphed and fastened together. This part of the structure is then fixed on building-stocks, consisting of blocks of wood, or a 'deal' secured edgewise in a horizontal position on uprights. The stem and stern-post are further temporarily connected at their upper ends by a fore-and-aft batten of wood, and

Fig. 6.—Four-oared Racing-boat.

all along under the side seats, so that she may float, with all on board, even if filled with water. The lifeboat is a rowing-boat, carrying also sails—usually a lugsail and jib. The construction and equipment of boats for the merchant service must comply with the Board of Trade regulations. Large passenger vessels are now carrying motor-boats, though not compelled to do so. The Board of Trade, however, insist that the motor runs on paraffin fuel, though it may be arranged to start on petrol. These motor-boats are not intended to take the place of lifeboats, but are meant to tow a number of lifeboats in case of disaster to the vessel. Wireless apparatus is sometimes carried by these motor-boats.

Yachts' boats are generally similar to those on merchant vessels, but are very highly finished and much lighter in construction. A gig is never used now, the owner's launch having taken its place.

they are also held in position on the stocks by struts extending to the floor and to the beams in the roof of the building-shop. The stern-board or transom, and the moulds of the cross sections, are then fitted and secured in their proper places. The moulds are further secured by bands of wood called 'ribbands,' temporarily bent round on the outside. The moulds and the stem and stern-post are marked (see *b, b, b*, fig. 7) to represent the widths of the planks, which

Fig. 7.—Mould

are about 5 inches, including $\frac{3}{4}$ inch overlap in 'clencher-built' boats termed the landing (fig. 10).

The bottom plank, called the garboard strake, is first fitted truly into a rabbet, or groove, cut in the keel, stem, and stern-post to receive it, and it is nailed at intervals of about 3 inches. The next plank is then held over the upper edge of the garboard strake, and marked round with a pencil. This plank is removed and sawn through along the pencil line, the overlap being allowed for. The upper edge of this plank is then cut to the right width to fit the marks, *b, b*, on the moulds, stem and stern-post, and it is planed and the edges bevelled to fit round the curve of the moulds. The plank is held in position by a series of wooden clamps, set up by wedges, as shown in fig. 8.

Fig. 8.—Clamps.

The edges of the plank are then fastened together at intervals of about 3 inches, the nails being put in from the outside, and clenched on the inside on rooves (small copper rings). When all the planks are on and fastened together, the timbers, or ribs, are put in, about 6 inches apart. These are usually made of American elm on account of its straight grain, flexibility, and toughness. The ribs, having been cut to the required size, are put into a long box supplied with steam from a boiler, and are kept there until they are sufficiently pliable to be easily bent round the bilges of the boat inside without injuring them—in one piece, passing over the top of the keel. The planking is now nailed to each timber, the nails being put in from the outside through the landings, and clenched on rooves on the inside of the timbers. The timbers are also fastened to the keel. After all the timbers have been fitted and nailed, the 'inwales,' or gunwales, are fitted over their heads, and nailed and rooved to the gunwale strake, and connected at the forward end by a breast hook, and to the transom by knees at the aft end. A bearer or stringer is fitted round the boat inside, to take the seats or thwarts, the latter being further secured to the sides of the boat by knees extending to the gunwales.

Fig. 9 shows in detail the construction of a clencher-built boat. Oak-knees, termed floors, are

Fig. 9.—Construction of Lifeboat.

fitted alongside the timbers, and these are particularly necessary when the bottom of the boat is so sharp that the timbers cannot be bent round over the keel. In a carvel-built boat the surface is smooth, the edges of the plank meeting, as shown

by fig. 11. The seams are generally caulked with oakum or cotton, and payed with marine glue or putty. But in boats where carvel planking is thinner, close or 'tub' jointed seams are adopted

Fig. 10.
Clencher.Fig. 11.
Carvel.Fig. 12.
Tub-jointed
Carvel.Fig. 13.
Ribband
Carvel.

(fig. 12). Light racing-boats and canoes are carvel-built, but the plank is too thin to admit of caulking, or of tub-jointing, and a strip of wood is worked over the seams inside. The construction is then termed 'ribband' carvel (fig. 13). Another system of carvel planking is the 'double diagonal.' This gives great strength and lightness for boats such as launches and lifeboats. The two thicknesses of planking are wrought across each other at right angles, and are fastened together (with calico between) as well as to the framing.

Boat-lowering and Disengaging Gear is the system of ropes, blocks, and davits or cranes, by which ships' small boats are lowered to the sea, and sent clear of the fastenings. In the early history of shipping, no proper means were employed for launching boats; but as the passenger-carrying trade developed, vessels were built having davits with blocks and falls, or tackle. The first davits were fixed wooden uprights at the sides of the ship; then hinged wooden uprights called 'topping davits;' then curved iron, fitted in sockets, but capable of turning round. The last-named method is still the one most often adopted; but iron davits, hinging in a somewhat similar manner to the old wooden topping davits, have been fitted within recent years.

Until comparatively recent times, the almost universal mode of attaching boats to the falls and blocks was by an eye on the bottom of each lower block, which engaged with a hook fixed near the bow and stern of the boat. Many calamities befalling boats when being launched in the hurry and excitement of shipwreck or other emergency at sea have led to the adoption of means for quickly disengaging them from the lowering tackle, and for regulating the process of lowering as well. The first recorded invention of an improvement for lowering and disengaging boats was in 1830; and since that time there has been a plentiful list of devices. But although many apparatus have been designed to accomplish the safe lowering of boats, the commonest practice, as stated, is to employ the plan of simple block and falls.

Some recent methods for disengaging ensure that a boat suspended from the falls cannot be unhooked or released until entirely water-borne, and all strains taken off the falls.

Fig. 14 shows one type of disengaging hook in position, with the boat suspended. Fig. 15 shows

Fig. 14 —Boat Suspended.

an enlarged view of another type of hook, with the boat suspended. When the fore-and-aft line, reaching from tumbler to tumbler and holding them up, is allowed to slack, the tumblers drop and allow the hooks to swing back on their pivot (see fig. 16),

Fig. 15.—Hook Engaged.

Fig. 16.—Hook Released.

thus freeing the blocks and tackles. The fore-and-aft line is under control of the coxswain, and by keeping the line hand-taut while the boat is being lowered, there is no possibility of the boat disengaging itself should one end of it touch the water before the other. Even when the boat is completely water-borne, the hooks of themselves cannot become disengaged, unless as the result of a slackening of the line.

Boat-plug is a wood, cork, or metal stopper, fitted in a socket through the bottom of a boat, to drain away the water which may have been shipped or have leaked in while the boat was in use, or rain-water. The Board of Trade require that each boat shall have two plugs—one a spare one—both to be attached to a fixed part of the bottom by lanyard or chain.

Boatbill (*Cancroma cochlearia*), a bird of the Heron (q.v.) family, the only known species of a genus differing from the true herons in little else than the form of the brown bill, which is comparatively short and very broad, the mandibles resembling the bowls of two spoons placed one upon the other, the upper mandible overlapping the lower, keeled on its upper ridge, and hooked at the point. The boatbill is about the size of a domestic fowl, has shorter limbs than most of the herons, but resembles them in plumage, and is abundantly provided on the back of the head and neck with

elongated feathers, which it erects when irritated. The front parts are white (the crown black in the male), the upper surface and tail whitish gray, the

Boatbill (*Cancroma cochlearia*).

under side yellowish white, the belly rusty red. It inhabits Cayenne, Surinam, Brazil, &c., sits perched upon trees which hang over streams, and darts down upon fish, which seem to be its principal food.

Boat-fly (*Notonecta*), a genus of insects of the order Hemiptera (q.v.), sub-order Heteroptera, and family Hydrotidae, or Water-bugs (q.v.). The English name well describes their boat-like form, eminently adapted for progression in water. They have the peculiar habit of always swimming on their back, and of resting in this posture suspended at the surface of the water. Their hindmost legs are very long, and when these are thrown out at rest the insect looks like 'a waterman resting on his sculls.' One species, *N. glauca* (sometimes called the *Water Boatman*), is common

Water Boatman (*Notonecta glauca*).

in Britain and throughout Europe; it is about half an inch long, and varies considerably in colour; but exhibits a general greenish tinge, the other colours being black, brown, and gray. They fly well, but seldom use their wings. They move with difficulty on dry ground, and prefer to keep to quiet water. When they descend into the water, they carry down a supply of air in a hollow between their folded wings. They feed voraciously on animal substances, often kill and devour those of their own species, and are said to do damage among fish-spawn. There are many species, but only two are European. An allied genus (*Corixa*) swims in the normal fashion, and is represented in almost every quiet pool.

Boat-lowering and Disengaging Gear. See BOAT.

Boatman. See BOAT-FLY.

Boat-racing. See ROWING.

Boatswain, the officer on board ship who is responsible for the efficiency of the boats, sails,

rigging, cables, anchors, flags, cordage, and generally stores in connection with these. In the navy he is a warrant-officer, and is immediately under the navigating officer in some of these duties. He also keeps account of all the spare rigging, &c., and superintends the replacement of old by new. He assists in the necessary business of the ship. There are signal boatswains, torpedo boatswains, and boatswains for quarter-deck duties. Boatswains' mates are petty officers or leading seamen who assist the boatswain, and 'pipe' orders with a boatswain's whistle or 'call.'

Boavista, the easternmost island of the Cape Verde group. Very arid, it produces salt and orchil. Area 240 sq. m.; pop. 3000.

Bobadilla, FRANCISCO, the Spanish commander appointed to supersede Columbus as viceroy of the Indies, who sent Columbus home in chains. Having utterly mismanaged matters, he was recalled from Hispaniola under arrest, and drowned on the way to Spain (1502).—The use of 'Bobadil' as a braggadocio comes from the blustering captain in Ben Jonson's *Every Man in his Humour* (1598).

Bobak, or BOBAC (*Arctomys bobac*), a species of Marmot (q.v.) ranging (now or lately) from Poland to eastern Siberia.

Bobbin, TIM. See COLLIER (JOHN).

Bobbin-net. See LACE.

Bobbins are small wooden reels or rollers, flanged at the ends, and bored through the centre lengthwise, so that they can be placed on a spindle or skewer. The bobbin or pirn on which ordinary sewing-thread is wound, although generally of small size, is a good example of their prevailing shape. Bobbins are used in the spinning processes for cotton, flax, wool, and silk, and are of various sizes, the largest being generally those used for the slubbing frames where the cotton, for example, first passes from the lap shape given by the carder into a loose kind of strand. After this the bobbins diminish in size for the various succeeding stages to the finished yarn. A 'slubbing' bobbin may be 15 inches long and 5 inches in diameter at the flange, but one or two exceptional kinds are larger than this. For special purposes, such as lace-making, the bobbins used are quite unlike the ordinary kinds. These and some other varieties are made of metal. Paper tubes are now largely adopted in certain cases where bobbins were formerly employed. Bobbins are made of birch, beech, ash, and plane tree, and machinery for their manufacture has been erected here and there in the Highlands of Scotland and other wooded parts of the country. But they are also largely made of American and other foreign woods, as well as from native material, in factories in Lancashire and Yorkshire. Ingenious automatic machinery is now employed, especially for making the smaller sizes. It will be readily understood that bobbins are used in enormous numbers wherever there are large spinning-mills.

Bobbio, a Lombard town, 3 miles SSE. of Pavia, near the confluence of the Bobbio and the Trebbia. Bobbio originated from a monastery founded here in 612 by St Columbanus (q.v.), whose famous library has mostly found its way to the Vatican. Since 1014 it has been the seat of a bishopric. Pop. 5000.

Bob-o-link, or BOBLINK, REED BIRD, or RICE BIRD (*Dolichonyx oryzivorus* or *Icterus acipennis*), a common American bird found from Paraguay to Canada, the only one of its kind, and that difficult to classify. Some place it near the Baltimore bird (*Icterus*), others near starlings, but both the characteristics and the character of the bob-o-link exhibit much that is unique. The beak is short

and straight; the nostrils surrounded by a fold of skin; the wings are long, especially in their first feather; the tail-feathers are stiff-pointed. The

Bob-o-link.

plumage is unusually conspicuous for a ground bird. In the male the head, lower surface, and tail are black, while the upper surface is lighter, yellowish white in front, black with yellow streaks behind. The colour and the note change with the seasons and with the functions of the bird. The female is much plainer—yellowish brown with darker streaks above, and pale grayish yellow below.

The name—originally *Bob Lincoln*—is an imitation of the bird's note. In song, the full-throated male bob-o-link is unique, rivalling the lark, imitable by the mocking-bird, 'in qualities of hilarity and musical tintinnabulation,' according to Burroughs (*Birds and Poets*), quite unequalled. His volubility borders on the burlesque. In disposition also the male is interesting; he affords the 'most marked example of exuberant pride, and a glad, rollicking, holiday spirit, that can be seen among American birds.' His love-making emotions appear to be unusually strong, as strong indeed as his Quaker mate is shy, retiring, and indifferent. The change of the male in colour and form at the breeding time is very striking. He becomes black and white more emphatically, so as sometimes to be called the 'skunk bird,' and acquires a broad form and a curious 'mincing gait.' Robert o' Lincoln becomes 'an ornithological coxcomb' of the highest order. He sings on brier and weed, or jerking up and down in the air, while his mate may be brooding in a simple nest among the grass. The bob-o-link is said to exhibit the common trick of seeking by exaggerated fuss in some other quarter to lead intruders away from the nest.

The bob-o-link is a bird of passage, spending the winter in the West Indies. In summer it is found as far north as the banks of the Saskatchewan, in 54° lat., but is most plentiful in the Atlantic states and other eastern parts of America, where it is to be seen in every meadow and cornfield. It renders good service by the destruction of insects and their larvæ; but in the South, both in April and August, at seed-time and harvest, its ravages seriously cripple the rice-growing industry, and destroy about a fourth of the crop. Thousands of men and boys are then employed to shoot the trespassers, who are killed in great numbers for the table; their flesh is delicate, and resembles that of

the ortolan. On account also of their beauty and powers of song, many are caught, caged, and sold in the New York and other markets.

Bobruisk, a town of White Russia, on the Beiesina, 87 miles S.E. of Minsk by rail, with a large trade in wood and corn. It was besieged ineffectually by the French in 1812, and was made a fortress of the first rank by the Emperor Nicholas. Pop. 40,000 (very many of them Jews).

Bocage, MANOEL DU (1766-1806), a great Portuguese poet. See PORTUGAL.

Boca Tigre (also Bocca Tigris, and in English Bogue), the Portuguese translation of the Chinese name *Hu-mun*, 'tiger's mouth,' given to a portion of the estuary of the Canton River (see CANTON). On its rocky islands are situated the Bogue forts, which have been more than once captured by the British.

Boccaccio, GIOVANNI, was born either at Paris or at Florence in 1313. He was the illegitimate son of a merchant of Certaldo, and at the age of ten was apprenticed to a merchant of Paris. Disliking commerce, he attempted but quickly abandoned the study of canon law, and was then sent by his father to Naples, with the intention that he should follow a mercantile career. At Naples he gave himself to story-writing in verse and prose; mingled in courtly society; and fell in love with the lady whom, under the name of Fiammetta, he made well-nigh as famous as the Beatrice of Dante and the Laura of Petrarch. In the *Filicopo* she is said to have been an illegitimate daughter of King Robert of Sicily; in the *Fiammetta* she is represented as a beautiful Neapolitan, of noble but not of royal descent. She appears in a number of Boccaccio's works, and is one of the story-tellers in the *Decameron*. Up to the year 1350 Boccaccio lived alternately at Florence and at Naples. Between 1340 and 1350 he produced the prose tale of *Fiammetta*; the *Ameto*, a pastoral piece; and the *Amorosa Visione*, in which he sang the praise of his mistress in *terza rima*. To the same period belong the *Filicopo*, the *Teseide*, and the *Filosttrato*. In the *Filicopo* the story of *Flora et Blanchefleur*, one of the finest of the French 'Romans d'Adventures,' is cast into prose and embroidered with fanciful rhetoric, but is hardly improved in the retelling. The *Teseide* is a graceful version in *ottava rima* of the mediæval romance of Palamon and Arcite, the same story as forms the subject of Chaucer's *Knight's Tale* (a poem which is to a great extent translated from Boccaccio's), and of Shakespeare and Fletcher's *Two Noble Kinsmen*. The *Filosttrato*, which is likewise in *ottava rima*, deals with the loves of Troilus and Cressida, a story which had become widely popular in various forms after the appearance in 1287 of Guido of Messina's Latin romance of Troilus and Briseis. The heroine's name was changed by Boccaccio, from whose poem Chaucer translated nearly half of his *Troilus*. The year 1350 may be taken as the beginning of a new period in Boccaccio's life. Until then it is a life given to song and love and adventure. Thenceforth, for some fifteen years, it is the life of an honoured citizen, of a diplomatist intrusted with important public affairs, of a scholar devoted to the cause of the new learning. During this period, in which he formed a lasting friendship with Petrarch, Boccaccio, as Florentine ambassador, visited Rome, Ravenna, Avignon, and the court of the Margrave of Brandenburg. In 1358 he completed his great work, the *Decameron*, which he had begun some ten years before. In 1360 he lodged in his house the wandering Greek scholar, Leontius Pilatus, whom he persuaded the Florentines to appoint to a Greek professorship, and by whose aid he was enabled to transcribe and forward to Petrarch prose

versions of the *Iliad* and the *Odyssey*. He for some time held a chair founded for the elucidation of the works of Dante, on whose *Divina Commedia* he produced a commentary, now mainly interesting from the light which it sheds on Florentine life in the 14th century. During his last years he lived principally in retirement at Certaldo, and would have entered into holy orders, moved by repentance for the follies of his youth, had he not been dissuaded by Petrarch. He wrote in Latin an elaborate work on mythology, *De Genealogia Deorum*, and treatises *De Claris Mulieribus*, *De Montibus*, &c. He died at Certaldo on the 21st December 1375.

Boccaccio ranks among the great writers of Europe in virtue of the prose tales of the *Decameron*. This famous book opens with a description of the plague at Florence in 1348. Seven ladies and three gentlemen are introduced, who leave the city and betake themselves in quest of security and distraction to a country villa. There they while away ten days (whence the name *Decameron*) by each in turn telling stories in the garden. In all, one hundred tales are thus told. Many of these are extremely licentious; others are full of pathos and poetical fancy; several are masterpieces of imaginative creation; all are related in exquisitely graceful Italian. Boccaccio selected the plots of his stories from amid the floating popular fiction of the day, and especially from the *fabliaux* which had passed into Italy from France. His originality lies in his consummate narrative skill, and in the rich poetical sentiment which transforms his borrowed materials. The influence of his great book upon European literature has been wide and profound. Among his countrymen, by whom he has been generally accepted as an almost incomparable master of Italian prose, he has found many imitators, the most notable being Firenzuola, Bandello, Cinthio, and Grazzini. In France the transformation of the *fabliau* into the *nouvelle* was partly due to the example set by Boccaccio. His influence is apparent in such collections of tales as the *Cent Nouvelles Nouvelles* ascribed to Antoine de la Salle, the *Grand Parangon de Nouvelles Nouvelles* of Nicholas of Troyes (1535), and the *Heptameron* (1558) of Marguerite of Navarre. Several of Boccaccio's stories are versified in the *Contes* of La Fontaine, in whose hands they assume a close resemblance to the form under which, as *fabliaux*, they had crossed the Alps into Italy. The debt of English writers to Boccaccio begins with the translations in Chaucer's *Troilus*. In the *Canterbury Tales* the stories told by the Reeve and the Franklin, and the story of Patient Griselda, are founded either on stories in the *Decameron* or on the same *fabliaux* as had been recast by Boccaccio. Sidney's *Arcadia*, says Mr Symonds, 'is a copy of what Boccaccio had attempted in his classical romances.' Cyril Tournour's *Atheist's Tragedy*, Marston's *Parasitaster*, and Fletcher's *Women Pleased*, are examples of plays of which the plots were taken, wholly or partly, from Boccaccio. The scene of the caskets in the *Merchant of Venice* corresponds to a story in the *Decameron*. The plot of *All's Well that Ends Well* is taken from Boccaccio's story of Giletta and Beltramo, and the plot of *Cymbeline* is partly drawn from the ninth novel of the second day. None of Dryden's works have had more enduring popularity than his *Tales from Boccaccio*. In later days, Keats (in *Isabella*), Tennyson (in *The Falcon* and *The Lover's Tale*), Longfellow, Swinburne, and George Eliot are among those who have turned for their subjects to the deathless pages of the hundred tales.

Apart from the narrative interest and beauty of conception which mark its finest stories, the salient feature of the *Decameron* is the contrast between

the subjects and the style. The matter is medieval, while the form is classical. Boccaccio collected much that was choicest and most typical in the popular fiction of his day, and handed it down to modern times enshrined in imperishable language. The two great tendencies which run through European literature, the classical and the romantic, are seen working together in the *Decameron* as they are hardly to be seen elsewhere. The stories retain their medieval colour and flavour; yet the style preserves the classic dignity and elegance, the classic disdain of unessential detail. Despite the delicacy of many of the novels, the impression left by the book as a whole is neither one of frivolity nor of grossness. The satiric malice and reckless levity of the *fabliaux* are replaced by a voluptuous melancholy, a refined pensive epicureanism. 'The central idea of the book,' says M. Emile Montégut, 'is that of love, represented as the chief motive force in social life, and the sovereign of the world. Love takes the place which fate held with the ancients, and which free-will holds among Christians.' The same fine critic maintains that the tales have been carefully linked in the order best suited to enforce this central conception. Whether or not they were so arranged, the frame in which they are set is a masterpiece of literary art. The impressive account of the plague at Florence—the description of the burning noon-day calm, which recalled to Ampère the opening of Plato's *Phædo*—the contrast which haunts the reader throughout the book, between death ravaging the world outside, and the quiet garden with its graceful inmates engrossed in song and story—the poetical fancy which invests Fiammetta and her companions with an undying charm—to these things there is no parallel in the works of Boccaccio's followers, as there is none to the golden perfection of his style.

See Italian lives by Baldelli and Tiraboschi; German by Landau and Koerting; English by Hutton (1909); Bartoli, *I Precursori del Boccaccio*, studies by Crescini (1887), J. A. Symonds (1894), Lee (1909).

Boccage, MARIE ANNE FIQUET DU (née Le Page), a French poetess, once famous, now almost forgotten, born at Rouen, 22d October 1710. She published a small volume of verse in 1746; next an imitation of Milton, *Paradis Terrestre*, in 1748; and in 1756, her most important work, *La Colombiade*. Her letters to her sister, written while travelling through England, Holland, and Italy, are her most interesting work. During her lifetime she was excessively bepraised by men so great as Voltaire and Fontenelle; but modern readers cannot help thinking that her beauty must have recommended her verses. She was elected member of many learned academies, and died 8th August 1802.

Boccherini, LUIGI, composer, born at Lucca, 14th January 1740, studied at Rome, and appeared with great success at Paris in 1768. He next went to Madrid, and became chamber-composer to the Infante Don Luis, afterwards holding the same post under Frederick-William II. of Prussia. With the king's death in 1797, however, Boccherini's salary ceased, and the remainder of his life was darkened by poverty and ill-health. He died at Madrid, 28th May 1805. He wrote three hundred and sixty-six instrumental works, mostly trios, quartets, and quintets for strings, in which the cello is prominent; of his vocal works, a *Stabat Mater* for three voices has been published. Melodious, dignified, and displaying great originality, his best works are still esteemed.

Bochart, SAMUEL, a learned Protestant divine, was born of a good family at Rouen in 1599. He very early exhibited a remarkable aptitude for learning languages, and after extensive studies,

especially in the Semitic languages, at Paris, Sedan, Saumur, and Leyden, was chosen pastor of the Protestant church at Caen. Here in 1629 he gained great reputation by his victory in a public discussion of nine days' duration over the famous Jesuit, Verin. In 1646 he published his *Geographia Sacra*, a work of marvellous erudition. In 1652 he went to Stockholm along with his disciple, Huet, on the invitation of Queen Christina. The court-life, however, did not suit him, and his visit was short. His great work, *Hierozoicon, sive de Animalibus Scripturæ Sacræ*, published in 1663, had afterwards the honour of being commended by Cuvier. He died suddenly, May 16, 1667. A complete edition of his numerous works was published at Leyden in 1712; and a new edition of the *Hierozoicon* at Leipzig, in 3 vols. (1793-99).

Bochnia, a town of Polish Galicia, 24 miles ESE. of Cracow by rail. Extensive mines of rock-salt employ upwards of 500 mineis. Pop. 10,000, a fourth of them Jews.

Bocholt, a town of Prussia, on the Aa, 13 miles N. of Wesel by rail, with manufactures of chicory, cotton goods, iron wares, and machinery; pop. 25,000.

Bochum, a town of Prussia, 35 miles NE of Düsseldorf by rail, a great centre of Westphalian industry. Steel ropes and cables, machinery, files, tubing, safety-lamps, coal-tar substances, tin, roofing-felt, bricks, oil, and carpets are among its manufactures. There are great coal-mines near. Pop. 143,000.

Bock, HIERONYMUS. See TRAGUS, BOTANY.

Böcklin, ARNOLD (1827-1901), a painter mainly of mythological subjects, was born at Basel, studied and worked in Germany and Italy, and settled finally near Zurich.

Bócland (i.e. book-land, or rather charter-land or deed-land), one of the early Anglo-Saxon forms of land tenure. Being proved by writing, it was distinguished from the Ethel, which had also been severed by an act of government from the Folcland (q.v.), and converted into an estate of perpetual inheritance, but which was proved by the pedigree of the owner and the witness of the community. It might belong to the church, to the king, or to a subject; it might be alienable and divisible at the will of the proprietor; it might be limited in its descent, without any power of alienation in the possessor. It was often granted for a single life or for more lives than one, with remainder in perpetuity to the church. It was forfeited for various delinquencies to the state, was exempt from service, except the *fyrd*, repair of bridges, and maintenance of fortifications.

Bode, JOHANN ELERT, astronomer, was born at Hamburg, 19th January 1747; in 1772 he became astronomer of the academy in Berlin, and in 1786 director of the observatory there. He published numerous astronomical works, including *Sternkunde* (3d ed. 1808), and *Uranographia* (2d ed. 1818), and founded the *Astronomische Jahrbücher*. He died 23d November 1826. The arithmetical relation subsisting between the distances of the planets from the sun, called after him Bode's Law, may be thus stated: Write, in the first instance, a row of fours, and under these place a geometrical series beginning with 3, and increasing by the ratio 2, putting the 3 under the second 4; and by addition we have the series 4, 7, 10, &c., which gives nearly the relative distances of the planets from the sun.

4	4	4	4	4	4	4	4	4
	3	6	12	24	48	96	192	384
4	7	10	16	28	52	100	196	388

Thus, if 10 be taken as the distance of the earth from the sun, 4 will give that of Mercury, 7 that of Venus, and so forth. The actual relative distances are as follow, making 10 the distance of the earth:

Mercury	Venus	Earth	Mars	Asteroids	Jupiter	Saturn	Uranus	Neptune
3.9	7.2	10	15.2	27.4	52.9	95.4	192	300

Close as is the approximate correspondence between the law and the actual distances, no physical reason has been given to account for it, although there is little room for doubt that such exists. Bode's law is therefore, in the present state of science, empirical. Kepler was the first to perceive the law, and Bode argued from it that a planet might be found between Mars and Jupiter, to fill up the gap that existed at the time in the series. The discovery of the Planetoids (see PLANETS) has proved the correctness of this prediction.

Bode, THE BARON DE, a baron of the Holy Roman Empire and not a British subject, though born in England of an English mother, claimed a share in the payment made by France in 1814 to indemnify British residents who had suffered by confiscation during the Revolution. The English government repudiated his claim in 1852. See CHILDE-Pemberton, *The Baroness de Bode* (1900).

Bode, WILHELM, art critic, and from 1889 director of the gallery at Berlin, was born in 1845, the son of a Brunswick member of the German Reichstag, and has written largely on Rembrandt and Dutch and Flemish paintings, Italian Renaissance sculpture, bronzes, furniture and carpets. His principal works have been translated.

Boden-See. See CONSTANCE, LAKE OF.

Bodenstedt, FRIEDRICH MARTIN VON, born in Hanover, 22d April 1819. In 1840 he went to Moscow as a tutor, and there translated Pushkin's poems. After extensive travels in the Crimea, Turkey, Greece, and Asia Minor, he returned to Germany in 1847, and published *Die Völker der Kaukasus* (1848). He edited a paper, was professor of Slav languages and of Old English at Munich, and from 1866 till 1873 superintendent of the Meiningen court theatre. He published many translations from the Russian, English (Shakespeare), and Persian, several volumes of poetry, and an autobiography. His *Lieder des Mirza Schaffy* (1851), feigned to be a translation from the Tatar, passed through nearly 150 editions within fifty years. He died in April 1892.

Bodichon, MADAME (1827-90; Barbara Leigh Smith, who, daughter of a Norwich M.P., married Dr Eugène Bodichon in 1857), was a water-colour painter, a founder of Girton College, and an advocate of women's rights.

Bodin, JEAN, a great political thinker of the 16th century, was born at Angers about 1530. After his studies in law at Toulouse, he settled in Paris. By Henry III. he was appointed king's attorney at Laon in 1576, and by the Duc d'Alençon he was carried as secretary to England in his journey to solicit the hand of Queen Elizabeth. In the States-general at Blois in 1576 Bodin asserted with great energy and eloquence the rights of the people and freedom of conscience. The later years of his life were spent at Laon, the inhabitants of which he was able to persuade to declare for the League in 1589, and for Henry IV. five years later. Here he died of the plague in 1596. Bodin's greatest work is *Les Six Livres de la République* (1576), of which the author issued a Latin version in 1586. According to Bodin, property and the family form the basis of society, and a limited monarchy is the best possible form of government. In opposition to certain contemporary Protestant writers on politics, he held that under no circumstances are citizens justified

in rebelling against their ruler. One prince, however, may interfere in behalf of the oppressed subjects of another. Bodin's book is the greatest of its kind published during the 16th century; yet it had but little influence on contemporary opinion. His *Methodus ad Facilem Historiarum Cognitionem* (1566) is considered by some writers as having laid the foundation of the true philosophy of history. His famous *Colloquium Heptaplomeres de Abditis Rerum Sublimium Arcanis*, left in MS., and indeed not published until 1857 by Noack, is a conversation between a Jew, a Mohammedan, a Lutheran, a Zwinglian, a Roman Catholic, an Epicurean, and a Theist, who come to the conclusion that henceforward they will leave off disputing on religion, and live together in charity and toleration. Bodin, though so broad and liberal in his opinions as to earn the reputation of an atheist, was not before his age in his notions about witchcraft, as is evidenced by his *Demonomanie des Sorciers* (1580). See H. Baudrillart's *Jean Bodin et son Temps* (1853); Renz, *Jean Bodin* (1905); and vol. i. of Flint's *Philosophy of History in Europe* (1874).

Bodle, an ancient Scottish copper coin of the value of two pennies Scots, or (about 1600) one-sixth of an English penny; said to have been so called from a mint-master of the name of *Bothwell*.

Bodleian Library, the public library of Oxford University, restored by Sir Thomas Bodley (q.v.) in 1598, his first act being the presentation of a large collection of valuable books, purchased on the Continent at an expense of £10,000. Through his influence and noble example, the library was speedily enriched by numerous other important contributions. Among the earliest subsequent benefactors of the Bodleian Library, which was opened in 1603, with a well-assorted collection of upwards of 2000 volumes, were the Earl of Pembroke, who presented it with 250 volumes of valuable Greek MSS.; Sir Thomas Roe; Sir Kenelm Digby; Robert Burton, author of the *Anatomy of Melancholy*; and Archbishop Laud, who made it a magnificent donation of 1300 MSS. in more than twenty different languages. Upwards of 8000 volumes of the library of the famous John Selden (q.v.) went to the Bodleian Library. General Fairfax presented the library with many MSS., among which was Roger Dodsworth's collection of 160 volumes on English history. The greatest benefactor in the 18th century was Dr Richard Rawlinson, who, dying in 1755, left his complete collection of books and MSS. to the Bodleian Library. The MSS. amounted to upwards of 4800. George Ballard, who died in the same year (1755), bequeathed to the library 44 MS. volumes of interesting letters, with other valuable MSS. During the nineteenth century the most important bequests were the collections of Richard Gough, on British Topography and Saxon and Northern Literature; the choicest books from the library of Edmund Malone, the editor of Shakespeare; and the valuable books, prints, drawings, and coins of Francis Douce; also a sum of £40,000, by the Rev. Robert Mason, the interest to be expended on books. By purchase, the library acquired some magnificent collections of Oriental, Greek, Latin, and Hebrew books and MSS. The Bodleian Library is particularly rich in biblical codices, rabbinical literature, and materials for British history. By the Copyright Act it is entitled to a copy of every book printed in the United Kingdom. The number of volumes it possesses is estimated at about 1,000,000, in addition to some 40,000 or 50,000 in manuscript. The first catalogue of the printed books was published by the first librarian, Dr James, in 1605; the last, nearly two centuries and a half later (1843-51), in 4 vols., by

Dr Bandinel, the eleventh who held the office since the institution of the library. In the interval, several catalogues of various departments of the library were published; and a supplemental volume was added by Dr Bandinel in 1851. By statutes drawn up for the government of the library by Sir Thomas Bodley, it was decreed that the vice-chancellor, the proctors, and the regius professors of divinity, law, medicine, Hebrew, and Greek, should be visitors and curators; a statute passed in 1856 added 'five more residents to be elected by congregation for ten years, if continuing to reside, and to be re-eligible.' Since 1861 the domed Radcliffe Library (now *Camera Bodleiana*) has served as a reading-room, and contains the books most commonly in demand. It was built to contain the library of the famous physician Dr John Radcliffe (q.v.) with money left by him for the purpose. The Bodleian contains, besides books, collections of 50,000 coins, of drawings, of models of temples and ancient buildings, of antiquities, and autographs, and a gallery of portraits. Literary men properly recommended are allowed to make extracts from the works in the library. Books neither rare nor valuable may be lent, by vote of Convocation, to persons working in other institutions of the university, and, by the authority of the librarian or curators, to professors of the university. See Macray, *Annals of the Bodleian Library* (1868; 2d ed. 1890).

Bodley, SIR THOMAS, the restorer of the library originally established at Oxford by Humphrey, Duke of Gloucester, was born at Exeter, March 2, 1545. His family, being forced to flee from England during the persecutions of Mary, settled at Geneva, where Bodley studied languages and divinity under the most distinguished professors of that city. On the accession of Elizabeth he returned to England and completed his studies at Oxford, where he took the degree of M.A., was afterwards elected a proctor, and officiated as public orator. He applied himself to the study of Hebrew, and four years spent abroad enabled him to become proficient in modern languages. He was now employed by the queen in diplomatic missions to Denmark, France, and Holland, and returned to his favourite city, Oxford, in 1597, where he devoted himself to literature, especially to the extension of the university library, now called the Bodleian (q.v.) in Bodley's honour. In collecting rare and valuable books from many parts of Europe, Bodley expended a very large sum, and also left an estate for salaries to officers, repair of the library, and purchase of books. He was knighted by King James, and died at Oxford, January 28, 1613. Having no family, he made the university his chief heir. Bodley's autobiography, extending to the year 1609, together with a collection of his letters, has been published under the title *Reliquiæ Bodleianæ* (1703).

Bodmer, JOHANN JAKOB, a Swiss poet and *littérateur*, was born at Greifensee, near Zurich, in 1698. The study of the Greek and Latin writers, together with the English, French, and Italian masters, having convinced him of the poverty and tastelessness of existing German literature, he resolved to attempt a reformation. Accordingly, in 1721, along with a few other young scholars, he commenced a weekly review, *Diskurse der Maler*, in which the living poets were sharply handled. After 1740, when Bodmer published a treatise on the Wonderful in Poetry, a famous literary war broke out between him and Gottsched, the pedantic dictator of German literature. Bodmer's followers, the Swiss school, who were nourished on English poetry, maintained the claims of imagination and free poetic impulse against poetry according to hard and fast rules. The controversy partly prepared

the way for the Augustan epoch of German literature. Bodmer died at Zurich, where he had held the chair of History for fifty years, 2d January 1783. As an author, he was marked by inexhaustible activity; but his poems, dramas, and translations have no vigour or originality. He did greater service to literature by republishing the old German poets, the Minnesingers, and a part of the *Nibelungenlied*, as also by his numerous critical writings.

Bodmin, the county town of Cornwall, in the middle of the county, 30 miles NNW. of Plymouth. It has some trade in cattle and sheep, and shoes are manufactured. The chief buildings are a market-house, the county hall, and the Cornwall Lunatic Asylum. Bodmin arose out of a priory, which, founded in 936 or earlier, came at the Reformation into Sternhold's hands. The church, rebuilt in 1472, has been restored since 1879. From the time of Edward I. till 1868, Bodmin returned two members to parliament; then, till 1885, one. Pop. 5500.

Bodock. See BOIS D'ARC.

Bodoni, GIAMBATTISTA, a distinguished Italian printer, born in Piedmont in 1740, settled at Parma in 1768, and died at Padua in 1813. His edition of the *Iliad* and of Virgil, as also his Lord's Prayer in 155 languages, are admired for their elegance. See the Life by Bernardi (1873).

Böttcher, LUDVIG, one of the most finished poets the North has produced, was born at Copenhagen in 1793, and after a long residence in Italy, returned home in 1835, to die there in 1874. His poems are mainly love songs, and form but two small collections; but almost every one of them is a gem. See Gosse's *Northern Studies* (1879).

Boduognatus, chief of the Nervii, fell in battle against the Romans on the Sambre, 57 B.C.

Body, HUMAN, will be treated of under the names of the several organs and functions, a list of which is given at ANATOMY.

Body-cavity, in the wide sense, is the space enclosed by the body-walls of an animal, and enclosing the gut and other organs. But this space is not by any means homologous in all animals, and the more precise term *cœlom* was invented by Haeckel to designate the cavity known in Vertebrates as 'pleuroperitoneal.' It is the cavity from the walls of which the germ-cells (ova and spermatozoa) develop, or which forms around these cells. It arises in development from pouches growing out from the primitive gut or archenteron, or by the splitting of solid mesoderm rudiments. It is lined by mesoderm; it is separate from the blood channels; it often contains a perivisceral fluid. A true *cœlom* is very clearly seen in Vertebrates and adult Echinoderms, where it is the cavity into which one cuts in opening an animal. But in many animals the cavity of the body is not a true *cœlom*, and the whole subject is very difficult. The best account of the *cœlom* is to be found in Lankester's *Treatise on Zoology* (1900), Part ii. chap. ii.

Body Colour, a term applied to such pigments as have body enough to be opaque, as distinguished from those which are transparent. As a general rule, pigments have more body the nearer they approach to white; consequently the light parts of pictures in oil are in body colour to give them brightness and strength, while the dark parts are transparent to give them depth. Water-colour painting, when executed by mixing the pigments with white after the manner of an oil-painting, is said to be painted in body colour.

Body's Island, a long, narrow strip of sand, off North Carolina, with a lighthouse (160 feet), the highest in the United States.

Boece (or, more properly, **BOYIS**), **HECTOR**, a distinguished Scottish historian, was born of an old family about 1463 at Dundee. He completed his education at Montagu College, in the university of Paris, where from about 1492 to 1498 he was a regent or professor of Philosophy. Among other learned men whose friendship he acquired here was Erasmus. About the beginning of the 16th century he was invited by Bishop Elphinstone to preside over the university newly founded by him at Aberdeen. Boece accepted the office after some natural hesitation, the yearly salary being but 40 merks, or about £2, 4s. 6d. sterling. The value of money, however, it has to be remembered, was immensely greater then than now, and the learned principal was at the same time made a canon of the cathedral, and chaplain of St Ninians. During his tenure of office the university was highly prosperous and produced many excellent scholars. In 1522 he published his lives, in Latin, of the Bishops of Mortlach and Aberdeen. This work, a great part of which is occupied with the life of his excellent patron, Bishop Elphinstone, was reprinted by the Bannatyne Club in 1825. In 1527 Boece published the Latin *History of Scotland*, on which his fame chiefly rests, a work which, though proved to contain a large amount of fiction, was deemed distinctly critical at the time of its publication. The author was rewarded by the king with a pension of £50 Scots, until he should be promoted to a benefice of 100 merks, which appears to have occurred in 1534. By the excellence of his Latin style, and his sympathy with Erasmus, Boece may fairly be counted a humanist. He died in 1536, and was buried in the chapel of King's College. See BELLENDEN, JOHN.

Boeckh, **PHILIPP AUGUST**, classical antiquary, was born at Karlsruhe, November 24, 1785, and entered the university of Halle in 1803. The prelections of Wolf determined him to the science of philology, of which, in 1809, he became professor at the university of Heidelberg. In 1811 he was translated to the chair of Rhetoric and Ancient Literature at Berlin, where he lectured for upwards of forty years, and where he died, August 3, 1867. Boeckh's conception of philology as an organically constructed whole aimed at nothing short of an intellectual reproduction of antiquity, and consequently excited for a long time great opposition among his professional contemporaries, but it undoubtedly gave an impetus to a deeper study of the old classical world. His lectures include not merely a grammatico-historical interpretation of the ancient authors, but also archaeology proper, the history of ancient literature, philosophy, politics, religion, and social life. His four great works, which have in fact opened up new paths in the study of antiquity, are (1) his edition of Pindar (2 vols. 1811-21), in which the metre and rhythm of the poet, as well as his artistic skill, are investigated and discussed with profound knowledge of the subject; (2) *Die Staatshaushaltung der Athener* (2 vols. 1817; 3d ed. by Frankel, 1887), a work which remains unsurpassed for subtle research, surprising results, and clear exposition: it was translated into English by Sir George Cornewall Lewis under the title of *The Public Economy of Athens* (1828); (3) *Metrolologische Untersuchungen über Gewichte, Münzfusse, und Masse des Altertums* (1838); (4) *Urkunden über das Seewesen des Attischen Staats* (1840). His lesser works are all valuable, and besides investigations in ancient chronology, editions of the *Antigone* of Sophocles (1843), and of the fragments ascribed to Philolaus (1819), and dissertations on Plato's cosmical system, include lectures and critiques collected under the title *Gesammelte kleine Schriften* (7 vols. 1858-74). Boeckh has also the honour of having commenced in

1534 the great work entitled *Corpus Inscriptionum Græcarum*, published at the expense of the Royal Academy of Berlin, and continued by Curtius. See a work on him by Max Hoffman (2 vols. 1901).

Boehm, **SIR JOSEPH EDGAR**, sculptor, was born in Vienna, July 6, 1834. He was educated from 1848-51 in England, and finally settled there in 1862. He had previously gained the first imperial prize in Vienna in 1856, and his work soon attracted notice in the country of his adoption. In 1867 he executed a colossal statue of the Queen, and afterwards received commissions for statues or busts of a large number of distinguished personages. Of the seated statue of Thomas Carlyle, enthusiastically praised by Mr Ruskin in his *Royal Academy Notes*, 1875, a replica was erected at Chelsea. His animal studies are also noteworthy. Boehm was elected a member of the Academy of Florence in 1875, an A.R.A. in 1878, and a member of the Academy of Rome in 1880. He was nominated in 1881 sculptor-in-ordinary to the Queen, and was made an R.A. in 1882, a baronet in 1889. The Queen's effigy on the coinage issued in 1887 was from his designs. He died 12th December 1890.

Boehme, **JAKOB**, a German theosophist and mystic, was born of poor parents at Altseidenberg, near Górlitz, in Upper Lusatia, 1575, and spent his boyhood in tending cattle. He received no instruction till he was ten years of age; but even then, the contemplation of earth and sky had so excited his naturally pious imagination, that he conceived himself inspired. He learned the trade of a shoemaker, and industriously followed that calling for most of his life, but continued to devote much of his time to meditation on divine things. About 1612 was published his first book, called *Aurora*. It contains revelations and meditations upon God, Man, and Nature; betokens a remarkable knowledge of Scripture, especially of the apocalyptic books; as also a familiarity with the writings of the mystico-philosophic alchemists, from whom he largely obtained his phraseology. It was condemned by the ecclesiastical authorities of Górlitz; but the persecutions to which its author was subjected had not the effect of convincing him of his errors. The chief aim of Boehme is to explain the origin of things, especially the existence of evil, and this he does by a mystical process of thought expressed in material symbols, which it is not easy to summarise.

God is the *Ungrund* or *Urgrund*, the original and undistinguished unity, at once everything and nothing, which, however, has in itself the principle of separation, whereby all things come into existence. It is through the principle of negation, which in a way is identified with evil, that creation is explained. His philosophy, in fact, is an application of the principle of contradiction to explain the great problems of philosophy and religion; but the difficulties are only concealed or shifted about under a cloud of mystical language, in which a system of triads, suggested by the Christian doctrine of the trinity, have an important place. In Boehme we have an obscure presentation of the thesis, antithesis, and synthesis, which have such a large application in the philosophy of Hegel. Numerous attacks from theologians disturbed Boehme's last years, but he bore them all with great meekness. So great was the interest excited, that he was induced by the solicitations of certain courtiers and of his friends to visit Dresden for the purpose of having his doctrines investigated. The court applauded and protected him. On returning to Górlitz, he fell ill, and died in 1624. The first collection of his writings was published by Betke (Amsterdam, 1675); the most complete in 1730, at the same place; and the latest (1831-46) by Schiebeler, at

Leipzig. Next to Germany, Holland and England are the countries in which Boehme's works have been received with most favour. In England, where Boehme was generally called Behmen, all his works were translated between 1644 and 1662 (new ed. 1909 *et seq.*). Sir Isaac Newton studied him; William Law of Oxford might be called a disciple; in 1697 Jane Leade, a fanatical disciple of Boehme, founded a sect, called the Philadelphians (q.v.), for the exposition of his writings; and John Pordage, a physician, is also famed among his English interpreters. Abraham von Frankenberg, who died in 1652, published the earliest biography of Boehme. In modern times, and in connection with speculative philosophy in Germany, his views, which had come to be regarded as empty mysticism, have acquired fresh interest and importance. This arises from the kindred character of his fundamental principle with the spirit pervading the systems of Spinoza, Fichte, Schelling, and Hegel. See the works on Boehme and his philosophy by Hamberger (1844), Fechner (1857), Peip (1860), Harless (1870), Martensen (Eng. trans. from Danish, 1885), and Deussen (1911).

Boehmeria, a genus of Urticaceæ (q.v.), of which two species, or rather what were formerly considered as two distinct species, have been from a remote period cultivated in the East. The Indian variety was called by Roxburgh *Urtica tenacissima*, and the Chinese one *Boehmeria nivea* by Gaudichaud.

They are now distinguished as varieties, the one being called *B. nivea* and the other *B. nivea*, var. *condicans*. There is said to be other doubtful species. The fibre from *Boehmeria* has long been used in eastern countries for ropes and for cordage, and also for cloth in China and in Japan. This fibre is known in commerce as Rhea, as Ramie, or as China-grass, and has been much used for sails, tablecloths, and especially the

Boehmeria nivea :

a, male flower; b, glomerule of female flowers; c, single female flower; d, pericarp.

manufacture of incandescent gas mantles. For this purpose, however, it is giving way before artificial silk (see SILK, ARTIFICIAL), from which more uniform, and therefore more robust and durable, mantles can be made. If all the several locally distinguishing forms of the plant be reckoned, it has a very wide range, being found in several parts of India, China, Japan, and the Eastern Archipelago generally. It has been successfully introduced into a number of foreign countries, including the Cape, Mauritius, Algeria, the south of France, California, Louisiana, and some of the West Indian Islands. It may be propagated by cuttings, which can be readily grown, by roots, or by suckers, and it thrives best in moist shady places in the tropics.

Rhea fibre of commerce, which is composed of the bast-fibres on the inner side of the bark of the plant, is difficult to separate in a state suitable for

the manufacturer except by a somewhat costly process. The preparation of the fibre by hand-stripping involves much labour. Machine methods had been experimented with for many years ere a process was found by which it could be prepared so as to be sold at a remunerative price; but now the manufacture promises to become an important industry. The plant abounds in gum, the removal of which without injury to the fibre is another difficulty.

In some respects rhea is the most remarkable of all known vegetable fibres. For fineness, strength, and lustre combined it excels any of them. It can be spun at least as fine as flax, is stronger, and has a more silky lustre. Jute has also this lustre, but it has neither the strength of rhea nor its capability for bleaching and dyeing. Rhea has the additional advantage of being liker wool in its nature than other plant-fibres, and it can be used as a substitute for long-stapled wool.

Boeotia, one of the ancient political divisions of Greece, extended between Attica and Megara on the south, and Locris and Phocis on the north, with an area estimated at 1120 sq. m., or a little larger than Cheshire. The mountain-closed country falls naturally into five divisions—the basin of the Lake Copais, now called *Topolias*, that of the Asopos, the plain of Thebes, and the coast-districts on the Euboean and the Corinthian Gulf. The principal stream was anciently called the Cephissus; which in the spring, when swollen by the rains, almost converted the Copaic plain into a lake. There were several subterranean channels for the outlet of the waters towards the Euboean Sea, but they were not sufficient to carry them off; and in the days of Alexander the Great a vast tunnel was cut in the rock for the discharge of the water. After this fell into ruin, the district became marshy and unwholesome; and it was not till 1895-1900 that it was once more properly drained. The draining operations, carried to a successful completion, drained 60,000 acres of arable land, which now bear wheat, Indian corn, cotton, and other crops. Boeotia has always been fertile. Chomiferous iron ore is obtained.

Of the earliest inhabitants, the most powerful were the Minvæ, who were dislodged by the Boeotians, an Æolian people from Thessaly. The Boeotians excelled as cultivators of the soil, and were brave soldiers both on foot and horseback; but they were rude and unsociable, and took little part in the gradual refinement of manners and intellectual development of the rest of Greece, so that the name became proverbial for illiterate dullness. This was usually ascribed to their thick damp atmosphere. Yet their generals include Epaminondas; and among their poets and historians were Hesiod, Pindar, and Plutarch. The fourteen greater cities formed the Boeotian League, with Thebes at its head. Of this league, a shadow still remained down to the times of the Roman empire. See PLATÆA, and THEBES.—Along with Attica, Boeotia now forms a department or nome of Greece, with an area of 2300 sq. miles, and a population of 582,000.

Boerhaave, HERMANN, the most celebrated physician of the 18th century, was born at Voorhout, near Leyden, December 31, 1668. In 1682 he went to Leyden, where he studied theology and oriental languages, and took his degree in philosophy in 1689. In 1690 he began the study of medicine, and took his doctor's degree in 1693. In 1701 he was appointed lecturer on the Theory of Medicine at Leyden, and in his inaugural lecture recommended to the students the ancient method of Hippocrates in medicine; but in 1703 his views had become greatly enlarged. In 1709 he was

elected professor of Medicine and Botany. About this time he published the two works on which his great fame chiefly rests, *Institutiones Medicæ* (1708), and *Aphorisma de Cognoscendis et Curandis Morbis* (1709), both of which were translated into various European languages, and even into Arabic. In the first work—a model of comprehensive and methodical learning—he gives a complete outline of the theory of medicine; in the second, a classification of diseases with their causes and modes of treatment. Boerhaave also rendered important services to botany. His best lectures include those delivered on his resignation of the office of rector of the university, *De Comparando Certo in Physicis* (1714), and *De Honore Medici, Servitutis* (1736); in the latter of which he declares that to be the servant of nature is the highest aim of medicine. To combine practice with theory, he caused a hospital to be opened, where he gave clinical instructions to his pupils. Though so industrious in his own profession, he undertook in 1718 the professorship of Chemistry, and published in 1724 his *Elementa Chæmiæ*, a work which did much to render this science clear and intelligible, and one that will always occupy a high place in the history of chemistry. His fame had meanwhile rapidly increased. Patients from all parts of Europe came to consult him. Peter the Great of Russia visited him; and it is even said that a Chinese mandarin sent him a letter, addressed 'BOERHAAVE, celebrated physician, Europe.' His character was amiable and unassuming, and tinged with a deep but cheerful piety. He died September 23, 1738, having realised from his profession a fortune of two millions of florins. See BURTON, *Account of the Life and Writings of Boerhaave* (2 vols. Lond. 1743); JOHNSON, *Life of Boerhaave* (Lond. 1834).

Boerhaavia. See NYCTAGINACEÆ.

Boers (Dutch, 'agriculturists,' 'farmers'), the name applied to the Dutch colonists of South Africa who are engaged in agriculture and the care of cattle. The first settlement of the Boers at the Cape of Good Hope dates from the 16th century, and they have since been reinforced by Huguenots from France, but they retain in a pronounced form the old Dutch character, especially the old Dutch love of freedom. After the final cession of the Cape to England in 1814 they disliked the new government, especially its friendly policy to the natives and the emancipation of the slaves in 1833. Accordingly, in 1835, bands of them 'trekked' northwards, and so occupied Natal, the Orange Free State, and the Transvaal. Latterly in England 'Boers' came to mean the Dutch of South Africa, especially of the two republics. In the Boer war of 1899–1902 they amply proved their strong physique and skill as marksmen, and bravery as fighting-men. After the war they took a conspicuous part in the constitution and government of the Union of South Africa. The Cape Dutch, or Taal, spoken by the Boers is a corrupt dialect, with a very limited vocabulary; a compromise between it and the Dutch of Holland (now called, erroneously, 'High Dutch') is preferred in law courts and higher schools. See CAPE OF GOOD HOPE, NATAL, ORANGE FREE STATE, SOUTH AFRICA, TRANSVAAL.

Boëthius (sometimes BOETIUS), ANICIUS MANLIUS SEVERINUS, a Roman statesman and philosopher, was born between 470 and 475 A.D. of a rich and illustrious family. His father had held the office of consul, but died while Boëthius was still a boy. Brought up under the care of men of rank, he studied with enthusiasm philosophy, mathematics, and poetry, translating and elucidating with laborious care the writings of Aristotle, Euclid, Archimedes, Nicomachus, and others. His talents soon attracted notice, and

having gained the esteem and confidence of Theodoric, king of the Goths, who had fixed the seat of his government at Rome in the year 500, he was appointed by that monarch *magister officiorum* in his court. His influence was invariably exercised for the good of Italy, and his countrymen owed it to him that the Gothic rule was so little oppressive. Boëthius was made consul in 510, and his good-fortune culminated in the prosperity of his two sons, who shared the same honour in 522. But his bold uprightness of conduct, springing apparently from his strong faith in the truth of his philosophic ethics, at last brought down upon his head the unscrupulous vengeance of those whom he had checked in their oppressions, and provoked by his virtues. He was accused of treasonable designs against Theodoric; and the king, having become despondent and mistrustful in his old age, was induced to listen to the charges. Boëthius was stripped of his dignities, his property was confiscated, and he himself, after having been imprisoned for some time at Pavia, was executed in 525; according to long subsequent accounts, with circumstances of horrible cruelty. During his imprisonment he wrote his famous *De Consolatione Philosophiæ*, in which the author holds a conversation with Philosophy, who shows him the mutability of all earthly fortune, and the insecurity of everything save virtue. The work is composed in a style which happily imitates the best models of the Augustan age, and the frequent fragments of poetry which are interspersed throughout the dialogue are distinguished by their truthfulness of feeling and metrical accuracy. The *Consolatio* is piously *theistic* in its language, but affords no indication that its writer was a Christian; and if the doctrinal treatises ascribed to him are, as the acutest criticism maintains, not genuine, we must class him in religion rather with Marcus Aurelius than with his alleged friend, St Benedict. Boëthius was the last Roman writer of any mark who understood the Greek language and literature. During the middle ages his translations formed to a large extent the medium by which men became acquainted with Aristotle; and his manuals on arithmetic, astronomy, geometry, and music were generally used in the schools.

Four editions of the works appeared between 1491 and 1847 (Migne). Of the *Consolatio* (often edited) many translations into various languages were made before the invention of printing, such as King Alfred's into English (ed. Sedgefield, 1899) and Chaucer's in English prose (published by Caxton, 1480). Later translations are Queen Elizabeth's (E.E.T.S. 1899), Colville's (1556; ed. Belfort Bax, 1897), I.T.'s (1609; ed. Stewart, 1918), H. N. James's (1897). F. F. Stewart in *Boethius: an Essay* (1891), holds that the philosopher was at least outwardly a Christian, and inclines to believe that the theological tractates ascribed to him were actually his. See KER, *Dark Ages* (1904).

Boethius, HECTOR. See BOECE.

Bog is spongy land covered with Peat (q.v.). Bogs of great extent exist in some of the northern parts of the world. A very considerable part of the surface of Ireland is occupied with them. The Bog of Allen (see ALLEN, BOG OF) is the most extensive in the British Islands. The Solway Moss (q.v.), on the western border of England and Scotland, is about 7 miles in circumference. Chatmoss (q.v.) in Lancashire is 10 sq. m. in extent. There are large bogs in some of the Hebrides and the Orkneys. The swamps of the east of England are in general not peat-bogs, but consist chiefly of soft mud or silt.

The general surface of a bog is always nearly level, but it is usually varied with rushy tussocks rising above the rest, and having a rather firmer soil. By the continued growth of peat, the surface of a bog is gradually elevated; that of Chatmoss,

for example, rises above the level of the surrounding country, having a gradual slope of 30 or 40 feet from the centre to the solid land on all sides. Occasionally, the quantity of water becoming excessive owing to continuous rains, a bog *bursts*, and pours a terrible deluge down the course of a stream causing great devastation, not only by the force of its torrent, but by the enormous quantities of peat which it deposits upon meadows and cultivated fields, as has happened in some memorable instances in Ireland. In December 1896 a large bog of 200 acres burst at Rathmore, near Killarney; several lives were lost, and many miles of country laid waste. The depth of a bog is sometimes more than 40 feet. The spongy mass of which it is formed shakes on the least pressure. Sometimes it is impossible to traverse it; in other cases, it is possible only for those who are well accustomed to it, a false step being a plunge into a quagmire, in which a man sinks as in a quicksand. Safety is sometimes ensured by patters for men and horses. Tradition reports that at the battle of Solway in 1542 a fugitive troop of horse plunged into the moss, which instantly closed upon them.

One of the remarkable phenomena of peat-bogs is the frequent presence of roots and fallen trunks of trees, in a good state of preservation, many feet below the surface (see BOG-OAK ORNAMENTS), and this frequently where no trees exist on the surface now. Two layers of buried trees, marking former land surfaces, appear commonly in the British bogs. Between these, in Scotland, a layer of Arctic plants is often intercalated, and a similar layer now and again occurs at the base of the deeper bogs. Bogs are popularly divided into two classes—*Red Bogs* and *Black Bogs*, the decomposition of the vegetable matter in the former being less perfect, and the substance consequently more fibrous and light, than in the latter. There is indeed no precise line of distinction, and all intermediate conditions occur. The most extensive and deepest bogs are the red bogs; black bogs are more numerous. See BOG-PLANTS.

There can be no doubt that much of the land now occupied by bog is capable of being rendered very productive, whilst the effects of extensive bogs upon the climate are always injurious. The reclaiming of shallow mountain bogs is comparatively easy, and in some cases it is effected by a very simple and inexpensive drainage, and by throwing them at once under cultivation in a manner analogous to that known in Ireland as the *lazy-bed* method of planting potatoes—the soil upon which the bog rests being partially dugged up and thrown over its surface. Great difficulties, however, attend the reclaiming of red bogs; the chief being in some cases caused by the low situation of the bog, and the want of *fall* for drainage. Another serious obstacle is presented by the spongy substance of red bogs being extremely retentive of water, so that a deep ditch only drains a very narrow strip on either side of it. Drainage is certainly effective only when the drains are cut through the peat into the underlying soil, and this operation is often too costly. Where a good soil is known to exist below, the peat is sometimes removed bodily; thus it has been floated off, as in the long-continued operations at Blair-Drummond, on the banks of the Forth. A portion of the peat taken from the upper surface is not infrequently burned in heaps upon the spot, the ashes becoming a manure, and assisting in the formation of a soil.

Of course, the first essential in the reclaiming of bogs is drainage. The method of effecting this must be varied according to circumstances; but very frequently, after a general outlet with sufficient fall has been secured, wide open drains are cut, by which the bog is divided into strips,

which again are traversed and subdivided by smaller drains. When these drains begin to serve their purpose, the surface of the bog sinks, and their depth is reduced; they are then often deepened, and at last a permanent system of covered drains emptying themselves into open ditches is thus formed, and its the land for all the purposes of agriculture. It is, however, often ploughed before this state of things is attained. A heavy dressing of lime, preferably quicklime, may usually be very advantageously applied in order to promote the conversion of the peat into useful soil. Sometimes the first crop taken from the ploughed bog is a crop of oats; sometimes it is found preferable to begin with rape, turnip, or the like. In some places in the north of Ireland fiorin grass (see BENT-GRASS) has been sown on bogs in process of being reclaimed, and enormous crops have been obtained. See WASTE LANDS.

Bogardus, JAMES, American inventor, born in Catskill, New York, 14th March 1800, was apprenticed to a watchmaker, and early showed the bent of his mind by improvements in the construction of eight-day clocks, and by the invention of a delicate engraving-machine. The dry gas-meter is his invention, as is also the transfer-machine to produce bank-note plates from separate dies; and in 1839 his plan for manufacturing postage-stamps was accepted by the British government. Later he introduced improvements in the manufacture of india-rubber goods, tools, and machinery; and invented a pyrometer, a deep-sea sounding-machine, and a dynamometer. He died at New York, 13th April 1874.

Bog Asphodel (*Narthecium ossifragum*), a pretty liliaceous herb, with a characteristic raceme of small golden-yellow star-like flowers, common in early autumn on boggy mountain-sides in northern temperate regions.

Bogatzky, KARL HEINRICH VON, a German devotional writer, was born at Jankowe in Lower Silesia, 7th September 1690. Coming under the influence of Francke, the pietist, he studied theology at Halle from 1715 to 1718. He was a long time in the service of various noble houses of Silesia, and afterwards lived some years at the Silesian village of Glantha, engaged in the organisation of an orphanage there. In 1740 he was received into the family of the Duke of Sachsen-Saalfeld, and on the duke's death he removed to Halle in 1746, where he spent the rest of his life in writing books of devotion, and died 15th June 1774. His chief work is *Das goldene Schatzkuelein der Kinder Gottes*, well known in English translations as Bogatzky's *Golden Treasury*. He wrote also many popular hymns. See his autobiography (new ed. 1872).

Bog-bean. See BUCK-BEAN.

Bog Butter (BUTYRITE or BUTYRELLITE of mineralogists), found in some of the bogs of Ireland, was till 1835 supposed to be of vegetable origin, and due to the decomposition of the peat amidst which it is found. It resembles butter in colour and consistency, and becomes liquid at about 124° F., and is now known to be adipocere constituted by the partial decomposition of butter in contact with air. According to Dingley's travels (about 1680), it was customary in Ireland to treat butter with garlic and sink it in the bog to give it a high taste for Lent; and Petty speaks of butter made rancid by keeping in a bog. See *Notes and Queries*, May 1906 (p. 416), and Joyce's *Social Ireland*.

Bogdanovich, IPPOLYT FEDOROVICH, a Russian poet, born in 1743, became president of the imperial archives in 1788, and died near Kursk in 1803. The mock-heroic *Dushenka* (1778), the best

of his poems, is based on the story of Psyche, and is characterised by a refined and graceful style, and vivacious playfulness of language. His works were collected in 6 vols. (1810).

Bogermann, JOHANN, the president of the famous Synod of Dort, was born in 1576, at the Friesian village of Oplewert. After studying at Heidelberg and Geneva, he became pastor at Leenwarden, and soon distinguished himself by the active part he took in the hot religious controversies of his time, especially that against Arminius. In 1618 he was elected president of the Synod of Dort; but his name is now remembered only for his standard translation of the Bible into the Dutch vernacular. He died in 1633, professor of Divinity, at Franeker.

Boghaz-Keui, a village of Asia Minor, 90 miles E. of Angora, near which are extensive ruins and characteristic sculptures, now recognised as Hittite. The place, doubtfully identified with the ancient Pteria, was unquestionably an important seat of Hittite power and culture. Previously the capital of a minor Hittite state, it was the chief centre of the whole empire or confederacy for two centuries (about 1400-1200 B.C.), and the repository of its archives, in the form of clay tablets inscribed with cuneiform characters. See HITTITES, and books by Hamann and Puchstein (1890), Chantre (1898), Winckler, who conducted important excavations here in 1906-7, and Hrozný; and Cowley, *The Hittites* (1920).

Boghead Coal (TORBANITE or BITUMENITE), a seam met with in the Carboniferous system in the lands of Torbanehill, Bathgate, Scotland. It is rich in Paraffin (q.v.). It is not properly a coal, but rather a bituminous clay or shale.

Bog Iron-ore, a mineral of very variable composition, but regarded as consisting essentially of peroxide of iron and water; the peroxide of iron often amounts to about 60 per cent., the water to about 20. Phosphoric acid is usually present in quantities varying from 2 to 11 per cent. Silicic acid, alumina, oxide of manganese, and other substances, which seem accidentally present, make up the rest. Bog iron-ore occurs chiefly in alluvial soils, in bogs, meadows, lakes, &c. It is of a brown, yellowish-brown, or blackish-brown colour. Some of its varieties are earthy and friable, formed of dull dusty particles; some are in masses of an earthy fracture, often vesicular; and some more compact, with conchoidal fracture. It is abundant in some of the northern and western islands of Scotland, and in the northern countries of Europe generally; also in North America. When smelted it yields good iron (see IRON AND STEEL). Bog iron-ore owes its origin to the chemical action of organic acids arising from the decomposition of plants. These acids attack and dissolve the salts of iron which they meet with in the rocks and soils. The solutions thus formed, when they are exposed to the air, become oxidised, and iron is thus precipitated in the form of hydrous ferric oxide, which, along with the various impurities mentioned above, forms bog iron-ore. This mineral occurs frequently in boggy or badly-drained land, forming the hard ferruginous crust known in Scotland as 'moorland-pan.' According to Eilenberg, the bog iron-ore in the marshes about Berlin owes its origin largely to diatoms.

Bogle, GEORGE (1746-81), born near Bothwell, was sent by Warren Hastings, in the service of the East India Company, to Tibet, where he established friendly relations with the Lama. In 1779 he was made collector at Rangpur. See Sir Clements Markham's book on the expedition (1876).

Boglipur. See BHAGALPUR.

Bog Moss. See SPHAGNUM.

Bog Myrtle, GALE, or SWEET GALE (*Myrica Gale*), an aromatic and resinous shrub, with small lanceolate and serrate gland-dotted leaves,

the only genus of the archichlamydeous order Myricaceae. It covers large areas of bog and of wet moorland in northern regions, and was formerly put to many domestic uses. Its twigs were used to make beds, and to keep away moths and other insects, while its shoots and leaves served as a substitute for hops, its leaves were mixed with tobacco, and wax was obtained from its berries. See CANDLEBERRY.

Bog Myrtle :
a, male catkin, b, female catkin.

Bognor, a Sussex watering-place, 9½ miles SE. of Chichester by rail. Founded in 1786 by a London hatter, Sir R. Hotham, it has an iron pier (1865) 1000 feet long, and a good esplanade, restored since the great storm of 1876. Pop. (1861) 2523; (1911) 8142; (1921) 13,300. For the geological strata called Bognor beds, see EOCENE SYSTEM.

Bog-oak Ornaments. In the peat bogs of Great Britain, Ireland, and other northern countries, trunks of oak, yew, fir, and other woods, which have been long buried, are often found of a dark colour and well preserved, owing to the antiseptic properties of the peaty water. Black oak so found is very suitable for turning and carving. In Dublin a considerable trade is carried on in bog-oak jewelry and other ornaments. The articles made are small models of Irish buildings, Paddy and his pig, brooches, necklaces, fans, crosses, and other trinkets. Upon some of these the harp and the shamrock are frequent adornments. Some patters of the kind that used to be carved are now stamped by a heated die placed in a screw-press. A large proportion of the so-called bog-oak ornaments of the present day are made from ebony, or from artificially stained oak. The trade originated in 1821, and it still continues to be a feature of Dublin industry. Were more attention bestowed on artistic design and on the utility of the products the trade might be capable of considerable expansion. In these respects bog-oak still leaves very much to be desired.

Bogodukhof, a town of Ukraine, on the Merla, 43 miles NW. of Kharkoff. It has a cathedral, an important leather industry, and much trade in cattle. Pop. 12,000.

Bogomili (Slav., 'lovers of God'), a religious sect which arose in the 12th century within the Greek Church in Thrace and Bulgaria. Their theology was dualistic, and resembled that of the Paulicians and Cathari. Out of the eternal Divine Essence or Being sprang two principles—Sataael and Logos; the former, at first good, afterwards rebelled, and created in opposition to the original spiritual universe a world of matter and human beings. These human beings, however, received from the Supreme Father a life-spirit; but this was kept in slavery by Sataael until the Logos or

Christ came down from heaven, and assuming a phantom body, broke the power of the evil spirit, who was henceforth called only Satan. The Bogomili practised a severe asceticism, despised images, and rejected the sacraments. They accepted the whole of the New Testament, but of the Old Testament only the Psalms and Prophets, which they interpreted allegorically. In 1118, that vehement hater of heretics, Alexius Comnenus, burned their leader Basilus. Persecution, however, did not put an end to the Bogomili, and to the time of the Mohammedan conquest of Bosnia (16th century), we find that the greatest number of the renegade Christians who embraced the religion of the conquerors belonged to this sect. Bogomil graves and monuments are common in Bosnia. See Asbóth's *Bosnia and Herzegovina* (trans. 1890), and the article MANICHÆUS.

Bogotá, or SANTA FÉ DE BOGOTÁ, in South America, the capital of the Republic of Colombia, is situated in the province of Cundinamarca, on a tableland which, at an elevation of 8694 feet above the sea, separates the basin of the Magdalena from that of the Orinoco. The tableland has an area of about 400 sq. m., and is bounded on all sides by mountains which, though lofty enough to give shelter, are yet below the line of perpetual snow. This extensive plain—a temperate zone on the verge of the equator, with a salubrious climate and an average temperature of 60° F.—is exceedingly fertile, being as rich in pasturo as in grain. The greater number of its people, however, are sunk in poverty. This is largely due to the heavy cost and difficulty of transport, which hamper all industries. Bogotá is the great commercial centre for the inland territory, and is now connected by railway with its port, Honda, the head of navigation on the Magdalena River (a distance of between sixty and seventy miles); as also with La Dorada and Jirardot on the same river. The few manufactures of the place include soap, leather, cloth, and articles made from the precious metals. Bogotá was founded in 1538, and in 1598 became the capital of the Spanish viceroyalty of New Granada; since 1554 it has been the seat of an archbishop, who has four suffragans. In 1800 it contained 21,464 inhabitants; in 1821, 30,000; in 1884, 95,813; and in 1918, 143,994. Prospectively, the surrounding mountains promise one day to give to industry many valuable minerals, such as iron, coal, and salt. The last two, in fact, have already been obtained to some extent. Mines of emeralds, gold, silver, and copper are also said to exist within the same district. The town is regularly and handsomely built, although most of the houses have but one story, and little glass, owing to the prevalence of earthquakes. The streets are at right angles, and paved and lit, but not over clean. Bogotá teems with churches, its cathedral being famous for a statue of the Virgin, which is covered with costly jewels; its convents were suppressed in 1861. It likewise possesses, in addition to the capitol, a palace for the national chambers, and other official buildings, a mint, a university with six faculties, a number of schools, a free library, observatory, two theatres, and museums; and, supporting about forty journals, the city has been proudly named by its inhabitants the 'Athens of South America.'—The river Bogotá, otherwise called the Funcha, is in itself an object of physical interest. It is the single outlet of the waters of the tableland, which, both from geological features and from aboriginal traditions, appears to have once been a land-locked basin, somewhat like the still loftier and larger plateau of Titicaca. Be this as it may, the river has found, if it has not forced, a passage for itself towards the Magdalena. At the cataract of Tequendama the waters plunge

over a precipice 625 feet high, their force having hollowed out a well 130 feet deep in the rock below; and the clouds of spray clothe the adjacent ground in the most luxuriant vegetation. Some miles from the fall stands the natural bridge of Icononzo, formed as if by the fortuitous jamming of rocks from the opposite sides of the cleft; and the plateau also contains a lake, Guatavita, into which the natives are said to have thrown their treasures when conquered by the Spaniards.

Bog-plants. The extensive areas, especially in the colder regions of the northern hemisphere, which are covered by bogs and marshes, have a highly characteristic flora which is distinct from the fully Aquatic Plants (q.v.) on the one hand, and from the ordinary terrestrial flora on the other. The most important and widely distributed of bog-plants are the bog-mosses (*Sphagnum*), of which the steady upward growth has formed the bulk of our peat-mosses; but higher cryptogamic plants also occur, notably the horsetails (*Equisetum*), and occasionally also rarer forms like *Pilularia* and *Marsilea*. Many sedges and rushes, reeds and grasses, are also highly characteristic, most of all perhaps the curious cotton-grass (*Eriophorum*), while heaths constantly struggle for possession of the drier and denser spots. The Bog-myrtle, q.v. (*Myrica Gale*) often overspreads vast areas with its low, scanty brushwood, above which rise only occasional tufts of willow, or at most here and there an alder. The insectivorous plants are perhaps the most characteristic minor denizens, sundews (*Drosera*) and butterworts (*Pinguicula*) being thickly strewn, while the rarer blossoms of the bladderwort (*Utricularia*) rise golden from their stagnant pools. The margins of these are fringed by the beautiful bog-bean (*Menyanthes*) and the smaller and less spreading forget-me-nots (*Myosotis*), or in spring are gay with marsh-marigolds (*Caltha*) and ranunculuses; while the brown blossoms of the marsh-potentilla (*P. Comarum*), the purplish-pink louseworts (*Pedicularis*), and the curious yellow-rattle (*Rhinanthus*) make their appearance later in summer.

The progress of agriculture completely destroys this flora, hardly a single bog-plant, save the versatile *Polygonum amphibium*, being able to survive thorough drainage. Many beautiful bog-plants can, however, be easily cultivated where a supply of standing water renders possible an artificial re-establishment of their natural conditions, or at anyrate, the continual soaking of their garden border, which should, of course, contain a large proportion of peat. For the geological agency of bog-plants, see PEAT. See also ECOLOGY.

Bog Spavin. This singular name has been applied to a lesion of the hock-joint of the horse, consisting in distension of the capsule enclosing the joint. Sometimes arising suddenly from a spain in action, it most commonly affects young horses with defective hocks, and is associated with other indications of weakness in the injured joint, such as thorough-pin. As the immediate result of a violent spain, the hock becomes swollen, hot, and tender, and there is considerable lameness. The acute symptoms subside readily, but a circumscribed swelling remains towards the front, inner, and lower part of the joint. The swelling is firm and tense, but fluctuating, and partly disappears during exercise, to reappear after rest. At every recurring strain, lameness supervenes, but commonly passes off within a short time. If the bog spavin has accidentally occurred in a young horse with good hocks, it may after disappearance of the acute symptoms never again be attended with inconvenience. The treatment of bog spavin consists in the application of a high-heeled shoe,

without a toe-piece, to the foot; the administration of a purge, soft diet, and rest; and the application of fomentations and mild stimulants to the part, succeeded after a few days by blisters, and perhaps, in cases of persistent lameness, both firing and blistering. Bog spavin is often met with in big, raw-boned, growing colts, and when the animals are well fed and cared for, tends to disappear by the time they reach maturity. See SPAVIN.

Bogue, DAVID, one of the founders of the London Missionary Society, was in 1750 born in Coldingham parish, Berwickshire. He studied at Edinburgh, and was licensed to preach by the Church of Scotland, but went to London to teach in 1771. He afterwards became minister of an Independent chapel at Gosport, and here he also took a tutorship in a seminary for Independent students of theology. This became a great school of missionaries, and out of it grew the scheme for foreign missions realised in the London Missionary Society. Bogue also took an active part in the establishment of the British and Foreign Bible Society and the Religious Tract Society. He was on the point of going as a missionary to India in 1796, when the East India Company refused to sanction the scheme. Bogue died at Brighton, October 25, 1825. He published numerous books, including an *Essay on the Divine Authority of the New Testament*. In conjunction with Dr James Bennet, he wrote a *History of Dissenters* (3 vols. 1809), of great value, though somewhat impaired by partisan prejudices.

Boguslav, a town of Ukraine, 70 miles SSE. of Kieff; pop. 13,000.

Bohemia (Ger. *Böhmen*), formerly one of the kingdoms of Europe, now forms the most westerly part of the Czechoslovak republic, touching Saxony and Prussian Silesia, Moravia, Lower and Upper Austria, and Bavaria. It has an area of 20,000 sq. m., or about two-thirds that of Scotland; pop. (1869) 5,140,544; (1880) 5,560,819; (1910) 6,774,309; (1921) 6,664,932. Of its four hundred cities and towns the most important are Prague (Praha), the capital of the kingdom and now of the republic, with 676,000 inhabitants; Pilsen (Plzeň), over 88,000; and Budweis (Budejovice), with 44,000. The country is surrounded on all sides by lofty mountain-ranges, the principal of which are the Riesengebirge (part of the Sudetic chain) on the north-east, dividing Bohemia from Silesia, and attaining, in the peak of the Schneekoppe, a height of 5330 feet; on the north-west, the Erzgebirge, attaining a height of more than 4000 feet; on the south-west, the Böhmerwald, reaching 4783 feet. Offsets from these traverse the interior of the country, which has an undulating surface, sloping generally to the north. The country belongs to the upper basin of the Elbe, which rises in the Riesengebirge range; and it is well watered by the affluents of that river. The chief of these are the Moldau, the Eger, Iser, Aupa, Mettau, and Biela.

The climate of Bohemia is generally healthy, but varies greatly in different districts. In the valleys it is mild and pleasant, but raw and cold in the mountainous regions, where the higher peaks are covered with snow during a great portion of the year.

The mountain-chains which rise on all sides of Bohemia consist largely of primitive rocks, principally gneiss, mica-slate, and granite. Basalt, clinkstone, greenstone, and red sandstone are also common, and with the last, diluvial and alluvial deposits are met with, often to a considerable elevation. The extensive Silurian beds near Prague are rich in fossils. The plains belong chiefly to the Middle or Miocene period of the Tertiary formation, with sand, gravel, and marl.

A remnant of volcanic action, of which traces are common, still continues in the eruptions of carbonic acid gas which have established so many mineral springs of deserved repute, at Carlsbad, Eger (Cheb), Marienbad, Teplitz, and throughout the country.

The mineral wealth is varied and extensive, consisting of silver, tin, copper, lead, iron, cobalt, bismuth, antimony, alum, sulphur, graphite, and porcelain clay, with several precious and ornamental stones. Much coal is produced. The swampy plains yield an enormous amount of peat, and a large quantity of asphaltum is also obtained. On the other hand, no salt at all is found.

The soil is generally fertile. More than one-half of the area consists of arable land; nearly one-eighth is laid out in meadows and gardens; pastures form about a twelfth; and forests cover nearly a third. Wheat, rye, barley, and oats are raised. Flax and hops are plentiful, and a great variety of fruit is exported in large quantities. The culture of the vine is confined to the vicinity of the Moldau and the Elbe. Cattle, sheep, goats, and swine are reared extensively in some districts; bees and geese form important items in the resources of the country.

In manufactures Bohemia holds a very high place among Continental countries. It is a great centre of dyeing and calico-printing. The linen manufacture is extensive. The chief seat of the woollen manufacture is Reichenberg and its neighbourhood. Other important industries are the manufacture of paper, ribbons, lace, chemicals, porcelain-ware, and the Turkish fez. The glass-works are celebrated, and very numerous and extensive. Much beet-sugar is made, and there are hundreds of breweries and brandy distilleries throughout the country, mostly on a small scale, although Bohemian beer is sold throughout Europe. The manufacture of iron is considerable. Its position secures Bohemia a large transit-trade. Steamboats ply on the Elbe and Moldau, and a canal crossing into Upper Austria conveys the timber of the Böhmerwald from the latter into the Danube. There are good roads and an excellent system of railways centring in the capital, Prague.

Population, Religion, &c.—The Czechs, a Slavonic race, form the bulk of the people, and constitute some two-thirds of the total population, the other third being German. They dwell chiefly in the centre and east of the country. The German population reside mainly around the borders and in the cities; their influence on industry, trade, and commerce is great in proportion to their numbers. The distinction between Czech and German is very sharply drawn. There are about 400,000 Jews. The Roman Catholic Church has lost much by secessions since the republic was formed. The Roman Catholics are under the supervision of the Archbishop of Prague and the three bishops of Leitmeritz, Königgrätz, and Budweis. Education is much more widely diffused than in any of the other former provinces of Austria. At the head of the educational establishments are the German and Czech universities of Prague.

Bohemian Brethren, a religious society, instituted in Prague about the middle of the 15th century, originally composed of remnants of the Hussites. In 1453 they settled on the borders of Silesia and Moravia. The Thirty Years' War entirely broke up the societies of the Brethren; but afterwards they united again, though persecuted. Their exodus and settlement in 1722 on the estates of Count Zinzendorf (q.v.) in Saxony occasioned the formation of the Herrnhuters. See MORAVIANS.

Bohemond I., eldest son of Robert Guiscard (q.v.), was born about 1056, and during his youth distinguished himself in his father's war against the

Byzantine emperor, Alexius Comnenus (1081–85). After his father's death he was excluded from the throne of Apulia by his brother Roger, and only gained the principality of Tarentum after a long contest. He joined the crusade of 1096 with a large army—most of which he had won over from his brother's service—and took a prominent part in the capture of Antioch (1098). While the other crusaders advanced to storm Jerusalem, Bohemond remained in Antioch, where he established himself as prince, and routed the besieging forces of the sultan. He was afterwards made prisoner by a Turkish emir, and remained two years in captivity. Tancred, meanwhile, looked after his interests in Antioch. Bohemond returned to Europe to collect troops, and after defeating Alexius in several engagements, was acknowledged by that emperor as Prince of Antioch. He died in Apulia (1111). His son assumed the government of Antioch in 1126, and was killed in battle (1130).

Böhme. See BOEHME.

Böhmisch-Brod, or BRODČESKÝ, a small town, 20 miles E. of Prague by rail, near which the Hussites (q.v.) were defeated in 1434. See PROCOP.

Bohn, HENRY GEORGE, publisher, was born in London, January 4, 1796. His father, a German, was a bookbinder, and latterly a second-hand bookseller, and young Bohn, adopting the latter business, in 1831 started on his own account, amassed many valuable old books, and in 1841 issued his famous 'guinea catalogue,' containing 23,208 articles. Next he tried the 'remainder' trade, and in 1846 he began the issue of the series of works with which his name is identified. It is impossible to estimate too highly the services he has rendered to the community by republishing, at a cheap rate, a vast number of the most valuable works in literature, science, philosophy, theology, &c. The whole eventually numbered over 600 volumes. He also edited the *Bibliotheca Parviana*, Lowndes's *Bibliographer's Manual*, &c., and issued translations of Schiller, Goethe, and Humboldt, besides a *Handbook of Proverbs*, and a *Dictionary of English Poetical Quotations*. After retiring from business in 1864, his chief stock, copyrights, and second-hand books, realised about £100,000. The china and art collections, sold both before and after his death, realised £45,000. He died August 22, 1884.

Böhtlingk, OTTO, Sanskrit scholar, was born in 1815 of German ancestry at St Petersburg; from 1835 to 1842 studied oriental languages, especially Sanskrit, at Berlin and Bonn; and, after twenty-six years in his native city, removed in 1868 to Jena, and thence to Leipzig. Among his invaluable works are the first European edition of the Indian grammarian Panini (1839), a Sanskrit chestomathy (1845; 2d ed. 1877), and a great Sanskrit dictionary (7 vols. 1835–75). He died in 1904.

Bohun, THE FAMILY OF, was founded by the Norman Humphrey de Bohun, and in 1199 the head of the house became Earl of Hereford. The then Earl of Hereford was taken prisoner at Bannockburn, and a kinsman was slain in single combat by Bruce. In 1380 the heiress of the earldoms of Hereford, Essex, and Northampton, married Henry Bolingbroke (Henry IV.).

Boiardo, MATTEO MARIA, Count of Scandiano, one of the greater Italian poets, was born in 1434 at Scandiano, a village situated at the foot of the Lombard Apennines. He studied at the university of Ferrara, and in 1462 married the daughter of the Count of Norellara. He lived principally at the court of Ferrara on terms of intimate friendship with Duke Borso and Duke Ercole, by the latter of whom he was employed on important

diplomatic missions, and appointed in 1481 governor of Modena, and in 1487 governor of Reggio. As an administrator he was distinguished for his clemency, and is said to have held that no crime should be visited with capital punishment. He died at Reggio in 1494. Boiardo has been called the 'Flower of Chivalry.' His fame rests on the *Orlando Innamorato* (1486), a long narrative poem in which the romances of the Carlovingian cycle are recast into *Ottava rima*. Full of rich and graceful fancy, this is the only work in which the spirit of chivalry is found in union with the spirit of the Renaissance. The chief characters, the Paladins of Charlemagne, are led in a maze of adventure from Paris to Spain, Hungary, Africa, and the far East; Orlando, whose love for the eastern princess Angelica is the central subject, being none other than the hero of the old *Chanson de Roland*. Ariosto adopted Boiardo's characters and magic machinery, and brought his narrative to a close in the *Orlando Furioso*, by which the fame of the earlier poem has been unfairly obscured. After going through sixteen editions before 1545, Boiardo's work became almost forgotten, its vigorous but rough and provincial style being uncongenial to the Florentine taste. Boiardo's other works comprise various Latin eclogues, a versification of Lucian's *Timon*, translations of Herodotus, the *Ass* of Lucian, and the *Golden Ass* of Apuleius, and a series of sonnets and *Canzoni* (Reggio, 1499). See Symonds, *Renaissance in Italy*, and Edwards, *The Orlando Furioso and its Predecessors* (1924).

Boieldieu, ADRIEN FRANÇOIS, an eminent French composer, was born at Rouen in 1775. His talent for music was early developed. At the age of eighteen he brought out a one-act opera in his native town, and two years afterwards he repaired to Paris, where he produced many successful compositions. When the Conservatoire de Musique was established, Boieldieu was elected a professor. The *Cadphe de Bagdad* (1799) was his first brilliant success. His unhappy marriage with the celebrated dancer, Clotilde Mafleury, induced him to accept an invitation to St Petersburg, where from 1803 to 1810 he filled the post of imperial *maître de chapelle*, wrote the music to Racine's *Athalie*, and produced several operas. Returning to Paris, he brought out *Jeun de Paris* (1812), *La Dame Blanche* (1825), his masterpiece, and other popular works. His strength lies in bright and graceful melody, light but tasteful instrumentation, and pure harmony. He has been called 'the French Mozart.' He was elected an academicien in 1817, and on his death, 8th October 1834, the nation honoured him with a public funeral. His native city claimed his heart, and in 1875 erected a monument to him. The government further marked its sense of his merit by granting a pension to his son Adrien (1816–83), who himself composed several operas. See Pougin, *Boieldieu, sa Vie, ses Œuvres* (1875).

Boil, a powerful Celtic people who dwelt originally in Transalpine Gaul, part of whom settled in the modern Bohemia, and bequeathed their name to that country.

Boil (Old Eng. *bȝl*, Middle Eng. *bile*; akin to prov. Eng. and Scots *beal*, 'to supplant'; its present spelling having arisen through confusion with the verb *boil*, which is from the French) is a hard painful swelling of the skin. It usually begins as a small hard point of a dusky red colour, which is hot, painful, and throbbing. This point extends, and these symptoms increase in severity till sooner or later, when the boil ceases to enlarge, it is of a conical form, with a broad firm base, and on the apex a whitish blister, which contains a little

matter; this opens, and after a few days more there is discharged the *core*, a little pellet of dead cellular tissue, and the small cavity left heals rapidly, leaving a white depressed scar. Sometimes boils subside without any breach in the skin, or any discharge. These are known as *blind* boils, and are generally less conical in shape, less painful, and slower in their progress than the common form. Boils rarely occur singly: very often the subjects of them suffer from successive crops during a period of some weeks or months. They may affect any part of the skin, except the palms of the hands and soles of the feet.

Boils are probably always caused by some abnormal condition of the blood or the nutrition of the body, though they often occur in people who appear to be in good health. They are most common in spring; are rare in young children, most frequent in older children and young adults. Any sudden change in diet and daily habits is very apt to cause them; thus persons undergoing a course of hydropathic treatment, or training for races, and country girls going into town as domestic servants, are very apt to suffer. They often occur also during recovery from exhausting diseases.

Recurrence of boils in crops is sometimes checked by a suitable vaccine or by painting the surface of the skin with tincture of iodine. The best application to a boil in the early stages is collodion, frequently repeated, which often prevents its further development, or a square inch of carbolic acid or mercury plaster, with a small hole in the centre, may be applied over the boil. Later, when the pain is severe, the application of small hot poultices will give relief and hasten the progress of the case. Incision is sometimes advisable if the patient's suffering is great. The constitutional condition must always be attended to, and any error in diet or habits corrected. Apeient medicines are generally useful, with, in enfeebled conditions, tonics. Sulphide of calcium, in doses of a tenth to a quarter of a grain, and yeast in tablespoonfuls, help to prevent the formation of new boils.

Boileau, NICOLAS, was born at Paris, where his father was a registrar in one of the law-courts, on the 1st November 1636. He was educated at Beauvais, and received both a legal and a theological training. In his twenty-first year, however, he inherited a competence, and decided to follow a life of purely literary activity. In his youth he appears to have been most generally known by the surname Despréaux, which he had taken in accordance with a practice of the time. He published his satirical *Adieu d'un Poète à la Ville de Paris* in 1660, and in 1663 we find him united with Molière, La Fontaine, and Racine, in the famous 'society of four.' In 1666 he published a collection of satires from which the royal privilege was for a time withdrawn, through the influence of Chapelain, one of the writers whom he had gibbeted. Boileau, however, soon gained the favour of the king, who awarded him various pensions, and in 1677 appointed him, along with Racine, to the post of royal historiographer. *L'Art Poétique*, which contains the exposition of his literary creed, and which was imitated by Pope in the *Essay on Criticism*, was published in 1674, along with four cantos of the *Lutrin*, a clever serio-comic description of an ecclesiastical squabble over a reading-desk. Two cantos, concluding the poem, appeared in 1681. Between 1669 and 1677 Boileau published nine epistles, written, like his satires, on the Horatian model. To celebrate the capture of Namur in 1692, he composed an ode which remains a glaring example of servile flattery and bad verse. This deplorable production was admirably burlesqued by Prior. In his last years Boileau retired

to Auteuil, where he died on 13th March 1711. His works include several critical dissertations in prose, a collection of epigrams, a translation of Longinus *On the Sublime*, a *Dialogue des Héros de Roman*, and a series of letters, a number of which are addressed to Racine, extending from 1672 to 1710. He appears to have been of a jealous, arrogant nature, but not without generosity. Though he secretly preferred Corneille to Racine, he did his best to exalt the younger at the expense of the elder dramatist. Nevertheless, when Corneille's pension was stopped, he is said to have made a courageous protest to the king against 'so barbarous a spoliation.' His verse has wit and vigour, but he never rises to the level of the great satirists. His influence as a critic has been profound. The 16th century had flooded French literature with new words and new ideas. The riches which it had imported and developed required to be sifted, refined, and reduced to order. This task, which had been begun by Malherbe, was carried out with drastic energy by Boileau. He set up good sense, sobriety, elegance and dignity of style as the cardinal literary virtues. He discountenanced the conceits of the salon coteries, and the grossness and grotesqueness of the earlier writers. Through his influence more than any other man's, French prose became almost identical with clear, precise, and polished composition. But for more than a hundred years, while his authority was at its height, there was a distinct falling-off in poetry. Verse was robbed of fire and melody and the power of vague suggestion. The drama was divorced from real life, and restricted to certain prescribed situations and conventional characters. Boileau led Frenchmen to despise the nation's early literature. While he refined he impoverished the vocabulary. The language lost its old pith, colour, and flexibility, and became for a time incapable of reflecting vivid passion or complex character. Boileau's immense influence was thus both beneficial and hurtful to French letters. For more than a hundred years he was accepted by his countrymen as the infallible 'lawgiver of Parnassus'; and inspiration revived only with the Romantic school.

Boiler, the name given to a vessel in which steam is generated. The essentials for a boiler are a closed vessel to contain the water and the steam formed by its evaporation, strong enough to resist the maximum pressure of the steam which the boiler is designed to supply, and a furnace or furnaces, external or internal, for the combustion of the fuel, which may be solid, liquid, or gaseous.

When water is boiled in an open vessel at sea-level the temperature of the water and the steam generated from it remain at or near 100° C., and the tension or pressure of the steam is exactly equal to that of the atmosphere surrounding it, namely, under ordinary conditions, 14.7 lb. per square inch. In a closed vessel, on the other hand, the temperature and pressure to which we can raise the steam are limited only by the strength of the containing vessel against bursting.

Boilers may be divided into two classes, the one in which the vessel holds a comparatively large quantity of water, and the other in which the water is chiefly contained in a number of small tubes; the latter are generally called 'water-tube' boilers. In the first class the outer shell of the boiler is entirely or mainly cylindrical, this being the most economical shape to resist the internal pressure of the steam; the furnace is then usually internal, and the furnace plates provide the most efficient

portion of the heating surfaces through which the heat of combustion passes to the water within; such boilers may be fixed in a brickwork setting or be quite independent of any setting.

Lancashire and Cornish Boilers.—These are horizontal boilers similar in construction, but the former has two internal furnaces, the latter only one; they are both cylindrical in shape, with flat ends stayed to the cylindrical shell and to one another. The furnace is cylindrical, generally extending right through the shell from one end to the other. In the Lancashire type the shell may be 25 to 30 feet in length, and from 6 feet 6 inches to 8 feet in diameter; the furnace-flues are usually about 33 to 36 inches in diameter, and are made in short lengths united to one another by various types of stiffening-rings to assist against collapse; these boilers, according to the thickness of the shell and flue-plates, generate steam at pressures from 60 to 200 lb. per square inch. In one special type, the 'Galloway,' the two furnaces only extend for about 10 feet, then they unite into a single large flue provided with cross-tubes, which extends from the union to the back end plate of the boiler. The Cornish boiler is generally used where less steam and a lower steam pressure is required; it is smaller in overall dimensions than the Lancashire type, and has only one furnace, which may, as is the case with the two furnaces of the Lancashire, have conical cross-tubes in the portion behind the furnace-bridge. In both classes the brickwork

Fig. 1.—Lancashire Boiler.

setting provides one external flue beneath the centre of the boiler, and two side external flues. Fig. 1 shows a cross-section through a Lancashire boiler and its brickwork setting.

For small installations, as, for example, in steam cranes, vertical cylindrical boilers are largely used. In its simplest form the external shell is a vertical cylinder closed at the top by a crown-plate; the fire-box is also a vertical cylinder, but slightly tapered from the bottom to the top; it is united to the outer shell at the base by the foundation-irrig; the top of the fire-box is closed by a crown-plate; the internal smoke-stack passes up through the steam-space and through the crown-plate of the shell. To increase the heating-surface, the fire-box is often fitted with cross water-tubes about 9 inches in diameter; in other types of vertical boilers smaller water-tubes are employed, and some have tubes through which the furnace gases pass from the fire-box on their way to the smoke-box. Fig. 2 shows an example of this class of boiler.

Fig. 2.
Vertical Boiler.

Marine or Scotch Boiler.—This is of the cylindrical multitubular type, and may be single or double ended; in the former the furnaces are at one end, and vary in number from one to four according to the diameter of the shell; each furnace may have its own combustion-chamber, or with four furnaces the two middle furnaces may have a common combustion-chamber, and occasionally one chamber

serves each pair of furnaces on either side of the centre line. In the double-ended type there are furnaces at each end, and usually one combustion-chamber serves for a pair of furnaces, one at each end. From the combustion-chamber the hot gases of combustion pass back to the front of the boiler through a great number of small tubes packed close together, 3 to 3½ inches in diameter; some of these tubes act as stay tubes; the space in front of the tube openings in the front of the shell is closed in, forming the smoke-box, which communicates with the funnel. The staying in these boilers is some-

Fig. 3.—Double-ended Marine Boiler.

what elaborate; above the combustion-chamber level the end plates are stayed by longitudinal round bar stays, the combustion-chambers are stayed to one another and to the outer shell by short screwed steel stays, the flat tops of the combustion-chambers have girder stays, and the tube-plates tube stays. These boilers are constructed up to 17 feet in external diameter, and up to a length of about 12 feet in single-ended, and to a length of 20 feet in the case of double-ended boilers. The usual working steam-pressure varies from 150 to 200 lb. per square inch, though in a few cases still higher pressures have been adopted. They may be worked with natural or forced draught; in the latter case the tubes are usually only 2½ inches in diameter. This type of boiler, in the form known as dry-back boilers, has been used for land purposes, in which case the tubes pass from the combustion-chamber to the back of the boiler. Fig. 3 shows a cross-section of a double-ended boiler.

Locomotive Boilers.—In this type the boiler is made up of a cylindrical barrel, which is joined at its back end to an almost rectangular in section portion inside which is the fire-box, which is itself almost rectangular in cross-section; from the fire-box the combustion gases pass through a series of tubes, 1½ to 2½ inches in diameter, extending through the barrel from the fire-box to the smoke-box at the front end, whence the gases pass up the funnel. In these boilers the staying is similar in general arrangement to that of the marine cylindrical boiler, screw stays, longitudinal stays, and girder stays being all employed. These boilers work up to a pressure of 200 lb. per square inch, and have a large ratio of heating surface to grate area, to allow a rapid combustion of the fuel upon the grate.

Water-tube Boilers are now extensively used both for land and marine purposes; they are quicker and more economical than cylindrical boilers in raising steam, give greater facilities for repair, and have other advantages. There are a number of types used for land purposes; the types most employed in this country are the Babcock and Wilcox, and the Stirling. For marine purposes the earliest and best known were the Belleville and the Niclausse; now those more commonly used are the Thornycroft, the Babcock-Wilcox, and the Yarrow. All these types differ much in their general arrangements and details, but the general principle is more or less similar in all. There is a series of tubes of small diameter,

connected either directly or through the medium of headers with the steam and water drum at the top of the boiler, and with another drum at the bottom. These tubes are filled with water and the flames pass round them. As the water is heated, it rises into the upper cylindrical drum, where the steam is separated, the water passing down again to the lower drum by another set of tubes, and thus a quick and constant circulation is continuously kept up. Some types have one upper receiver only, others as many as four; some have straight tubes, others have bent tubes.

A great many boilers are now fitted with special superheating arrangements, by means of which the temperature is raised considerably above the saturation temperature corresponding to the steam pressure. In ordinary boilers of all types the plating and staying are now invariably made of mild steel. Where small tubes are employed, they are generally lap-welded wrought-iron, but in the case of water-tube boilers, seamless steel tubes are employed. In locomotive boilers the fire-box plates are usually copper, though in the United States they are also made of steel. Where copper is used for the fire-box, the fire-box side stays are copper or bronze. The tubes of locomotive boilers are commonly made of brass; occasionally copper tubes are used.

Boiler Fittings.—Every boiler requires, in order to render it complete and workable, a number of *fittings* or *mountings*, of which the following are the principal: a gauge glass to show the level of the water inside the boiler, and gauge cocks for the same purpose (it is essential that the water-level should be kept well above the heating surfaces); a gauge to show the pressure of the steam; a valve for admitting the feed water; a blow-off cock at the bottom of the boiler for emptying it or for blowing out sediment; a stop-valve for regulating the flow of the steam from the boiler to the steam pipe; one or more safety-valves, weighted so that when the pressure of the steam in the boiler reaches a desired amount the safety-valves open and allow steam to blow off into the air; one opening, closed by doors, by which a man can get into the boiler for cleaning or repair purposes, and frequently smaller openings similarly closed to enable tubes to be cleaned, &c.

In order to maintain an adequate flow of air to the furnaces, so that proper combustion may be secured, land boilers are provided with a brick or sheet-steel chimney of considerable height, the products of combustion passing from the flues to this chimney. In locomotive boilers a powerful draught through the furnace is obtained by the use of the exhaust steam from the engine cylinders, which is discharged through a contracted nozzle opening at the base of the funnel. In marine and many land boilers forced draught is employed, which enables a greater rate of combustion to be maintained in the furnace; jets of steam or fans may be used for this purpose.

Losses by radiation are prevented by covering all parts of the boiler exposed to the atmosphere with some form of non-conducting composition; economy and regularity in steam generation is much improved by the use of automatic stoking machinery, now generally fitted to all large land boilers, though so far such stokers have not been employed with marine boilers.

When the feed water is 'hard,' it is desirable to employ some form of water softening to reduce the degree of hardness of the water before it is fed into the boiler; this much reduces the tendency to scaling on the inside surfaces of the plates and tubes. When the condensed steam from the engines is returned to the boiler, some form of feed filters should be fitted for the removal from the feed water of as much as possible of the oily matter which is

liable to be carried away by the exhaust steam from the engine cylinders. All boilers should be opened up, examined, and thoroughly cleaned at regular intervals.

The efficiency of a boiler is determined by tests, the object of which is to ascertain accurately the proportion of the total heat given out by perfect combustion of the fuel which is utilised in the formation of dry saturated steam, what proportion is lost by imperfect combustion and radiation, and what proportion is lost in the heat carried away up the chimney by the products of combustion and the surplus air. An efficiency of 80 per cent. is rarely reached; 75 per cent. may be taken as that of a good boiler, and in small vertical boilers it more often lies between 50 and 60 per cent. A common method of expressing the performance of a boiler is to give the number of pounds of water which it will evaporate into steam from and at 100° C. per pound of coal fired; in small boilers this may be as low as 6 or 7 lb., and in a boiler of high efficiency it may be as high as 12 lb.

The rate of combustion on the grate varies widely with the type of the boiler and the nature of the draught; with natural draught it may be as high as 18 to 25 lb. of coal per square foot of grate per hour; much higher rates can be obtained with water-tube boilers when forced draught is used, and still higher in the case of locomotive boilers.

Wade, *Efficient Boiler Management*; Bryan Donkin, *Heat Efficiency of Steam Boilers*; Robert H. Smith, *Boilers, Economisers, and Superheaters*.

Boiling as a punishment was in use in England and elsewhere for coiners and poisoners. Several persons were boiled (or immersed in boiling water) at Smithfield under an act of 1531, repealed in 1547, for poisoning, usually for poisoning their employers.

Boiling, Boiling-point. When heat is applied to a vessel containing a liquid (say water) at ordinary temperatures, the temperature of the liquid gradually rises. Vapour may be seen rising from its surface; and, after a time, bubbles of vapour form in the interior and move upwards, but disappear before they reach the surface. The disappearance of the bubbles is caused by the condensation of the contained vapour, and is accompanied by the so-called *singing* of the water. This noise is produced by the falling in of the walls of the bubbles when the vapour is condensed, and increases in intensity as the number of the bubbles increases. If heat be still applied, the temperature rises to such an amount that the bubbles no longer condense, but pass freely to the surface of the liquid. The liquid is then said to *boil*. When this occurs the temperature remains constant on the whole until all the water is boiled off. This temperature is called the *boiling-point*. It may be defined as the temperature at which vapour comes off *freely* from the surface of the liquid. Different liquids boil at different temperatures; and, for each liquid, this temperature increases with increase of the external pressure. The following numbers, extracted from Regnault's tables, show how the boiling-point of water is affected by pressure:

Temperature Centigrade.										
0°	10°	20°	30°	40°	50°	60°	70°	80°	90°	100°
Pressure in Atmospheres										
0.006	0.012	0.023	0.042	0.072	0.121	0.196	0.306	0.466	0.691	1.000

Thus, if the pressure be 0.023 atmospheres, water will boil at 20° C. or 68° F. And if water at a temperature much below its ordinary boiling-point be placed under the receiver of an air-pump and the pressure be reduced, it may be made to boil.

It will give off vapour under these conditions until the pressure rises to that corresponding (as in the table above) to the given temperature. When this condition of equilibrium is reached, the vapour is said to be *saturated*. Thus we obtain another definition—the boiling-point of a liquid is the temperature at which its saturated vapour has a pressure equal to that to which its surface is subjected.

Abnormal boiling-points may be obtained artificially. Thus, if water be carefully heated in a very smooth and clean glass vessel, its temperature may be raised considerably above the ordinary point before it boils. But in this case the boiling takes place explosively when it does begin.

Since the atmospheric pressure depends upon the height above the earth's surface, the boiling-point of water varies with the height. This furnishes the principle of the hypsometric thermometer (see *BAROMETER*, and *HEIGHTS, MEASUREMENT OF*). Under the surface of a liquid the pressure increases with the depth. Hence the boiling-point increases with the depth. This explains the phenomena of the Geysers. See *GEYSER*; also *DIGESTER (PAPIN'S)*, and *SPHEROIDAL STATE OF LIQUIDS*.

Boiling, in *Cookery*. One important preliminary rule in boiling rests on the fact explained in the preceding article, that water cannot be heated in an open vessel, or in one with the ordinary fitting lid of a cooking utensil, to a higher point than 212°. When a vessel, then, has once begun to boil, a stronger fire than is just sufficient to keep it boiling will only evaporate, or waste, the water in steam, but will not cook the food any faster. To boil a joint of meat successfully, it is necessary to place it in water already heated to the boiling-point, in order that the albuminous matters of the skin, &c. may be coagulated as speedily as possible. The coagulated albumen forms an impenetrable coating or varnish, as it were, thus preventing the soaking out of the nutritious juices of the meat. After this has been accomplished, the pot should be withdrawn from the fire, so as to allow the water only to simmer. The cooking goes off through the agency of the natural moisture of the flesh. Converted into vapour by the heat, a kind of steaming takes place within the piece of meat; it is, when skilfully done, cooked by its own steam.

The meat should be trimmed, washed, and dried before it is placed in the water. As it simmers, the water should be kept well skimmed, but with due remembrance of the fact that raising the lid of the vessel lowers the temperature of the water; and the preservation of an equal degree of heat throughout the operation is of the greatest importance. For fresh meat, 20 minutes is the allowance for each pound. The weather must also be considered: in frosty weather, or with very thick joints, extra 20 minutes should be given. Mutton loses in boiling, in 1 lb., 3½ oz.; beef, in 1 lb., 4 oz. Meat that has been salted and dried has its outer coat already sealed up; it requires, therefore, to be thoroughly washed, soaked for 2 hours in cold water, dried, and put to boil in cold water, gradually brought to the boiling-point, and kept simmering for a time proportioned to the size of the piece. Hams and tongues to be eaten cold, should be allowed to cool in the water in which they have been boiled. The following is a time-table for the cooking of these meats, reckoning from the time the water boils: A ham of 16 lb. takes 5 hours; a tongue of 16 lb., 2 to 4 hours; a pig's face of 16 lb., 2 hours; a piece of bacon of 4 lb., 2 hours.

Before boiling poultry or fish, it is advisable to rub the outside skin with a cut lemon. This insures a snowy-white appearance in the cooked food. Fish should be placed in cold water, in which a tablespoonful of salt and one of vinegar is mixed;

should be gradually brought to the boiling-point, and simmered carefully, lest the outer part should crack before the thick part is done. If on drawing up the fish-plate, a thin knife will easily divide the flesh from the bone in the thick parts, and if the eyes contract, and become like balls, the fish is sufficiently cooked. Drain by laying the plate across the kettle covered with the lid, and dish perfectly dry on the strainer, which should be covered with a napkin.

Vegetables require generally to be well washed, and placed in boiling water, in which is mixed a large spoonful of salt. To preserve the green colour they are best boiled in a pan without a cover. When they sink they are done. Green vegetables should be well picked, soaked in salt and water, drained and boiled in plenty of water, in a vessel without a lid. Cabbage requires two waters; spinach, very little, as it is full of moisture. Pease and beans should not soak, but be merely rinsed in a colander. Winter potatoes should soak for an hour or more; whether they should be placed in cold or boiling water depends on the description. A piece of soda the size of a small marble assists the boiling of pease and cabbage, if the water is very hard.

Frying is practically boiling in fat or oil, and when properly carried out, with a pan full of oil, is the preferable way of cooking fish and some vegetables.

Bois d'Arc (sometimes corrupted into *BODOCK*), also Bow-wood, or Osage-orange (*Machura aurantiaca*), a tree belonging to the dicotyledonous order *Moraceae*, is a native of the Southern United States. Its large beautiful orange-like fruits are scarcely eatable, but its spines make it useful as a hedge plant. Its wood is strong, and hard, and elastic, and hence was used by the Indians in the manufacture of their bows.

Bois-de-Boulogne. See *BOULOGNE*.

Boise (formerly *Boisé City*), capital of the state of Idaho, U.S., near the Boise River, 520 miles NE. of San Francisco. The public buildings include a United States assay-office, gold being the principal article of export. A branch railway, 20 miles long, connects the city with the Oregon Short Line Railroad. Pop. 20,000.

Boisgobey, FORTUNÉ DU, a French novelist, was born in 1824 at Granville in Normandy, and died 26th February 1891. After several campaigns in Algeria as army-paymaster, he made his first appeal to the public in 1868, with a story in the pages of the *Petit Journal*. It was followed in quick succession by a crowd of sensational stories which soon gained a certain popularity even in England, spite of the exceptionally poor quality of the current translations. A close follower of Gaboriau, he has all his master's vigour and ingenuity, but lacks that sense of dramatic fitness and respect for verisimilitude which saved the original from the impossible absurdities of the imitations. But lovers of 'police-novels' are not exacting in literary workmanship, and Du Boisgobey's stories are at least always readable. Among the best are *L'Homme sans Nom* (1872), *Le Forçat Colonel* (1872), *L'As de Cœur* (1875), *Les Mystères de Nouveau Paris* (1876), *Le Crime de l'Opéra* (1880), and *Le Secret de Berthe* (1884). Some twenty of them have been translated.

Bois-le-Duc (Dutch, 's *Hertogenbosch*, 'Duke's Forest'), a city of the Netherlands, capital of North Brabant, is 28 miles SSE. of Utrecht by rail. It is a clean, well-built town, about 5 miles in circumference, intersected by canals, and was strongly fortified till 1876. Bois-le-Duc is the seat of a Catholic archbishop, and has a very fine cathedral (1312-1498), a town-hall, college, arsenal,

an academy of arts, a grammar-school, &c. Iron-founding, book-pinting, the making of beer, spirits, leather, woollens, cigars, jewellery, linen-thread, ribbons, and cutlery, are the principal industries. Bois-le-Duc was founded in 1184 by Godfrey III., Duke of Brabant, in a wood; hence its name. His son Henry strengthened the town with walls. The town was ineffectually besieged in 1601 and 1603, but surrendered to the Dutch in 1629. In 1794 it was taken by the French, and in 1814 retaken by the Prussians. Pop. 40,000.

Boisserée, SULPIZ, was born at Cologne in 1783. Inspired with the idea of collecting the scattered specimens of early German art, he and his brother Melchior gathered together two hundred pictures in a gallery in Stuttgart. In 1827 the collection was sold to the king of Bavaria, and in 1836 transferred to the Munich *Pinakothek*. Sulpiz, who died in 1854, was author of *Geschichte des Doms von Köln* (1823-32) and other important works. See his Life by his widow (1862).

Boissonade, JEAN FRANÇOIS, Hellenist, born at Paris in 1774, became in 1809 titular, and three years later actual professor of Greek in the university of Paris; in 1813 member of the Academy of Inscriptions; and in 1828 professor of Greek Literature in the College of France. His more important works are *Philostrati Heroica* (1806); *Marina Vita Procli* (1814), *Tiberius Rhetor de Figuris* (1815), *Sylloge Poetarum Græcorum* (1823-26), *Babrii Fabula* (1844). He died at Passy, 8th September 1859.

Boissy d'Anglas, FRANÇOIS ANTOINE, COUNT, French statesman, born at St Jean Chambre, in Ardèche, in 1756, was for some time major-domo to the Count of Provence (Louis XVIII.), and a member of the States-general. During the Reign of Terror, fear of the 'Mountain' kept him quiet; but, yielding to the solicitations of Tallien and Barrère, he joined the conspiracy against Robespierre. Two months after the execution of the tyrant, he was elected secretary of the Convention; and shortly after, a member of the Committee of Public Safety, in which capacity he displayed remarkable talent and discretion. As director of the supply of provisions for Paris, he was exposed more than once to popular hatred, but firmness and presence of mind preserved him. He was afterwards president of the Council of Five Hundred; was called into the Senate by Napoleon; and made a peer by Louis XVIII. Through all the changes of the times he maintained the principles with which he had commenced his career. He died in Paris, October 20, 1826. His chief writings are: *Recherches sur la Vie, les Écrits, et les Opinions de Malesherbes* (1819), and *Études Littéraires et Poétiques d'un Vieillard* (1826).

Boito, ARRIGO (1842-1918), Italian composer and poet, was born at Padua, and studied at the Milan Conservatorium. His first important work, the opera *Mefistofele*, produced without success in 1868, has steadily grown in popularity. It betrays the influence of Wagner. Other operas, *Ero e Leandro*, *Nerone* (1924), *Orestide*, were not produced in his lifetime. He wrote his own and other libretti, and several songs, lyrical dramas, and novels.

Boivin, MARIE, a French midwife, born in 1773, became a nun; but after the destruction of the nunnery at the Revolution, she devoted herself to midwifery. So distinguished was she as superintendent of the Maternité at Paris, that the king of Prussia conferred an order on her, and Marburg University the degree of M.D. She died in 1841.

Bojador, CAPE, a headland on the west coast of Africa, in 26° 7' N. lat., 14° 29' W. long. The Portuguese doubled this cape in 1432.

Bojano, an ancient Italian town with a cathedral, on the Biferno, 13 miles SW. of Campobasso. Pop. 6000.

Bojer, JOHAN, Norwegian novelist, born at Tjondjem in 1873, was influenced by Zola and Knut Hamsun. Of his realistic novels of peasant life, *The Power of a Lie* and *The Great Hunger* have been translated.

Bokhara, an independent state of Central Asia, in alliance with Russia (1921), is bounded to the north by Samarkand, Syr Daria, and Ferghana, east by Ferghana (the Pamir), west by Khiva and Transcaspia, south by Afghanistan. The population is estimated (Islam forbidding a census) at from 1,250,000 to 3,000,000; the area is about 80,000 sq. m.

Central and Eastern Bokhara are mountainous, with great glaciers and peaks exceeding 20,000 feet; Western Bokhara (i.e. W. of 66° E.), forming nearly one-third of the country, consists of steppe and desert, but contains the fertile and highly populated oases of the Zarafshan. The Hissar and Zarafshan ranges (attaining 18,000 feet) separate Bokhara from Samarkand; the Amu-Daria (Oxus) and its tributary the Panj for over 700 miles divide Bokhara from Afghanistan. Bokhara's eastern extremity includes the lofty and sparsely inhabited regions of West Pamir, Vakhan, Shugnan, and Roshan. North of Badakhshan (q.v.) are the mountainous provinces of Daiwaz and Karategin (q.v.), Peter the Great range (nearly 22,000 feet), and the Surkhab or Vaksh, which, flowing into Bokhara between the Alai and Transalai Mountains, runs SW. to unite with the Panj in the Amu-Daria. The middle section, in which lies Hissar (q.v.), has high plateaus and cultivated valleys—the Kafir-nihan and Surkhan, which join the Amu-Daria, and the Kashka-Daria, with the populous towns of Karshi (q.v.), Kitab, Shar (Chaar), &c. In the west is Bokhara proper, fertilised by the lower Zarafshan (which, like the Kashka-Daria, is smothered in sand before reaching the Amu-Daria) and developed by the Transcaspian Railway, laid (1886-88) across the desert from Chaijui (q.v.), on the Amu-Daria, to Bokhara City, and thence up the Zarafshan to Samarkand. The Zarafshan ('Strewer of Gold,' the *Polyimetus* of the ancients) rises in a glacier to the N. of Karategin at an altitude of about 9000 feet, and flows through Samarkand province between the Turkestan and Zarafshan ranges (which continue the Alai Mountains westward). At Samarkand city, midway in its course of 400 miles, it is only 2400 feet above sea-level. Below Katta-Kurgan it enters Bokharan territory, and flows through level country past Kerminé and Bokhara city to Karakul and Dengiz-Kul, salt lakes, 15 to 20 miles from the Amu-Daria. From about 66° E., between Kelif and Keiki, the Amu-Daria flows north-westwards through Bokharan deserts towards Khiva and the Aral Sea. West of the Zarafshan is likewise desert.

The climate is healthy, but subject to great extremes of heat and cold. The cultivated pairs (chiefly Zarafshan, Kashka-Daria, Hissar, and Karategin valleys) depend not on the spring rains, but on irrigation, facilitated by the melting of highland snow and glaciers, and on fertile loess from the disintegrating mountains, carried by winds and deposited by rivers. Sand-storms and drifting sands are frequent, and the problem of desiccation engages men of science and officials. Bokhara's mineral resources have been little studied, and transport difficulties militate against exploitation. The sands of some rivers yield a little gold. Salt deposits are numerous. The products of the soil include cotton and rice, wheat, barley, durra, lucerne, sesame, millet, hemp, tobacco, melons, pumpkins, fruit, and vegetables.

Sheep and goats form a great source of wealth; the skins of Karakul lambs are known as astrakhan. Camels are numerous and valuable, the horses and yak-oxen are celebrated for their endurance, and the breed of asses is excellent. Myriads of silkworms are fed on the mulberry-trees that clothe the banks of every stream. The manufactures include silk-stuffs, cottons, jewellery, cutlery, firearms, carpets, leather-work, brass-ware. Its geographical position secures Bokhara a great transit-trade.

Bokhara, which in ancient times formed part of Sogdiana (q.v.), was conquered in the beginning of the 8th century by the Arabs, who were dispossessed of it by Genghis Khan. It fell into the hands of Timur, and about 1500 was taken by the Uzbeks, its present masters. During the 18th century, thanks to its khans, vice, and fanaticism, Bokhara lost its political pre-eminence among the khanates of Turkestan. The canals, which alone gave fertility to the country, were neglected; large areas were again overspread by the desert; and the population diminished. With the accession of the Khan Nasrullah (1826), a barbarous and incapable tyrant, the country became an object of rivalry to Britain and Russia, who sent envoys to cultivate his friendship (see BURNES); but he and his successor, Mozaffar-ed-din, treated both with equal insolence and contempt. After the capture of Tashkand by the Russians in 1865 (see TURKESTAN), a religious war was preached against the Russians, and the khan was compelled to oppose them. He was defeated at the battle of Irdjar, May 20, 1866; and in May 1868 Samarkand (q.v.), one of the most important cities of Bokhara, was taken. The Russians' command of the upper course of the Zarafshan, which fertilises the capital and country, placed the khan entirely under the power of Russia. In July 1868 Samarkand was ceded to the tsar, and Russians were granted trade privileges (extended in 1873) in Bokhara. The treaty caused great dissatisfaction to the fanatic Mussulmans of Bokhara, who rose in rebellion. The Russians aided the khan at his request; and in October the rebels were defeated near Karshi. The rebel leader, the khan's son and heir, sought refuge in Afghanistan, with which hostilities nearly followed. During the invasion of Khiva (q.v.) in 1873 the khan efficiently assisted the Russians. After the loss of Samarkand the khan's power was extended and consolidated to the east and south. Mozaffar-ed-din in 1885 was succeeded by Abd-ul-Ahad, his younger son, whose mental and physical weakness rendered him anxious to secure the protection of Russia. A Russian political agent was appointed in 1888, and by degrees, with the help of the Transcaspian Railway, the country was practically absorbed into Russian Turkestan. In 1892 Russia extended its customs to the Bokharan-Afghan boundary. The Russians interfered little with the internal administration, the khan or emir enjoying despotic powers, and, like the begs who governed the semi-independent provinces, taxing his subjects to the utmost. The army numbered about 11,000. Owing to excessive impositions and sectarian animosities, sanguinary rioting broke out in Bokhara after the accession of Abd-ul-Ahad's son, Sayid-Mir-Alim (January 1911), but it was suppressed by Russian troops. A 'Young Bokharan' revolutionary movement and Russian invasion occurred in 1920. The khan fled to Afghanistan, and the Soviet system was set up.

See TURKESTAN; Vambéry, *History of Bokhara* (1873); Carzon, *The Pamirs and the Source of the Oxus* (1897); Olufsen, *The Emir of Bokhara and his Country* (1911).

BOKHARA, the capital, is situated on a plain a few miles from the Zarafshan, in the midst of trees and gardens. It is between 8 and 9 miles in circum-

ference, and surrounded by embattled mud walls about 24 feet high, pierced by eleven gates. The houses, which are small and ill-lighted, are built of sun-burned bricks on a wooden framework; and the roofs of all are flat. The streets are ill-paved, crooked, and very narrow. The principal square is called Rigistan; here the British emissaries, Stoddart and Conolly, were executed in 1842. The old citadel and palace (the 'Ark') occupy a slight eminence in the centre of the city. The mosques are said to be 365 in number, Bokhara being the centre of Islamic life and learning in Central Asia. The most imposing one occupies a square of 300 feet, and has a cupola 100 feet high, ornamented with blue tiles. Attached to it is a tower of about twice the height, from which till 1888 criminals were hurled. The city contains over 100 schools and colleges, attended by some 10,000 students; among these, in past times, have been pupils from India and Chinese Turkestan. A canal intersects the city, but the water, which becomes very scarce in summer, is at all times a source of disease from the filthy state in which it is kept. Although ancient, the city is not as old as Samarkand. Bokhara has long been the most important commercial town in Central Asia. Silks, woollens, carpets, and swords are manufactured, and there is a large trade in Russian goods; the town boasts fifty caravanserais and as many bazaars, gorged with the richest ware of Europe and of Asia. Bokhara is connected by a narrow-gauge line (8 miles) with New Bokhara, a Russian town on the Transcaspian Railway. The population is estimated at from 70,000 to 100,000 (including a number of Jews). See TURKESTAN.

Bokhara Clover. See MELLIOT.

Boksburg, an important coal and gold mining centre in the Transvaal, on the Witwatersrand, 15 miles east of Johannesburg; pop. (1921) 38,115 (including 12,406 Europeans).

Bolan' Pass, (1) a narrow, precipitous gorge, about 54 miles long, ascending in a generally north-west direction from Kolpur (or Kharlakai Kotal) to Rindli, and lying pretty directly between Sind and Kandahar. The ascent is about 5900 feet. Along the bottom of the pass descends a torrent, now repeatedly bridged by a good military road; and in 1885-86 a railway was laid for military purposes. The route, without being impracticable, is highly defensible in a military point of view, and is commanded by the fortress at Quetta, now British. It is bounded throughout by eminences which sometimes attain a height of 800 feet; and yet, in 1839, a British column of artillery accomplished the whole distance in six days. From the northern outlet there is no fall, and a good road runs to Quetta, 25 miles away.—(2) A district of Baluchistan, area 896 sq. m., including the pass, the civil station of Rindli, and jurisdiction over the road and railway to within 13 miles of Quetta.

Bolas (Span., 'balls'), missiles used by the natives and *gauchos* of southern South America, consisting of two heavy balls, generally of stone covered with leather, connected by a plaited thong 6 to 8 feet long. One bola is held in the right hand, while the other is swung rapidly round the head, at the full extent of the thong, and both are discharged at the animal to be captured, so as to wind round its feet, and bring it to the ground. In another form of bolas there are three balls, not of the same size, connected at the common centre by three short thongs or ropes.

Bolbec, a busy town in the French department of Seine-Inférieure, 19 miles ENE. of Havre by rail. A stream of the same name supplies water-power for several mills, where woollens,

linen, cotton, and chemicals are manufactured. Pop. 10,000.

Boldrewood, ROLF, pseudonym of Thomas Alexander Browne (1826-1915), author of *Robbery under Arms* (1888), *The Miner's Right* (1890), and *Old Melbourne Memories* (1895)—perhaps his best book. Born in England, he was taken to Australia in 1830 by his father, Captain Sylvester John Browne, one of the founders of Melbourne; and there, after a good education and a varied experience in stock-farming and other vocations, he became a police magistrate and goldfields commissioner. He retired in 1895.

Bole is an earthy mineral resembling clay in structure, and consisting essentially of silica, alumina, red oxide of iron, and water, which occurs in nests and veins in basalt and other basic igneous rocks. It feels more or less greasy when placed between the fingers; is of different colours—yellow, red, brown, and black; has a dull, resinous lustre, but a shining streak; and is readily friable and not plastic. Armenian bole has a red tint, and is used for colouring tooth-powders and false anchovies. Lemnian Earth (containing a large percentage of silica) is the bole from the island of Lemnos; it is red in colour, and was at one time prescribed as a tonic and astringent medicine—no doubt from the large percentage of oxide of iron present. The boles which are employed in veterinary practice in Europe are generally made from Armenian bole. The savage tribes in South America eat bole to allay the pangs of hunger. When bole is calcined, it becomes hard; and when afterwards levigated, a coarse red kind is used as a pigment. French bole is pale red; Bohemian bole, reddish yellow; Silesian bole, pale yellow; and Blois bole is yellow.

Bole'ro, a Spanish national dance, invented in 1780 by the dancer Sebastian Zerezo. It is danced in moderately quick three-quarter time by two persons to the accompaniment of the castanets and the guitar. The name is also applied to the air to which it is danced. Like the *fandango* it is said to be originally a refinement of an African dance still performed by the Congos under the name of *chika*.

Boletus, a genus of Hymenomycete Fungi (q.v.). The older botanists included in it the numerous species now forming the genus *Polyporus* (see *AMADOU*, *DRY ROT*, and *POLYPORUS*) and other genera; but even as now restricted, it includes about one hundred European species. Most of the species resemble the common mushroom and other species of *Agaricus* in general form, but are distinguishable at a glance by the pore-like surface occupying the place of gills. Unlike *Polyporus*, the whole spore-bearing tissue (hymenium) is easily detached. Some of the species

Boletus edulis.

are edible. *B. edulis* is much used in France, also in Germany, Hungary, Russia, &c. It is the *ceps ordinaire* of the French markets. It grows on the ground in thin woods of oak, chestnut, or beech, and sometimes in mountainous districts, in places covered with moss, heath, or grass. In moist warm summers it sometimes appears in prodigious quantities. It has also been partially cultivated by inclosing a portion of a wood, and watering the ground with water in which the plant has been steeped, thus, in fact, sowing its minute

spores. In Britain it is comparatively rare. The cap is smooth, 6 or 7 inches across, with a thick margin, varying in colour from light brown to brownish black; the tubes at first white, then yellow, and finally yellowish green; the stem thick and solid, beautifully reticulated. The tubes are removed along with the skin and stem, and only the flesh of the cap is eaten, which is firm, white, delicate, of agreeable smell, and is prepared like the common mushroom, dried to flavour sauces, ragouts, &c., or eaten raw with salt and pepper. It is wholesome and nutritious, and is certainly to be reckoned one of the very best of the edible fungi. —*B. scaber* is another edible British species, but much inferior. —*B. aeneus* is the *ceps noir* of the French markets, and *B. aurantiacus* is the *girolle rouge* or *roussille*. They are used like *B. edulis*. Forms of which the flesh turns blue when broken and exposed to the air, should be avoided as probably poisonous.

Boleyn, ANNE, second wife of Henry VIII., was born in 1507, and was the daughter of Sir Thomas Boleyn, afterwards Viscount Rochford and Earl of Wiltshire, by Elizabeth Howard, daughter of the Duke of Norfolk. She spent some three years (1519-21) at the court of France, and soon after her return to England was wooed by Lord Henry Percy, the heir to the earldom of Northumberland, and by King Henry himself, who in the April of 1522 began to shower wealth and honours on her father, and who ere this had dishonoured her sister Mary. Not till the king's divorce from Catharine of Aragon was set afoot (in May 1527) does Anne seem to have favoured his addresses; but long before Cranmer pronounced the divorce (23d May 1533) she was Henry's mistress, and in the preceding January they had been secretly married. She was crowned with great splendour in Westminster Hall on Whitsunday; but within three months Henry bade her 'shut her eyes to his unfaithfulness, as her betters had done, for he could abase yet more than he had raised her.' His cooling passion was not revived by the birth, in September 1533, of a princess, the famous Elizabeth, still less by that of a still-born son, on 29th January 1536, barely three weeks after the death of Queen Catharine. On next May-day the king rode off abruptly from a tournament held at Greenwich, leaving the queen behind, and on the morrow she was arrested and brought to the Tower. The story runs that his jealousy was kindled by her dropping a handkerchief to one of her lovers in the lists below; anyhow, a week before, a special commission had been secretly engaged in examining into charges of Anne's adultery with her own brother, Lord Rochford, with Sir Francis Weston, Henry Norris, and William Brereton, gentlemen of the privy chamber, and with Mark Smeaton, a musician. Only Smeaton made any confession; but on the 12th the four commoners, on the 15th Anne and her brother, were tried and convicted of high treason. Her own father and her uncle, the Duke of Norfolk, were instrumental in her death, the latter presiding over her judges, the twenty-six peers, and pronouncing her doom. No vestige of the evidence remains. On the 17th Smeaton was hanged, and the other four beheaded; and two days later, upon Tower Green, Anne submitted her slim neck to the headsman's axe. Henry the next day married Jane Seymour. That Anne was guilty of adultery with Henry is certain; that she was guilty of incest with her brother, or even of adultery with her other alleged paramours, remains at least not proven. The character of this 'mother of the English Reformation' was not saintly; but she probably was not the Jezebel that Nicholas Saunders would have us believe.

According to him, she was even in person ugly, misshapen, monstrous; whereas we know that she was a comely brunette, her only defect a supplemental nail. See Hepworth Dixon's *History of Two Queens* (1874); Paul Friedmann's *Anne Boleyn* (1885); Martin Hume's *Wives of Henry VIII.* (1905); and works cited under HENRY VIII.

Bolgary, a village in the Russian government of Kazan, near the Volga, with about 150 houses. It occupies the site of Bolgar, capital of the old Bulgarian kingdom, remains of which, in the form of ruined buildings, walls, and minarets, yet attest its former state.

Bolgrad, a town in the Rumanian region of Bessarabia, 28 miles NW. of Ismail, at the head of Lake Yapuch, a feeder of the Danube. It is well built, and has some trade and manufactures of soap, candles, pottery, &c. Pop. 13,000, many of them Bulgarian immigrants.

Boli, an ancient town of Asia Minor, on the left bank of the river Boli, 136 miles E. by S. of Constantinople. Pop. 5000.

Bolide is a name given to a large meteor which explodes and falls in aerolites; a fire-ball. See METEORS.

Bolingbroke, HENRY ST JOHN, VISCOUNT, one of the most gifted of English statesmen and orators, was born at Battersea, on October 1, 1678. He belonged to a good family, and was educated at Eton. The statement which his various biographers have repeated of his having matriculated at Christ College, Oxford, has been disproved by recent research. After travelling on the Continent, he entered parliament in 1701 as member for Wootton Bassett. There were at the time three political parties, the Jacobites, the Tories, and the Whigs. Bolingbroke joined the Tories, and gained immediate distinction by his vigorous and polished eloquence. From 1704 to 1708 he was Secretary for War in the Godolphin ministry; in 1710 he became Foreign Secretary, and shared the leadership of the party with Harley. He was called to the House of Lords in 1712, and in 1713 he negotiated the Peace of Utrecht. This was the one act of his political career which was of benefit to his country. It did not, however, bring him popularity as a statesman, and he estranged his followers by his morbid love of secret scheming, his desire to do everything alone and in the dark. After plotting successfully for Harley's downfall, he set to work to form a Jacobite ministry in July 1714. A week afterwards his designs were shattered by the death of Queen Anne. George I. came to the throne, and Bolingbroke, who had intrigued on behalf of the Stuart cause, fled to France. He was attainted in 1715, and acted for some time as Secretary of State to the Pretender. While living abroad he wrote his *Reflections on Exile*, and addressed a letter to Sir William Wyndham, in vindication of his political career. His first wife, a daughter of Sir Henry Winchcomb, having died in 1718, he married in 1720 the rich widow of the Marquis de Vilette. By the shrewd use which he made of this lady's wealth, he obtained permission to return to England, where he was not allowed, however, to sit in the House of Lords. He then settled at Dawley, near Uxbridge, and became the associate of Pope, Swift, and other men of letters. It was his ambition to be ranked among philosophers, but the ethical studies in which he engaged could not wean his attention from politics. He intrigued in London for an office which he never obtained, and attacked Walpole with the utmost bitterness in a series of letters which appeared in the *Craftsman*, and were reprinted as *A Dissertation on Parties*. Disappointed in his hopes of readmission to political life, he returned to France, where he

remained from 1735 to 1742. During these years he produced *A Letter on the True Use of Retirement*, and his most important contribution to literature—the *Letters on the Study of History*. The precepts which he laid down for the historian's guidance were indorsed by Voltaire and carried into practice by Macaulay. Bolingbroke's last years were spent at Battersea, where he wrote his *Letters on the Spirit of Patriotism*, and his *Idea of a Patriot King*. He died, after a long illness, on the 12th December 1751. 'The Alcibiades of his time,' Bolingbroke is one of the most interesting and brilliant figures in English history. He was idolised by his contemporaries for the grace of his person, the charm of his manner, and the splendour of his talents. An admirable speaker and writer, he was not a great statesman—hardly a skilful party leader. He was the arch-intriguer of his time; as a politician he was thoroughly selfish and insincere. In his writings he preached a double morality; while he considered Christianity a fable, he held that a statesman ought to profess the doctrines of the Church of England. His philosophy is sensational; and as a cynical critic of revealed religion, he was accounted one of the notable English deists. His works, philosophical and political, are written in an oratorical strain. They are models of polished, pointed, declamatory prose. They deserve to be studied if only for the merit of the style; their matter is of less interest, but their wit retains its edge, and their eloquence its glow. Bolingbroke's collected works were published by David Mallet in 1733-54.

See *Bolingbroke, a Historical Study*, by J. Churton Collins (1886); *Bolingbroke*, by A. Hassall (1888; revised 1915); *Bolingbroke and his Times*, by Walter Sichel (2 vols. 1901-3).

Bolívar, the name of several states and territories of South America.—(1) A state or department of Colombia, which in repeated redivisions of the country has not always held its place. The surface is mostly low and well watered, with many swamps; the climate in some parts is hot and unhealthy. Capital, Cartagena; chief port, Barranquilla.—(2) The largest of the United States of Venezuela, extending from Colombia to the Atlantic, and watered by the Orinoco and its tributaries; area, 90,000 sq. m.; pop. 70,000. The state is frequently called Guayana; for its capital, Ciudad Bolívar, see ANGOSTURA.—(3) A province of the republic of Ecuador; pop. 50,000.—(4) An agricultural settlement of Venezuela, 30 miles NE. of Caracas, founded in 1874 to receive immigrants.

Bolívar, the Venezuelan monetary unit, answering to the franc.

Bolívar, SIMON (named *El Libertador* for having rescued South America from the Spanish yoke), was born in Caracas, in what is now Venezuela, July 24, 1783, and was descended from a noble and wealthy family. He studied law at Madrid, and visited several other capitals, witnessing in Paris the closing scenes of the Revolution. In 1801 he returned to Caracas, but on the death of his young wife he came to Europe again in 1804, and in 1809 visited the United States, from which he returned with the determination to free his country from foreign despotism. Arriving in Venezuela, he at once associated himself with the patriots there; and after the insurrection at Caracas in 1810, he was sent to London with a view to interest the British cabinet in their aims. The British government, however, declaring its neutrality, Bolívar speedily returned. On the declaration of independence by Venezuela on July 5, 1811, war was commenced by the Spaniards, and

Bolívar fought under General Miranda in several successful engagements. The royalists having again obtained possession of Venezuela, Bolívar had to flee to Curaçao; but in September 1812 he joined the insurgents in New Granada, and driving the Spaniards back beyond the Magdalena, recrossed the frontier with a force of 500 men, and proclaimed a war to the death. His army increased with each victory; and on August 4, 1813, he entered Caracas as a conqueror, and proclaimed himself dictator of western Venezuela. Fortune soon deserted the patriots, however; in June 1814 they were routed at Cura, and 1500 slain. Bolívar was compelled to retire to Cartagena, and, after some further service in New Granada, to Kingston in Jamaica, where an assassin, hired by the Spaniards, tracked his steps, but by mistake murdered his secretary. Having visited Hayti, and assembled there the insurgent refugees (1816), Bolívar twice landed in Venezuela; he was finally compelled to flee to Barcelona, and there formed a provisional government. The following two years were marked by a series of conflicts in which the scattered parties of patriots were most frequently beaten. In 1819 a congress was opened at Angostura, and Bolívar was confirmed in the supreme power. Having conducted his army, of which the British legion formed a third, over the almost impassable Cordilleras to New Granada, he achieved the victories of Tunja and Boyaca, and soon afterwards declared New Granada united with Venezuela as a republic, under the name of Colombia. Nevertheless, although Bolívar had a force at least twice as large as Morillo, the dissensions of the patriots prevented any concerted action, and it was only in June 1821 that the victory of Carabobo virtually ended the war in Venezuela; while it was not till July 1824 that the royalist troops were finally driven out of the country. The constitution of Colombia was adopted on August 30, 1821, and Bolívar was chosen president.

In 1822 Bolívar added Ecuador to the republic, and was summoned to help the Peruvians. Bolívar was named dictator of Peru, from which possession also the Spaniards were driven, after more than two years' fighting. In 1825 Bolívar visited Upper Peru, the name of which was changed in his honour to Bolivia. A constitution prepared by him in 1826, at the request of the Bolivians, excited dissatisfaction and even alarm, chiefly on account of its proposal to intrust the executive power to a president for life, without responsibility, and with power to name his successor. In September he intrusted the government of Peru to a council appointed by himself, and returned to quell a disturbance in Venezuela. His personal influence prevailed, and he was re-elected president, in spite of his expressed unwillingness; but meantime, in Peru his famous code had been renounced, and the Colombian troops had been expelled from Bolivia. His assumption of supreme power in August 1828 roused the apprehension of the republicans; the dread of a second Napoleon led to a conspiracy against his life; and in November 1829 Venezuela separated itself from Colombia. In consequence, Bolívar laid down his authority in April 1830, when the congress of Bogotá, now largely made up of his enemies, voted him a pension of 3000 dollars, on condition of his residing abroad. He died at San Pedro, near Santa Marta, 17th December 1830. Bolívar has been described as the Washington of South America. The difficulties of the war of liberation compelled him to assume a dictator's power, but there is no proof that he was ever insincere in his devotion to liberty; and in the service of his country he not only gained no wealth, but freely spent his own large fortune. In

1842 his remains were removed with great pomp to Caracas, where a monument has been erected to his memory; statues have been raised to him at Bogota, Lima, and New York; and the Liberator's centenary was celebrated at Caracas in 1883.

See books by Ducoudré-Holstein (1830), F. Loraine Petre (1910), Mancini (1912). The Spanish pronunciation of his name is *Bolee'var*.

Bolivia, a republican state on the west side of South America, formed in 1825, and deriving its name from Bolívar. Formerly called Upper Peru, it was till 1825 part of the viceroyalty of Buenos Aires. It extends between 9° 30' and 23° S. lat., and 57° 30' and 69° W. long., and is enclosed by Peru, Brazil, Paraguay, the Argentine Republic, and Chile. A portion of the Paraguayan frontier has been for some time undetermined. Its coast provinces Bolivia lost to Chile in consequence of the war of Bolivia and Peru with Chile in 1879-83. Bolivia's case was put before the League of Nations in 1921. A wide region in the north was long claimed by Bolivia. Negotiations during the 20th century have assigned the greater part to Brazil and Peru. The area of the republic is estimated at about 600,000 sq. m. The population is estimated at 3,000,000, of whom about half are Indians.

Surface and Hydrography.—Prior to the treaty of 1884 Bolivia contained the loftiest and most mountainous district of America; but as since then her western frontier has been bounded by the Andes, this claim would now be only partly true. The lofty plateau of Oruro and Potosí, with an average height of 10,000 to 13,000 feet, and an area of about 68,000 sq. m., is enclosed between the Andes proper and the Cordillera Real, to the east. There are also intermediate ranges and isolated groups; and the summits of the western and eastern chains include Sahama or Sajama (a volcano), Illampu or Sorata, and Illimani, all over 21,000 feet high. The great plateau falls into two parts, of which the northern is the more inhabited, the Lake of Titicaca (partly in Peru) and the many well-watered valleys around making the district not so unproductive as its great elevation would otherwise render it. This lake, with an area of more than 5000 sq. m., and a depth of 160 fathoms, encloses several islands, the largest of which was the home of the founders of the empire of the Incas. It lies 3500 metres above sea-level. The Rio Desaguadero, with a course of 160 miles, connects it with the salt lake and swamps of Aullagas or Paria, very much smaller than Titicaca; and somewhat to the west lies the Laguna de Coiposa, a basin covered, in the dry season, with a thick crust of salt. The southern and lower tableland is chiefly a desert, where the mountain streams either sink into the sand, or flood, in the rainy season, what are salt pampas throughout the rest of the year. The Cordillera Real system descends abruptly, on the north, to the plain of the Amazon; but its eastern edge is a series of terraces, sinking gently to the plains of eastern Bolivia, which in the north belong to the Amazon basin, and in the south to the pampas of the Plata. This eastern region is a cradle of both rivers, gathering for the latter the Pilcomayo, with its tributary streams, which flows through the Gran Chaco to feed the Paraguay, and for the former the Guapey or Rio Grande, which afterwards becomes the Mamoré, and unites with the Beni (q.v.) to form the Madeira. See AMERICA, ANDES.

Climate and Vegetation.—Although situated entirely within the tropics, Bolivia, from its varied elevation, possesses a wide range of climate and productions. The regions with an elevation of over 11,000 feet are called *punas*, while the *puna brava* is the region of snow and ice above 12,500 feet. This division includes the whole tableland of Oruro and the loftier mountain peaks. The

climate is cold and dry, but generally healthy, in spite of the cutting winds, the extreme rarity of the atmosphere, and the occasional days of great heat, followed by bitterly cold nights. Vegetation is scanty, and cultivation mainly confined to potatoes, barley, and coarse grasses, which maintain the animals of this zone. Here, and in the higher parts of the next region, the dry and rainy seasons are distinguished, the latter extending from November to March. The *cabezeras de valles* are the heads of valleys descending to the lowlands, in the eastern terraces, between 9500 and 11,000 feet; the deeper valleys, between 5000 and 9500 feet, are called *medio yungas*. The former have a temperate climate, and wheat and maize are produced in large quantities; in the latter, tropical fruits begin to flourish. East of the inner Cordillera lie the *yungas*, or plains under the 5000 feet limit. This district, with its numerous streams, its luxuriant tropical vegetation, its rich forests of valuable trees in the north, and its immense open savannahs in the south, surpasses most countries of South America in fertility and resources. Rubber, coffee, rice, cacao, coca, pine-apples, bananas, tobacco, cotton, and the valuable cinchona are cultivated. The rainfall here is uncertain. Intermittent fevers are confined to the northern plains, where the overflowing rivers and rank vegetation are added to a hot and moist atmosphere. In Bolivia generally the rainy season lasts from December to May.

Animals.—In the *punas* are found the guanaco, llama, alpaca, and vicuña—animals almost as independent of water as the camel—and the chinchilla; in the east, jaguars, tapirs, and other wild animals common to Brazil. The first three are prized for their skins, and are also largely employed as beasts of burden; the vicuña yields a long, soft wool; and the chinchilla skins also form a valuable article of commerce. Large numbers of sheep are herded in the highlands, and of cattle in the plains.

Minerals.—While agriculture and stock-raising have never received proper attention in Bolivia, the development of its mineral resources has always been the most important industry of the country; for its great yields of gold, silver, copper, and tin ores have for centuries given a large profit, in spite of the excessive cost of transport. The mines of Potosí, which have been worked since 1545, are estimated to have produced, up to the present, over £600,000,000 sterling of silver. Since the war of independence (1809–25), the industry has been practically uninterrupted, and specially fostered by favourable fiscal regulations. The want of good roads or accessible seaports, and a lack of better fuel than llama-dung or moss, seriously impeded the work; but the extension of railways, and the discovery of coal in several provinces, help to remove these checks. Consequently a great revival in mining enterprise has been noticeable since 1883, many abandoned mines having been reopened. Potosí and Oruro still produce much; but most comes from Huanchaca, to the south-west of Potosí. Lead and quicksilver are often found along with the silver. Of tin Bolivia yields about one-fourth of the world's supply. Gold-mining has been abandoned, except by the Indians, who carry it on in a primitive way; but the metal is still washed in grains from the rivers of the eastern slope and foot-hills of the Cordillera Real. The rich copper-mines have recently been less worked, chiefly owing to transport difficulties. Other minerals are bismuth, zinc, cobalt, wolfram, antimony, borax, salt, and petroleum.

Commerce, Communication, &c.—From the landlocked position of the republic, its foreign trade labours under heavy disadvantages, which the nature of its great rivers, obstructed by rapids, has increased. Prior to the Chilean war its favourite marts were

the Peruvian port of Arica and its own Cobija, now Chilean. But both Argentine and Brazil having granted gratuitous egress through their ports, a great part of Bolivia's productions then drained through these countries. In order to restore the trade to the Pacific, a railway was made from the now Chilean port of Antofagasta, which forks at Uyuni, in Bolivia, one branch going to Oruro and La Paz, the other to the Huanchaca mines. Another railway runs from La Paz to Lake Titicaca, and thence by Arequipa to the Peruvian port of Mollendo. A third trans-Andine line (1912) connects La Paz with Arica, now a Chilean port. At Tupiza, in the south, is the link with the Argentine railways. Thus the pan-American railway is complete from Cuzco to Buenos Aires. Bolivia has river communication with the Atlantic by the Paraguay and Amazon systems, the former supplemented by a railway across Brazil, the latter rendered practicable by a Brazilian railway (1914) where the Mamore-Madeira is obstructed by falls. There are about 1500 miles of railways, 7000 of navigable rivers, but both rail and river communication is being widely extended. Exports are tin, rubber, silver, bismuth, copper, alpaca wool, chinchilla and vicuña skins. Manufactures are very backward. Rubber, coca, and cinchona plantations attract much attention and capital. Coca is in large demand, both for home consumption and for export.

Population.—The population of Bolivia is a mixture of various races, half-caste Spaniards and Indians, with very few descendants of African negro slaves. About a third of the people live in the towns, the remainder in hamlets or in the *Campaña*. Most of the Indians are civilised. The Quichua and Aymará Indians chiefly inhabit the highlands of the west. The former are direct descendants of the Incas, whose language and manners they preserve, and form 50 per cent. of the pure native population; the Aymará are a kindred race, about half as numerous. They are devout Catholics, mild, apathetic, with more endurance than energy, and are mostly *arrieros*, or drivers of llama-trains, or engaged in llama and sheep raising and rude agriculture. The Chiquito and Mojos Indians of the great north-eastern llanos retain part of the civilisation introduced by the Jesuits in the 17th century. The several tribes of nomadic Indians inhabiting the eastern plains are more or less maliciously disposed towards the Spanish race, but their dislike seldom finds expression in overt acts, and in consequence travel in Bolivia is comparatively safe. The half-bred population is about half as numerous as the pure Indian; the *cholos*, a Spanish and Indian mixture, form the most important element, and to them Bolivia largely owes her independence. The religion of the country is Roman Catholic, but others are tolerated; there are four dioceses, including an archbishopric of La Plata. Education is extremely backward, but is advancing. Sucre and La Paz have universities.

Government, &c.—According to the constitution, the executive is vested in a president, with two vice-presidents, and a ministry; while the legislature consists of a congress of two chambers, the Senate and the House of Representatives, both elected by direct suffrage. In practice, the law requiring the election of the president every four years was for long little observed, the supreme power having been almost invariably seized by successful military commanders. Service in the militia is obligatory. There is also a permanent force of 5000 men. Bolivia is divided into eight departments, not including territories. The seat of government has been repeatedly changed. Sucre is now the nominal, La Paz the real, capital. The chief towns are La Paz (100,000), Cochabamba (30,000),

Sucre or Chuquisaca (30,000), Potosí (30,000), and Oruro (30,000).

History—After a struggle of fifteen years, the battles of Junin, Ayacucho, and the brilliant victory of Tumusla gave to Upper Peru (now Bolivia) its independence. General Antonio José de Sucre called together the first National Assembly, which met at Chuquisaca, or Sucre, and on the 6th of August 1825 independence was declared. The new state received the name of 'República Boliviana' as a homage to its liberator, Simon Bolívar (q.v.); the name was afterwards changed to 'República de Bolivia.' Bolívar was proclaimed father and protector of the nation. His government laid the first basis of the new republic, dictating urgent and opportune measures. Sucre, in Bolívar's absence, assumed the provisional government, and under his wise and virtuous administration important reforms were made, such as new territorial divisions and the organisation of the treasury. Elected president by the Assembly in 1826, he laid before that body the first Constitution, drawn up by Bolívar; but it alarmed the Assembly, which saw in it some monarchical principles. In 1828 Sucre delegated his powers to the ministerial council, but on hearing that the Peruvian forces had invaded the territory, he placed himself at the head of the troops, and after the capitulation of Piquisa fixed the basis for an agreement between the Bolivian and Peruvian Commissioners, afterwards presenting his resignation to congress, which appointed General Andrés Santa Cruz as provisional president. Santa Cruz reorganised the army, promulgated laws, founded universities, and made other important reforms. The General Assembly at La Paz sanctioned the Second Constitution. Santa Cruz formed the confederation of Peru and Bolivia, of which he was recognised at Lima as supreme dictator (1836); but defeated at Yungay, and hearing of Bolivian opposition (1839), he never returned to the country. General José Ballivian was succeeded by General José Miguel de Velasco, who declared himself dictator. He was defeated by General Belzu, who once more restored the constitution of 1839. Don José Córdova, Don José María Linares, and Don José María de Achá succeeded, but the last was deposed by General Margarejo, who declared himself dictator, and was in turn defeated by Colonel Agustín Morales (1871-72). In 1876 General Daza was elected, and it was during his government that the disagreement between Bolivia and Chile took place, when the latter country, before declaring war, occupied the Bolivian port of Antofagasta on the 14th of February 1879, the result being the disastrous conflict between Bolivia, Peru, and Chile, by which Bolivia lost all her sea-coast. As Daza was accused of treason and fled to Europe, General Campero was proclaimed president, and was succeeded constitutionally by presidents Pacheco, Arce, Baptista, and Alonso. La Paz resented the fixing of the capital at Sucre; Alonso fled, and General José Manuel Pando was elected in 1899. Dr Eliodoro Villazon (1909-13) and Dr Ismael Montes succeeded. Troubles arose again under Don José Gutiérrez Guerra. A 'Junta de Gobierno' took over the government in 1920, and summoned an Assembly to elect a president (Dr Saavedra) and reform the constitution. See *Bolivia*, by Paul Walle (trans. 1914).

Bolkhov, a cathedral city of Russia, on the river Nugra, 37 miles N. of Orel. It manufactures leather, gloves, hosiery, and soap, and has an active trade in tallow, hemp, oil, fruit, and vegetables. Pop. 22,000.

Boll, a measure of capacity for grain, &c., used in Scotland and the north of England. In Scot-

land it is usually equivalent to 6 imperial bushels, but in England it varies from that to 2 bushels—the 'new boll.' It is also a measure of weight, containing $\frac{1}{2}$ for flour, 140 lb. The word is pronounced *baw* in modern Scots; being entirely a northern word, it may be distinct from the English *boll* (a swelling, pod, or knob), *bowl* (a round vessel), O.E. *bolla*, and be rather from *bollu*, an old Norse equivalent of the same. See a table of its local values in *Old Country and Farming Words* (English Dialect Society, 1880).

Bollandists, an association or succession of Jesuits by whom the *Acta Sanctorum* (q.v.), or Lives of the Saints of the Christian Church, were collected and published (1643-1794). They received their name from JOHN BOLLAND, born in the Netherlands 1596, died 1665, who edited the first 5 vols., containing the month of January in 2 vols. published in 1643, and the month of February in 3 vols. published in 1658. The vast undertaking had been projected by a Flemish Jesuit, Heribert Rosweyde, and on his death in 1629 his collections were intrusted to Bolland, who established himself in Antwerp, opened a correspondence all over Europe, and associated young men of his order with himself in the work. The suppression of the Jesuit order in 1773 caused the removal of the Bollandist Society to the monastery of Coudenberg, in Brussels, till the persecutions under Joseph II. brought about its dissolution. In 1789 the abbey of Tongerlo in Brabant took up the colossal task of carrying on the *Acta Sanctorum*; but scarcely had the 53d volume appeared in May 1794, bringing the calendar down to October 6, when the French occupation, and their destruction of the MS. collections, put an end to the work. In 1837 a new Bollandist association of Jesuits was formed under the patronage of the Belgian government, which set aside a yearly sum of 6000 francs for this object, and in 1845 the 54th volume appeared. Over 60 volumes have now appeared (the parts published in 1887-1910 being devoted to November); and there is thus a prospect of the completion of this vast work, of which Gibbon has truly said that 'through the medium of fable and superstition it communicates much historical and philosophical instruction.' New editions of the older volumes were published in Venice (1734-70) and Paris (1863-83), and since 1882 supplements, *Analecta Bollandiana*, with facsimiles of the more valuable MSS., at Paris and Brussels. See SAINT; H. Delehaye, *A Travers Trois Siècles* (Brussels, 1920).

Bologna, one of the most ancient cities of Italy, beautifully situated on a fertile plain at the foot of the lower slopes of the Apennines, 82 miles N. of Florence, and 135 SE. of Milan by rail. An irregular hexagon, it is inclosed by a high brick wall, 5 to 6 miles in extent, with twelve gates, and is intersected by the canal of Reno, while, on either side, the rivers Reno and Savena sweep past its walls. The streets in the newer parts of the city are spacious and well paved, with rich and varied colonnades, affording shelter alike from sun and rain; in the older portion, the streets are narrow and dirty, and the arcades correspondingly low and gloomy. The city is adorned with many fine palaces of the nobility, which are rich in fresco-paintings by the great masters. Pre-eminently worthy of notice are the Palazzo Pubblico, and the Palazzo del Podestà. The former contains some fine frescoed rooms and galleries; the latter is interesting as having been the prison and death-scene, in 1272, of Enzo, the son of the Emperor Frederick II., and also as containing the archives of the city. There are numerous and important charitable institutions. The great feature of Bologna, however, is its religious

edifices, which are remarkable both for the beauty of their architecture, and the abundance and splendour of the art-treasures they contain. It has more than 70 churches, the most remarkable of which are San Stefano, which is rich in relics, Madonnas, and Byzantine frescoes of the 11th and 12th centuries; San Petronio—which, though unfinished, is the largest church in the town—a noble specimen of Italian Gothic, with a meridian traced on the floor by the astronomer Cassini, and numerous masterpieces both in sculpture and in painting; San Domenico, where the founder of the order lived and died, and where his tomb has been richly ornamented by Michael Angelo and others; and the cathedral dedicated to St Peter, also rich in works of art. In the centre of the city are two remarkable leaning towers, constructed about the beginning of the 12th century: the Asinella, with a height of 274 feet, and an inclination of 3 feet 4 inches, and the Garisenda, with an elevation of 137 feet, and a lean of 3 feet 2 inches. The university of Bologna, the oldest in Europe, claims to have been founded in 425; it certainly dates as a law-school from the 11th century. Its reputation early became so great, chiefly on account of its school of jurisprudence, that students from all parts of Europe were attracted to it. In 1262 the number receiving instruction is stated to have been 10,000, and it was found necessary to appoint professors specially for the students from each country. Medicine has long been the principal study, and the discovery of Galvanism by one of its professors has shed a lustre on the university, which is also celebrated as the earliest school for the practice of dissection of the human body, as well as for the fact, that for centuries learned female professors have prelected within its walls. The students now number about 3000, and the university still holds a first rank among Italian educational institutions; its eighth centenary was celebrated in 1888. See UNIVERSITIES. Bologna also possesses an academy of music of some note (1805), at which Rossini studied. Bologna has two large libraries containing many rare volumes. There is also an engineering college of note. The Accademia delle Belle Arti is particularly rich in the works of those native artists who founded the far-famed Bolognese school of painting, and it has also some fine specimens of other schools. Bologna has given 8 popes and more than 200 cardinals to the Church. There are some important manufactures, including silk goods, velvet, crape, wax candles, musical instruments, chemical products, paper, cards, and sausages almost as celebrated as its paintings. Pop. (1872) 115,957; (1881) 103,998; (1921) 211,000.

Bologna owes its origin, which is said to be much more remote than that of Rome, to the Etruscans, by whom it was called *Felsina*. It was afterwards, as *Bononia*, the chief town of the Boii, from whom it was taken by the Romans and made a colony (189 B.C.). After the fall of the Roman empire, it passed into the hands of the Longobards, from whom it was taken by the Franks. Charlemagne made it a free city, and the citizens were afterwards invested with the choice of their own judges, consuls, and magistrates. The feuds of the Guelph and Ghibelline factions led in 1506 to the downfall of the republic, and the supremacy of the papal see. In 1796 Bologna was taken by the French, and was constituted the chief town of the Cisalpine Republic; in 1815 it reverted to the pope. In 1848 the Austrians vainly attempted to take the town; but in 1849 they captured it after a ten days' siege. In 1859 the Bolognese sympathised with the national cause, and in 1860 voted, by 1000 to 1, for annexation to Italy. The fertile province of Bologna, with an

area of 1430 sq. m. and a pop. of 600,000, produces much rice and silk. The Bolognese School (see PAINTING) included Fiancia, the three Carracci, Domenichino, Guido Reni, and Guercino.

See Burton's *Etruscan Bologna* (1876), and Miss Coulson James's *Bologna, its History, Antiquities, and Art* (1910).

Bologna, GIAN, or GIOVANNI DA (1530-1608), called 'Il Fiammingo' (The Fleming), was born at Donai, and, settling in Italy, was recognised as one of the great sculptors of the Renaissance. He worked mainly at Florence under the patronage of the Medici. His masterpiece is the fountain at Bologna.

Bologna Flask, or PHILOSOPHICAL PHIAL, is a short, thick, narrow glass vessel, close at one end, and open at the other, which the glass-blower prepares from each pot of metal before employing it in the fashioning of tumblers, glasses, bottles, &c. (see GLASS). It serves the purpose of enabling the glass-manufacturer to judge of the colour and other conditions of the fused glass or metal; and as the flask is not subjected to annealing, it is very friable, and a small angular fragment of any mineral allowed to drop into it, at once causes it to fly in pieces. It is curious to notice, however, that a Bologna phial will bear a very heavy blow on the outside without being fractured.

Bologna Stone, or BONONIAN STONE. In the end of the 16th or beginning of the 17th century, Vincent Casciorolo, a shoemaker of Bologna, made the very remarkable discovery that the mineral now known as heavy spar (barium sulphate), which is found near Bologna (as it is in a great many other places), when reduced to a fine powder, mixed with charcoal, dried, and strongly heated in a covered crucible, is converted into a substance having the property of shining in the dark. Casciorolo mentioned his discovery (1602) to the alchemist Scipio Begatello and the mathematician Maginus, and the latter made the substance (first called by its discoverer 'capis solaris,' but soon from the place where it was prepared, 'the Bologna, or Bononian Stone') famous by the specimens which he sent about. Peter Potier (or Poteras), a French chemist resident in Bologna, first published (1622) a recipe for making it.

The substance is essentially sulphide of barium, but its phosphorescent character depends very much on the way in which it is prepared, and many processes have been described. It shines in the dark only if it has previously been shone on, seeming slowly to give out the light it has absorbed. The now well-known 'luminous paint' is made up of this or of other similar and similarly prepared sulphides. See PHOSPHORESCENCE.

Bolometer, an instrument invented (1881) by Professor Langley for the measurement of the intensity of radiant heat—essentially a Wheatstone's Bridge (see ELECTRICITY), arranged so that no current passes through the galvanometer. The arms of the bridge are made of a substance the resistance of which varies greatly with the temperature. Hence, if one arm be exposed to radiation from which the other is screened, the galvanometer needle will be at once deflected. The instrument may be made much more sensitive than a thermopile. A good one can measure variations of temperature of 1/100th of a degree centigrade, and can detect a variation of 1/1000th.

Bolor-Tagh is a lofty border-ridge of the Pamir plateau, ranging SW. to NE., which falls abruptly to Kashgaria (see ASIA, PAMIR, TURKISTAN). There was near this range an ancient kingdom of Bolor.

Bolsec, JEROME. See CALVIN.

Bolse'na (ancient *Volsinii*), a town in the province of Rome, on the north shore of the Lake of Bolsena (*Lacus Volsiniensis*), 20 miles NNW. of Viterbo. It is now little more than a village; but prior to 280 B.C. it was a place of great importance, forming one of the twelve Etruscan cities. At Bolsena in 1263 a doubting priest was said to have been convinced of the truth of the doctrine of transubstantiation by witnessing the flow of blood from the Host he had just consecrated; and in commemoration of this miracle (the subject of a masterpiece by Raphael), Urban IV. instituted, in 1264, the festival of Corpus Christi. Half a mile from Bolsena are a few traces of the Etruscan city, and many fragments of the later Roman one remain.—The Lake of Bolsena is a fine expanse of water about 10 miles long and 8 broad, but its shores are very unhealthy. It occupies a volcanic hollow. The Marta River carries its waters into the Mediterranean. It has two islands, Bisentina and Martana, which were favourite autumnal retreats of Pope Leo X. See ETRURIA.

Bolshev'iki, the majority party, the more revolutionary of the two sections into which the Russian Social Democratic Party split in 1903, the minority party, prepared for compromise, being called Mensheviks. The Bolsheviks, under the leadership of Lenin, Trotsky, and Tchitcherin, gained the upper hand in November 1917. See COMMUNISM, SOCIALISM.

Bolsward, an old town of Friesland, 15 miles SW. from Leeuwarden. It has a fine Gothic church. Pop. 7000.

Bolton, or BOLTON-LE-MOORS, an important English manufacturing town and parliamentary and county borough in South Lancashire, on the Croal, 11 miles NW. of Manchester. The river Croal divides the town into Great and Little Bolton. It was celebrated as far back as the time of Henry VIII. for its cotton and its woollen manufactures, introduced by Flemish clothiers in the 14th century. Emigrants from France and the Palatinate of the Rhine subsequently introduced new branches of manufacture; and the improvements in cotton-spinning of the middle of the 18th century rapidly increased the trade of the town. Though Arkwright was at one time a resident, and Crompton was born and all his life lived in the parish of Bolton, the opposition of the working-classes long retarded the adoption, in the town, of their inventions—the spinning-frame and the mule. Bolton is now one of the principal seats of the cotton manufacture in Lancashire. Muslins, fine calicoes, quiltings, counterpanes, dimities, &c. are manufactured. There are also extensive foundries and iron-works, bleaching-mills, chemical-works, paper-mills, and dye-works. There are several public libraries, two museums, town cemeteries, parks and recreation grounds, town-hall (1873), market-hall, fish-market, slaughter-house, sewage farm, exchange, mechanics' institute, technical and art schools. Water is brought from Entwistle Moor, a distance of 5 miles. Bolton is a principal station on the London and North-western Railway. It is the birthplace of the daily evening press (*Bolton Evening News*), and has several evening and weekly newspapers. During the Civil War the Parliament garrisoned Bolton; in 1644 it was stormed by the Earl of Derby, who was beheaded there in 1651. A canal was made from Manchester in 1791. Since 1832 it returns two members to parliament. Pop. (1871) 92,655; (1881) 105,973; (1911) 180,851; (1921, in holiday season) 178,678.

Bolton Abbey, Yorkshire, is situated in a highly picturesque district on the river Wharfe, 6 miles E. of Skipton, and 21 NW. of Leeds. Founded for Augustinian canons about 1150, it
